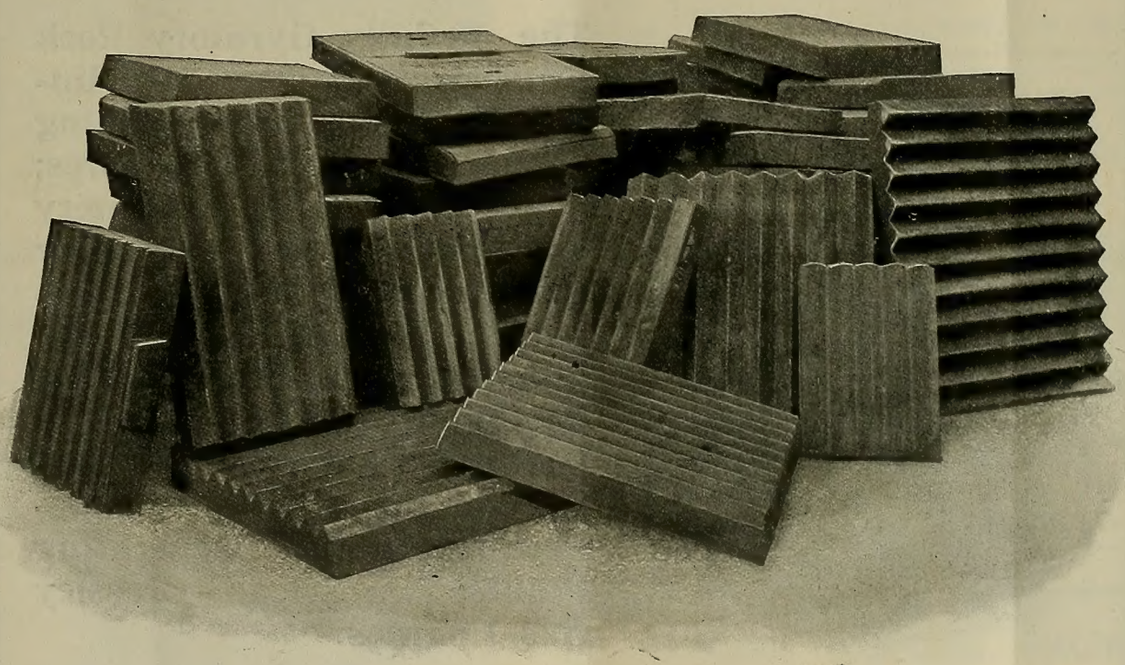
"TAYLOR MADE"

MANGANESE STEEL

ROCK BREAKER SHOES AND DIES AND LINERS do more work, last longer, wear better and give less trouble than any other Crusher Wearing Parts on the market.

Computed by length of service they are most economical, although initial cost may be higher than that of some of the cheaper grades of steel.

It's not what you pay, but what you get for what you pay, that counts in mining machinery where resistance to abrasion is a prime essential.



What we say of

"TAYLOR MADE" MANGANESE STEEL CRUSHER PARTS

Is equally true of "Taylor Made" Manganese Steel Dredge Bucket Lips and Teeth, Screens, Rolls, Roll Shells, Dipper Teeth, Sprockets, Gears, Tumblers, Rollers, Pins, Bushings, Mine Car Wheels—of which we make every variety except the chilled cast iron wheel. In many years actual experience on the field, in every possible condition of service, "Taylor Made" Manganese Steel Castings have proved the best for Heavy Mining Work.

For some uses we make and recommend Nickel Steel, Carbon Steel, or "Taylor Special" Castings.

DON'T EXPERIMENT--JUST BUY THE Wilfley Concentrator.

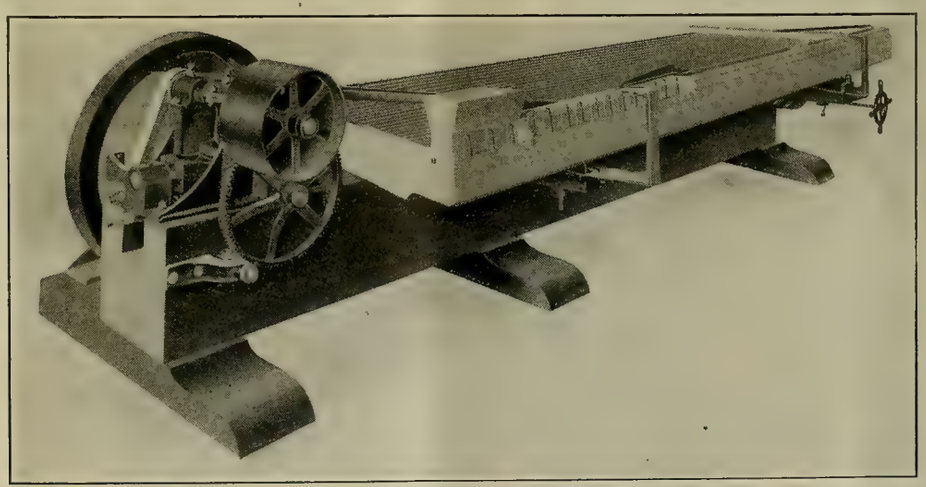
After ten years of success, during which time the Wilfley Concentrating Table has been used in nearly every mining district of the world where the ore will concentrate and has established its reputation for reliability by actual performance, is it necessary to go back to the beginning and say that the

WILFLEY CONCENTRATING TABLE

"SAVES EVERYTHING THAT A GOLD PAN CAN SAVE?"

It seems as though everybody must know it. But it is a fact, and we repeat it.

Do you think that one company would purchase over 500 of these tables if they did not consider them the best? They tested them thoroughly against all other known machines before placing their orders.



No. 5 WILFLEY TABLE.

OUR No. S 6 BULLETIN CONTAINS VALUABLE INFORMATION. Sent on Request.

WE CAN SUPPLY YOU WITH

Cyanide, Chlorination, Stamp and Concentration Mills, complete.

When you are in the market for anything in our line, write or call on any of our branch houses and your inquiries will be promptly attended to. We have in our employ competent engineers in every department who will gladly give you estimates on anything you want in the mining machinery line.

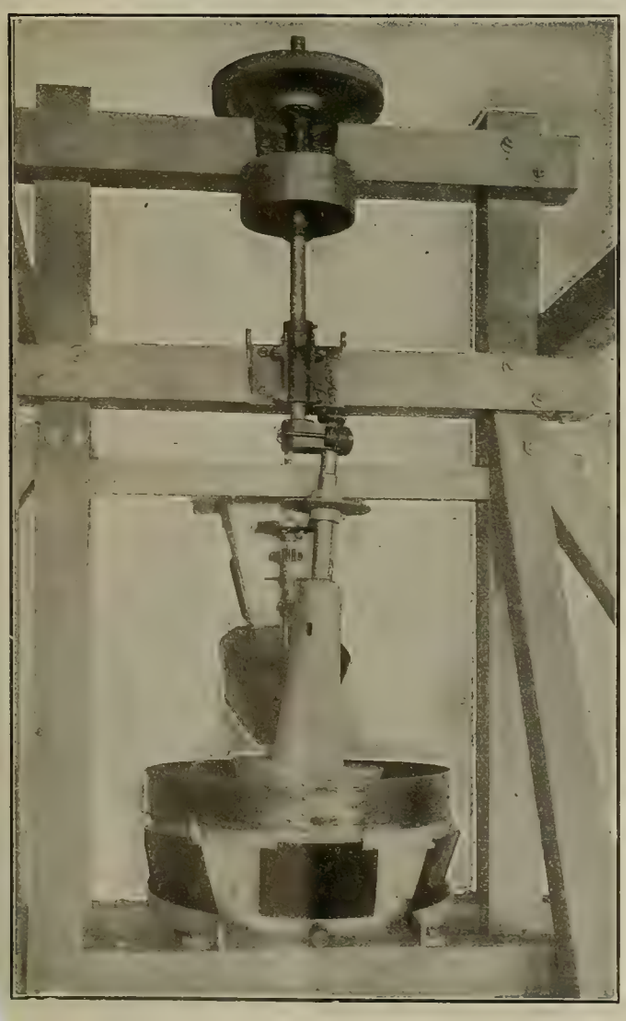
Bullock Electrical Apparatus for all Purposes



THE BEST WAY to Treat Slimes is NOT TO MAKE THEM.

DO YOU KNOW that hundreds of thousands of tons of ore that defied concentration with the stamp mill have been successfully concentrated after being crushed in the KINKEAD MILL?

DO YOU KNOW that tens of thousands of dollars have been taken out of the waste dumps of the Bonanza Mines of the Comstock with this Mill: rock so low in value that it was used to grade the streets with?

DO YOU KNOW that thousands of tons of hard quartz from the lower levels of the Comstock have been and are being successfully treated by the Kinkead Mill to-day?

DOES IT INTEREST YOU TO KNOW that we are operating six mills and six concentrators with less than 20 Horse Power, and that as far as ease of installation, economy in power and wear, and in even quality of pulp delivered, is concerned, the Kinkead Mill is as far ahead of other mills as the Pullman car is ahead of the stage coach?

LASTLY, DO YOU REALIZE that crushing by percussion is wrong in principle, and that crushing by a pressure is the correct way?

IF YOU WANT TO KNOW MORE about what the Kinkead Mill can do, write us.

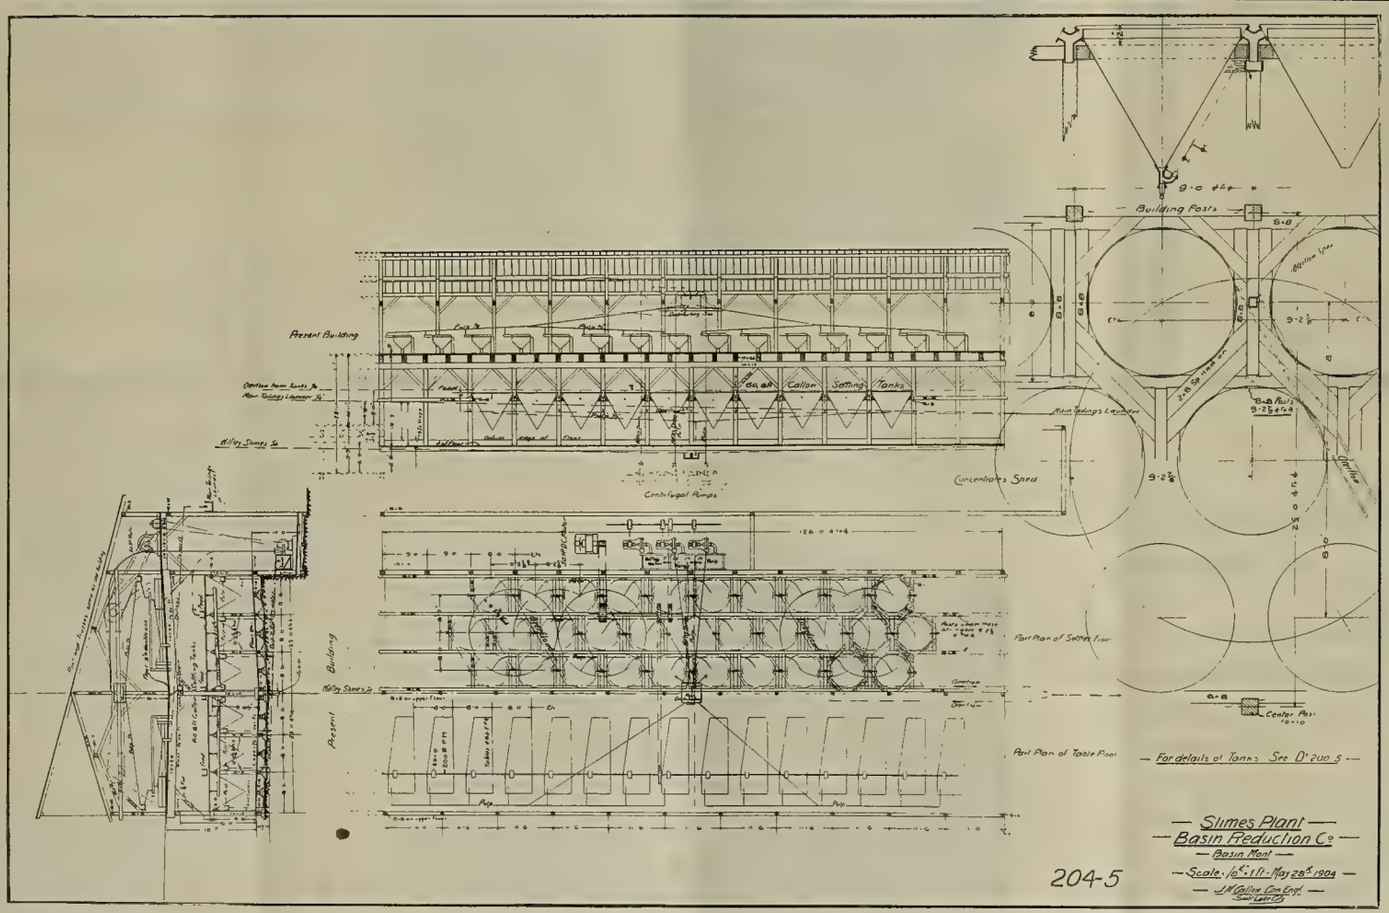
Sheet Metal Works.



THIS PLANT is treating 1800 gallons per minute of slime overflow from the Wilfley feed tanks, and also the dirty water from the back ends of sixty-five Wilfley tables. This supply carries 41 grams of solid matter per gallon, and the overflow gives 16 grams. The recovery of solids is 62½%, of copper 78% and of silver 75%. The thickened pulp is treated on thirty Wilfley tables and yields from 250 to 300 tons of concentrates per month, representing from 3% to 3½% of the total copper output of the plant.

WHAT ARE YOU DOING WITH YOUR SLIMES?

150 TANKS NOW IN USE. The following are using the "CALLOW" tank with success; write to them: The Basin Reduction Co., Basin, Mont.; Boston & Montana Co., Great Falls, Mont.; Hecla Mining Co., Wallace, Idaho; Guanajuato Mining Co., Guanajuato, Mex.; Uncle Sam Mining Co., Eureka, Utah.

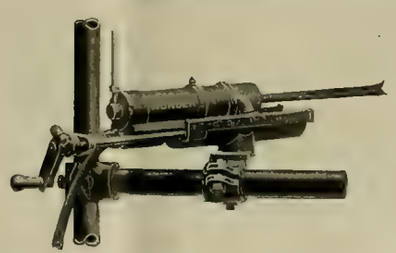
—OUR—

BIG WONDER AIR HAMMER ROCK DRILL

Is worthy to be classed among the labor savers and deserves the attention of all economical mine operators.

Our Little Wonder Air Hammer Rock Drill is a Practical Machine; so is the Big Wonder Mounted Drill.



The Following are Some of the Many Advantages of the Machine:

1. One-fourth of the air consumption of a 2¼-inch Piston Drill.
2. Practica ly no repairs.
3. Strictly one man drill.
4. One-third cost of installation of piston drill.
5. Nothing complicated to get out of order.
6. Will do more work for less money than any machine on the market.

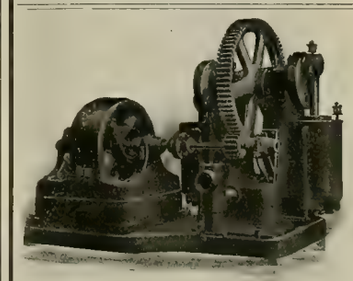
Rand, Straight-Line, Class C Compressors

Our Class C, Straight-Line, steam-driven compressor is particularly desirable where a machine must stand very hard usage, be moved from place to place, and receive but little attention. It is exceedingly compact, self-contained, simple in construction and easily transportable. For these reasons, it is especially suitable for prospecting work and for contractors' use.

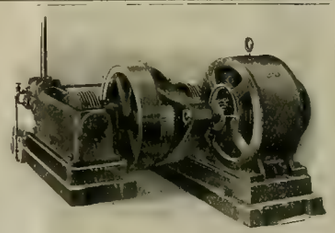


"Imperial" Type II Compressor

Geared to Electric Motor.

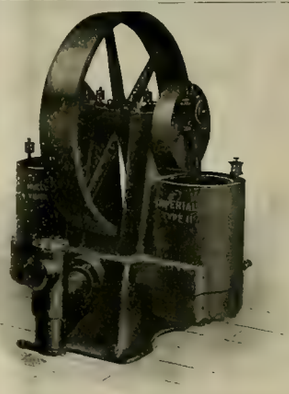
Rand, "Imperial," Type 10 Compressors, Steam Driven

The "Imperial," Type 10, steam-driven compressor is our latest model. It is of the duplex pattern, employing a heavy box bed with the steam and the air (or gas) cylinders at opposite ends, and the balance wheel located nearly in the center. It is self-contained, self-oiling and requires but little attention.



"Imperial" Type 10 Compressor

Noiseless Chain Drive, Electric Driven.



Rand, "Imperial," Type II Compressors

The "Imperial," Type 11 compressor is especially adapted for use in machine shops, foundries and other industrial establishments where but little attention can be given to a compressor.

Its principal features are compactness, simplicity and strength. It has two vertical, single-acting air cylinders, and very long trunk pistons that act as guides for the lower ends of the connecting-rods. By this design, stuffing-boxes and crossheads are eliminated, and a minimum number of bearings required. The cylinders are made both duplex and compound, are thoroughly water-jacketed and provided with hooded heads. They are cast in one piece with the frame, thus insuring the utmost rigidity. The valves, both inlet and outlet, are of the vertical, poppet type.

IF YOU ARE THINKING OF BUYING OR SELLING MINING STOCK, CALL AND SEE US.

If you want some good mining stock, call and let us explain to you something about the Tonopah Berkeley Mining Company.

J. W. JAQUITH & CO., Rooms 874-6-8 James Flood Bldg. (Member of the San Francisco & Tonopah Mining Exchange.)

TELLS IT ALL

HYDRAULIC RAMS

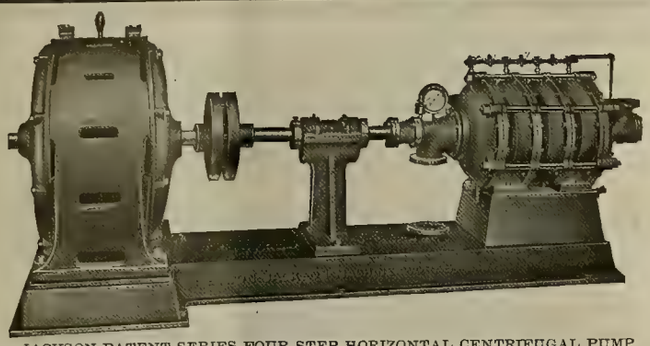
COLUMBIA ENGINEERING WORKS PORTLAND OREGON U.S.A.

Our New Catalogue "R"

DESCRIBES OUR HYDRAULIC RAMS TELLS WHAT THEY CAN DO

The 48-inch Phillips Hydraulic Ram of our manufacture has 25 times more capacity than any other Ram known.

They make mines out of undeveloped gravel beds heretofore thought inaccessible.



JACKSON PATENT SERIES FOUR STEP HORIZONTAL CENTRIFUGAL PUMP FOR RAISING WATER 800 FEET.

PUMPS

THIS CUT illustrates one of our high head centrifugal pumps direct connected to a Westinghouse induction motor and designed to operate against a head of 800 feet, discharging 650 gallons per minute. This pump under test gave an efficiency of 76% and is now operating in one of the largest mines in the West.

We have been building centrifugal pumps for the last twenty-five years and believe we have attained the highest state of the art. We guarantee to raise water to an elevation of 2000 feet or more with practically the same efficiency as a reciprocating pump. The first cost is much less and the expense of maintenance reduced to a minimum.

OUR HIGH HEAD MINE SINKING CENTRIFUGAL PUMPS are especially adapted for unwatering mines and sinking shafts.

The Slogan of the CAMERON—"Character the Grandest Thing."
CAMERON PUMPS. Often Imitated, Never Equaled. Imitation the Sincerest Flattery.

ANNOUNCEMENT! To Users of CAMERON Pumps and the Public Generally:

We have withdrawn our agency from the Mine & Smelter Supply Co., and they no longer represent us; nor are they authorized to sell, as our agents, any of our pumps or repair parts.

We take pleasure in stating that we have transferred our agencies to and are now represented by—

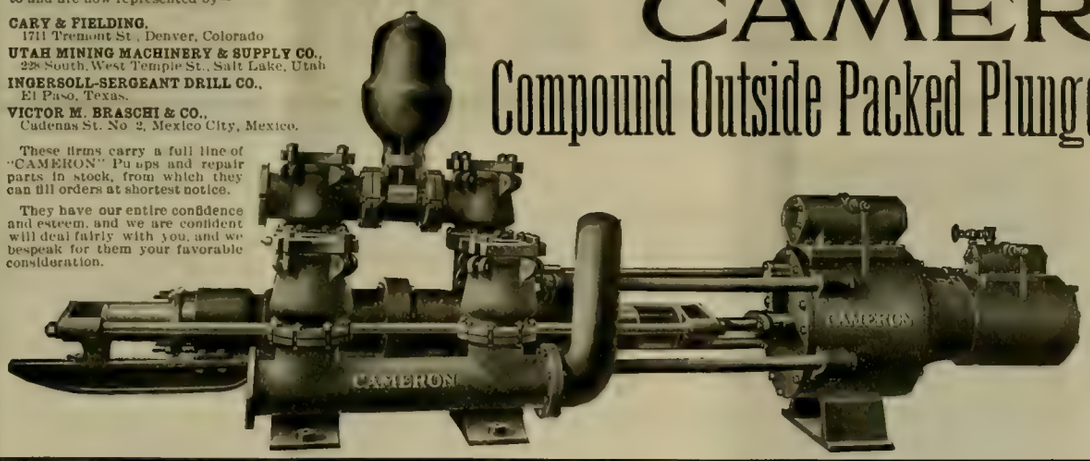
CARY & FIELDING,
1711 Tremont St., Denver, Colorado
UTAH MINING MACHINERY & SUPPLY CO.,
228 South West Temple St., Salt Lake, Utah
INGERSOLL-SERGEANT DRILL CO.,
El Paso, Texas.
VICTOR M. BRASCHI & CO.,
Cadenas St. No 2, Mexico City, Mexico.

These firms carry a full line of "CAMERON" Pumps and repair parts in stock, from which they can fill orders at shortest notice.

They have our entire confidence and esteem, and we are confident will deal fairly with you, and we bespeak for them your favorable consideration.

CAMERON

Compound Outside Packed Plunger Pot Valve Pump



Designed and built especially for use in

MINES

having acid water and heavy lifts.

Water cylinders of hard, close-grained iron, wood-lined if desired or of bronze if necessary.

THE SLOGAN OF THE CAMERON—"CHARACTER THE GRANDEST THING."

To touch again on character—

The character of a CAMERON PUMP has made the CAMERON reputation, and to build up this character and establish this reputation we have had to be exceedingly particular in building our pumps.

To maintain both character and reputation we look to it that every ounce of metal used in a CAMERON PUMP is OF THE BEST. We see to it that every ounce of this "BEST" metal is placed where it will do the most good—to offset wear and tear.

Then again, a CAMERON PUMP is built so as to work along the line of least resistance—few working parts; because, the fewer the working parts and the less power to move them—the heavier we can make them—in order to stand the strain of long continued hard service.

NOWHERE—and CAMERON PUMPS are used EVERYWHERE—has a CAMERON PUMP failed in its duty, or in its ability to work up to full given capacity in situations or under conditions for which it was proportioned and guaranteed.

Truly we have found "Character the grandest thing."

Our new and complete Catalog "R" gives full information about our pumps. Send for it.

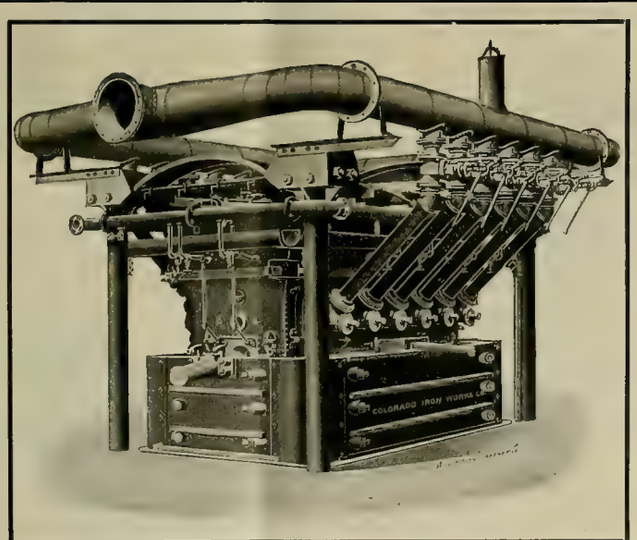
ORE SMELTING EQUIPMENTS ORE MILLING MACHINERY

DENVER, COLO., U. S. A.



C.I.W. 36x108 IN. SILVER-LEAD FURNACE.

THE SMELTING OF ORES.

WE began building Smelting Furnaces and Equipments in 1879, and since that time we have held the foremost position among manufacturers in this special field.

The main reason for the superiority of our smelting furnaces over those of other firms is that we DESIGN and BUILD each of our furnaces especially for each order as it is received. We have no "stock" furnaces, and each furnace has an INDIVIDUALITY and CHARACTER all its own that readily distinguishes it as a COLORADO IRON WORKS CO.'S product.

If contemplating smelting operations, write us; we will be glad to help you in any way we can. Send for descriptive literature.

COLORADO IRON WORKS COMPANY, DENVER, COLORADO.

Scientific Treatment of Boiler Scale

What Scale Does

Do you realize how much the accumulation of boiler scale costs you? It forms on your boiler between the fire and the water and absorbs the heat. One-sixteenth of an inch of scale will add 12% to your fuel bill in one year. A much hotter fire is needed to generate the required amount of steam, and the unequal contraction and expansion of your boiler thus caused materially weakens the joints, seams, and rivets. Expensive repairs result, and, very often, considerable loss of time in making these repairs.

Chemistry of Scale Formation

All feed-waters contain scale forming mineral matter in solution. This mineral matter is precipitated or deposited in the boiler during the process of evaporation, the water passing off as steam and the solids remaining in the boiler and forming a hard, heat-absorbing crust. This is a chemical process, governed by unchanging laws. The only practical way of changing this process is through the use of the right chemical reagents to combine with these solids and either throw them into solution, or form of them friable substances. The nature of the scale-forming combinations in feed-water varies according to the soil and rocks through which it passes. For instance, mine water holds in solution very different combinations from artesian well water. Consequently, each different feed-water requires a special and individual "diagnosis" and "prescription."

Free Chemical Analysis of Scale

You take long chances when you use a boiler compound that is made on the "cure-all" principle. It may be the very thing your boiler does **not** want. Instead of preventing, it may assist in the formation of scale or it may cause foaming and priming. Even if it removed the scale, it might pit and weaken your boiler. The only reliable and effective method is to have the right chemical reagents compounded specially for you. Before this can be done your case would have to be looked into by our expert chemists, and when their analyses and reports are completed, we would be in a position to prescribe the exact combination of chemicals required. These chemicals, so prepared, are shipped by us under the trade mark

Lord's Boiler Compounds

These preparations are all put up in the form of a dry powder. There is no water to pay for, no excessive freight charges, no leakage, or no drums to return.

Send us a sample of your boiler scale. Our expert chemists will analyze it, and we will send you some valuable information showing you how we can save you money and trouble. We make no charge for this and it obligates you in no way. Fill out the coupon and send it with the sample of scale to-day.

Progress by Disaster.

At a dinner given recently by a technical society an engineer made the statement that one of the most potent factors in engineering progress had been disaster. His remarks referred more particularly to the progress in civil engineering, but the statement applies with considerable force to mining as well. The old-time methods of twenty-five years and more ago have to a great extent been changed and better methods devised and applied. There has been published herein the past two weeks a brief description of the methods in mining and milling practice on the Homestake belt in South Dakota during its early history, and showing how, by a process of evolution—suggested and necessitated by frequent disaster — the methods have been changed and adapted to existing conditions until methods of mining have been evolved which have no superior at present in the world. The same difficulties remain to be overcome at many other mines, where the old-time ideas still prevail. In many instances these methods are considered necessary, owing, perhaps, to the low grade of the ore, but any mining method which at first is easily applied and is for a time satisfactory, but which eventually results in disaster, is not the best method. Usually all that has been saved by short-sighted economy is swept away and lost by the disaster which cannot be averted, and which is directly attributable to the method. Caves in mines in many instances may be averted, if proper methods of mining be applied. If these methods be too expensive the management may have several working schemes from which to choose. He may decide that all the ore cannot be recovered by a certain method and that the loss of ore will be less than the increased cost of applying another method which would permit the removal of all the ore, but any method which renders the mine safe while extracting all the ore possible at the least cost is the best method, and is the one which should be adopted. While engineers profit by their own failures and those of others, there are those, unfortunately, who do not appreciate the lessons taught by disaster and who continue to undertake to outwit nature in the same old way and always with the same inevitable result.

Waikino Mills, Waihi Gold Mining Co., New Zealand. (See Page 12.)

THE proposition to reorganize the Horseshoe Mining Co. of South Dakota, if carried out along the lines suggested, as published locally, will do much toward placing that company on a more substantial basis. The Horseshoe is the second largest mining concern operating in the Black Hills of South Dakota. Since its organization the affairs of the company have been more or less involved, one of the drawbacks being excessive capitalization. That the property has merit no one acquainted with its resources doubts. To add to the other unfortunate combination of circumstances the mill at Terry, which cost about half a million dollars, burned the latter part of May.

THE explosion of a large amount of dynamite in a thawing house at the Findley mine in Cripple Creek district, Colo., a few days since, the cause of which is a mystery, has once more started a discussion on the vagaries of nitro powder. The building used for the purpose was a light frame structure and the only heat applied was said to be steam from the boilers, 50 feet or more distant from the thawing house. The building was said to have been locked at the time, and contained 300 pounds of powder. Steam has always been considered a fairly safe means of thawing powder, though there is danger in the use of steam of raising the temperature both too rapidly and too high. What is generally acknowledged to be the safest means of thawing nitro powder is warm water. If the powder be placed in a closed recep tacle, and gently heated by warm water, no explosion has ever been known to occur, but the direct application of steam to the warning device might induce a rapid rise in temperature. Just the character of the device used in the instance above mentioned is not known, therefore it is impossible to give more than a probable cause for the explosion. It is simply another illustration of the great care necessary in handling dynamite, and it will doubtless result in the exercise of even greater care in the employment of powder thawing devices in Cripple Creek district.

THE suit of the Federal Mining Co. v. the Bunker Hill & Sullivan Co., recently brought in the Cœur d'Alene district of Idaho, would seem to place F. W. Bradley, who was lately elected to take the management of the plaintiff company, in an embarrassing position, as Mr. Bradley is president and a large stockholder in the Bunker Hill & Sullivan. This is another of the already noted apex suits on the famous lead-silver vein of the Cœur d'Alenes. The Federal Co. sues for $1,000,000 claimed to be due it from the defendant company for the extraction of ore from a portion of the vein, claimed to belong to plaintiff company because it apexes in one of the latter's claims. The Bunker Hill & Sullivan vein is a broad lode, the foot wall of which is usually, if not always, well defined, but the hanging wall is determined wholly by commercial considerations, the ore occurring in the form of an impregnation of the country quartzite, and being mined as long as it is profitable to extract and concentrate it. At one point in one of the Federal Co 's claims it is understood that this indefinite and uncertain hanging wall cuts across one corner of the claim—therefore the suit. Mr. Bradley, upon being informed of this new litigation, promptly tendered his resignation as manager of the Federal Company, and also as director in the Tacoma and Selby smelters, as all of these enterprises are identified with the American Smelters Securities Co. It is presumable that he had no knowledge or intimation of impending new suits when agreeing to accept these responsible positions with the Federal and the Smelting Companies.

Mining in Mexico.

During the past ten years Mexico has come rapidly to the front as a possible field for profitable mining investment. For many years mining in that republic was not looked upon with as favorable an eye by American and British capital as at present. In fact, investments generally of foreign capital in Mexico were considered risky, to say the least. The broad and liberal policy of the Diaz government has changed this and opened the door of Mexico to foreign investment, and capital invested in Mexican enterprises is not only as safe as elsewhere, but these investments are often unusually attractive in some respects. Throughout Mexico there are old mines and undeveloped mineral resources. Many large as well as small mines are in actual and profitable operation, affording a wide variety of conditions, and great advances have been made in metallurgy in the treatment of Mexican ores. There are many who think that the most desirable mining property in Mexico is an old mine—"la mina antigua"—a mine worked so long ago that the oldest inhabitant knows nothing of it other than its whereabouts and the traditional stories of its fabulous wealth. The average modern miner feels himself so far superior to the "ancient" Mexican that he generally thinks that if he can only come into possession of one of these old mines he can quickly—by reason of his superior knowledge and experience—put it on a paying basis again. In many instances this is fallacious reasoning. The old mines were worked in the interest of men of large influence in their day, and the laborers were generally peons—slaves, in fact—to whom was paid, if anything, the merest pittance. Thousands of these poorly paid workers delved in the mines, building fires at the rock faces, groping through the suffocating smoke and dashing water upon the heated rock surfaces to disintegrate the hard ore, which, when recovered, was laboriously packed on their backs to the surface through long tunnels or up hundreds of feet of notched logs, called by the Americans "chicken ladders." The work of the metallurgist was laborious, crude and slow, but in most cases satisfactory. The efficiency of the labor was certainly not high, but it is equally certain that it was not expensive, even comparatively. For these reasons old Mexican mines yielded large net returns to their fortunate owners, and mines of very low grade could be profitably worked under the conditions existing at that time, particularly where the mine owners also owned a large rancho in the valleys, where all that was required for existence of man and beast was raised or manufactured and where the labor was also performed by peons.

With the ancient Mexican mining was a business which he brought to a high state of perfection in his day, and although not comparable with modern methods—even Mexican modern methods—he was enabled to perform a great work, as the wonderful extent of the development of some of the old mines testify.

Many of the old mines were phenomenally rich, such as some of those at Zacatecas, Guanajuato, Queretero and elsewhere throughout the republic.

Until the water line was reached the ancient Mexican could cope with almost any problem in mining, and in some cases long drainage tunnels were driven to facilitate mining, but when he passed below a possible drainage level in a wet mine his work came to an end, whether the mine were rich or comparatively poor.

The great low grade mines of Mexico can be again worked with profit, in many instances, by the introduction of modern machinery and mining methods, and the metallurgical practices of to-day will extract a far larger percentage of value than was obtained by the ancient miner except with the freest kind of ores, but it should be remembered that even these advantages scarcely offset the low costs under the old peonage system of the ancients.

There are mines in Mexico worked to the water line which were rich. Many of these can be and have been reopened and successfully worked by reason of the high efficiency of American pumping machinery and the superior management of American engineers. Other mines which were profitable above water level are found low grade, base and difficult of treatment in the sulphide zone. Unusual conditions and difficulties exist in many localities in Mexico due to climate and topography, and the truth should be recognized that mining in Mexico is not greatly unlike mining in the southwestern part of the United States, and that each mine must stand upon its individual merit and cannot borrow any real value from its rich neighbors, nor from the traditional tales of great wealth in the past. There are engineering and metallurgical problems—some of them novel—to be worked out, and these are being rapidly solved by American engineers. The difficulties of transportation are being remedied by the construction of railways, and nothing aids more materially than the liberal laws under which Mexican mines are at present operated.

In Mexico the extralateral right is unknown. All mining locations are in square units—the pertenencia, 100 meters square—and a mining property usually comprises a greater or less number of these units. There are many phases of Mexican mining law which could be adopted by the United States with advantage to the industry. No assessment work is required on claims in Mexico, but a tax is fixed and must be paid. There is no evasion of this tax—as in the case of the annual assessment, which is too often evaded in the United States for the good of the industry. As a consequence, those mining in Mexico actively develop the claims upon which they are paying taxes or, if considered not worth development, the claim is relinquished to the Government, and is again open to the next comer. There is no doubt that the Mexican mining laws are in many ways superior to those of the United States. The laws are favorable to development of the Republic's resources, but there are other conditions which tend to retard the extension of mining operations, as well as to make many enterprises commercial failures which should be profitable concerns. These are the overcapitalization of properties and the top-heavy management—an official staff at the mine large enough to operate a Government, with "Home Offices" which absorb a large share of what should be stockholders' profits, for it is needless to say that unincorporated companies, or close companies, and those owned and operated by individuals are not afflicted with the expensive home office attachment, nor is the official staff larger than is really necessary for the proper conduct of the business.

IT is now said that there is a reasonable probability of the construction of the deep Cripple Creek drainage tunnel, the estimated cost of which is placed at $750,000, of which about $500,000, it is reported, has been secured. The value of this tunnel to the mining industry in Cripple Creek district is almost incalculable. In fact, the past experience in this district has shown that very few mines can hope to operate at any considerable depth below the present drainage level of the El Paso tunnel, and even if it were possible to install pumping machinery sufficient to handle the vast volume of water found in this zone of saturation it is good business to drain the ground by means of the proposed tunnel for the reason that it can be more completely and far more economically done by the adit.

OF all the accidents occurring about mines, the collapse of head frames is one seldom or never heard of. In the building of these structures the factor for safety is usually so absurdly large that one has seldom or never been known to collapse.

CONCENTRATES.

SLIMY ORES treated by the cyanide process, where salt water is employed, usually give less trouble in settling the slimes than where fresh water is used.

THE Brandt drill is made in Europe. It is operated by water under a high head which forces the bit against the rock while it slowly turns, cutting away the rock.

MINING COMPANIES incorporated under the laws of one State, and operating their mines in another, are amenable to laws of the State in which they are operating.

THE price at present paid for Joplin, Mo., district zinc ore ranges from a basis of $39 to $41.50 for ore containing 60% zinc. Occasionally prices go as high as $43.50 to $45.

WHEN amalgamating in the battery it is generally advisable to use as little water as possible—enough to clear the pulp out and make an even and free flow over the plates.

WITH a proper arrangement of hydraulic classifiers and concentrating tables in gold mills, there is usually little use for a canvas plant to concentrate slimes from the tables.

MANGANESE occurs in a great variety of rocks, usually in small amount, but in some rocks, such as the cherts of the Coast range of California, is abundant, and in some instances forms veins of commercial value.

IT should be the duty of the superintendent or foreman of the mine to investigate carefully the cause for all missed holes. By ascertaining the cause, it may be possible to obviate their frequent occurrence.

A SULPHIDE is a combination of a metal with sulphur and a sulphate is a combination of a metal with both sulphur and oxygen. Sulphuric acid is merely the combination of sulphur one part and oxygen three parts with water H_2O, forming H_2SO_4.

IF it is necessary to unwater the old workings of the copper mine, it would perhaps pay to run the water through boxes containing iron and tin scraps. In this way considerable copper may be recovered, if the water in the mine contains much copper.

CHROMIUM, commonly called chrome iron, occurs almost exclusively in dark basic rocks, and notably in serpentine, also in dunite and peridotite. The ore is found in segregations of solid ore and in grains scattered through the matrix. It may be concentrated readily by water.

UNDER a head of 410 feet, each miner's inch of water (1.5 cubic foot per minute) will develop 0.99 H. P. Under a head of 650 feet, 1 cubic foot of water per minute will develop 1.04 H. P. Under a head of 410 feet, the discharge from a 1-inch diameter nozzle will be 5.31 cubic feet per minute.

IF the mineral is thought to be heavy spar (baryta), fuse a small quantity of the pulverized mineral with sodium carbonate and place the mass on a piece of clean silver and moisten with a drop of water. If the mineral is sulphate of barium (baryta) it will color the silver black—a black silver sulphide.

IN pyritic smelting if the height of a column of ore be too high the condensation of volatile sulphur in the upper part of the column will ultimately give trouble. If the fire works its way too far upward it has a tendency to slag the materials of the charge and the result usually is that the descent of the charge is retarded or prevented altogether.

IN roasting ores an oxidizing roast is one which leaves the gold present in metallic form and the silver either metallic or in the form of sulphate. A "dead" roast is accomplished by raising the heat, by means of which the oxidizing roast is continued until the sulphates of iron and copper are decomposed. Lead sulphate is not decomposed and usually the silver remains as sulphate.

ALMOST without exception the rich ore bodies of the Comstock lode at Virginia City occur as segregations in large masses of barren or comparatively barren quartz. These quartz masses have formed in the much altered andesites which lie on the footwall diorite of Mount Davidson. There are also ore bodies in the diorite, but these are mostly low grade and rather base, containing iron and copper and lead sulphides, etc., beside low values in gold and silver.

THE distance at which a mountain may be seen depends upon the point of observation and upon the clearness of the atmosphere. In dry countries it is usually possible to see great distances—150 to 200 miles, and even farther, when the air is particularly clear. Colorado, Wyoming, New Mexico, Arizona, southern California and the Great Basin region are noted for the purity of the atmosphere and the great distances through which objects may be distinguished.

IT is a mistaken idea that one may locate mining claims wherever gold is found. A few days since gold was reported found in the gravel brought up by the sand pump in drilling a well at Carson, Nevada, and a number of men at once began staking out claims. Mining claims may only be taken on the unoccupied public domain. Private property is not subjected to the laws under which mining claims are taken.

PRODUCER GAS is used as motive power to drive gas engines, and also for fuel for heating purposes and in furnace work. In the last its use is increasing. Producer gas is made in what are known as gas producers, by passing a mixture of steam and air through an incandescent bed of fuel in a closed producer. The admixture of steam and air must be in the hands of an experienced man or the fire may be extinguished or a poor quality of gas made.

THERE is no longer an arbitrary footage of ground excavated in the performance of assessment work. The work may be estimated by day's labor actually performed at the going wages in the camp where the claim is situated, the amount of work done in a day being equivalent to an ordinary shift's work. The cost of improvements in the way of buildings or other structures, ditches, necessary roads, machinery and pipe lines may also be counted as assessment work. Tools do not count.

ALTHOUGH carbon, manganese, chromium oxide, nickel and several other mineral substances give extreme hardness to steel, the percentage of the mineral used must be just right to accomplish the desired result. Too great an amount of any of these minerals in the alloy will usually produce an entirely different result from that resulting from the introduction of the proper proportion. When the carbon in steel—drill steel, for instance—is burned out by overheating, the steel becomes worthless as a tool, and the burned portion must be cut off.

IN copper mines, where the water is very corrosive and rapidly destroys the iron and steel with which it comes in contact, it seems that the damage to air and water pipes might be overcome by substituting copper pipes for those of iron commonly in use. At some of the mines of Butte, Mont., wooden pipes lined with lead have been put in, owing to the rapid corrosion of iron pipes by the acidulated water and the replacement of iron by the copper. Copper, which thus replaces the iron, has little or no cohesive strength, and the pipe in time will fall to pieces of its own weight.

WHERE ores containing arsenic and antimony are roasted, preparatory to treatment by the cyanide process, great care must be exercised in roasting, particularly in the early stages of the roasting. The temperature must be kept down to a low red heat, as if at first the heat be very high, certain stable compounds of arsenic and antimony are formed, which may make it impossible to extract the gold and silver values by cyanide solutions. On such ores, bromo-cyanide has usually a better effect than with simple cyanide solutions. An extraction of 6% to 7% greater is often possible where the bromine is used.

THE duty of a pound of nitro-powder depends entirely upon the manner in which it is used and upon the character of rock to be broken. An experienced miner who understands placing his holes will break more rock with a given amount of powder than he whose holes are pointed more for convenience in drilling than for the purpose of breaking rock. An expert will rarely overload his hole, while the inexperienced man almost invariably does. A hole that is overloaded will often blow off the collar and leave a large amount of the hole in solid rock. The inexperienced miner argues that he did not use enough powder and the next time uses more instead of less powder.

MAGNETISM is a property possessed by several minerals. The most important are iron, josephinite (a natural alloy of nickel and platinum), some platinum (slightly magnetic), magnetite, pyrrhotite, and in far less degree a number of other minerals. A German scientist—Plœcker—determined the relative magnetic attraction of a number of minerals, taking iron as 100,000. He found that magnetite was 40,227; hematite, crystallized, 533; massive, 134; limonite, 71; pyrite, 150. Many minerals only slightly magnetic become noticeably so on being subjected to high heat. On this property is based the success attending the use of the electro-magnetic separator in concentration of zinc and other ores.

WHERE rock is much decomposed—so much so that it cannot be drilled without much trouble from caving of loose ground into the hole—the ground may sometimes be successfully drilled by means of a bit auger. The bit is made like what is sometimes called a "swallow tail," one point being turned slightly to the right, the other to the left. The bit can be placed in an improvised brace similar to that used by carpenters, but more simple in design, being merely a rod of steel bent at right angles so as to form a crank. It is well to place a wooden handle on the crank before making the bends, as this will greatly facilitate the operation of the auger. When rock is so soft it cannot be bored by a device of this kind, it can be removed by picking and shoveling. Low nitro powder or black powder is strong enough for ground that requires to be bored with augers.

FLUX is material added to an ore charge to cause it to smelt readily, freeing the metal present. Quartz alone is practically infusible at a temperature which will melt all of the minerals with which it is associated. The quartz is acid, and a basic flux is required. In assay charges the addition of the basic flux sodium carbonate forms a suitable combination and the two substances fuse, forming silicate of soda, and gold will separate and unite with the particles of molten lead derived from the reduction of the litharge, which has also been added to the charge for this purpose.

AT copper smelters 20 pounds of copper in ore or matte is called a unit or 1% of the ore or matte by weight. The gross value of a unit is 20 pounds times the market price 1 pound of the metal. Thus, a 20% ore contains 20 units or 400 pounds of copper in 1 ton of 2000 pounds. With copper at 15 cents per pound, a unit is worth $3 and the ore is worth $60 per ton. This is gross or assay value, from which the smelters deduct the costs of shipment of the metal to New York, and also refining charges. In Arizona these charges generally amount to 3½ to 4 cents per pound in addition to smelting charges and deductions for moisture in the ore, and a small percentage sometimes deducted for mechanical losses in the slag.

AIR COMPRESSORS should be so arranged that the air taken into the compressing cylinders should have as low a temperature as possible, and a liberal supply of cold water should be run through the jackets. When air is compressed its temperature rises. If it were not for that fact the efficiency of compressors would be nearly 100%, but the air becomes heated, expands and exerts a certain amount of back pressure. As soon as the air leaves the compressor, passing to the receiver and pipe line, the temperature is lowered and a corresponding decrease in pressure takes place. If the air can conveniently be reheated near the point of use it will be again expanded with increase of pressure and corresponding increased efficiency.

THE "Stark process" is in successful operation in South Africa, on the Rand. The process, if it can be called such, consists in simply pumping water onto old dumps of cyanided tailings. These dumps are theoretically considered to contain all the essential elements to successful treatment. At first the amount of gold recovered was small, but the amount increased in time until now it constitutes a very substantial sum. The solutions as they come from the dump are run onto old mine cables and other scrap iron, when precipitation results. The entire process is apparently suggested by the leaching of dumps of copper ore. So successful have these attempts in this direction been that a floor is now prepared for the tailings by running a quantity of slimes into the tailings pond, as an impervious floor is an essential feature of the successful operation of the process. A similar scheme was adopted at a Mexican mine several months ago.

IN West Australian milling practice it has been found that the limit of economy in breaking rock for stamping in the various types of breakers has been reached when the pieces will pass a 2½-inch ring. In the batteries a 15-mesh screen is found to give the maximum economic result. The subsequent grinding in pans completes the communition of the ore, and this is arranged so as to produce an almost uniform product by regulating speed of the muller. At the upper rim of the pan is an outlet overflow. When run at a high speed—sixty revolutions per minute—the pan will produce several grades or sizes, but at slow speed—twelve or fifteen revolutions per minute—a stated size only is produced, which being comparatively fine rises, being forced to the surface by the sinking toward the bottom of the coarser material, the fine overflowing, the coarser in time being ground and rising to flow away. By this arrangement few slimes are produced and the desired size of particles can be obtained. The tube mill is employed when slimes are desired.

THE cost of putting down deep holes (15 to 20 feet) with churn drill must depend somewhat on the character of rock drilled, upon the drill itself and upon the industry of the men employed in the work. Three men should drill a 15 to 18-foot hole in one shift of ten hours. Their wages would be probably $2.50 to $3 each, or $7.50 to $9 for an 18-foot hole. In hard rock the progress would not be so fast, and in very hard rock proportionally less. If three holes can be drilled 18 feet deep on a suitable bench or in the side of an open cut, the holes 20 feet apart, and with a "burden" of 12 to 15 feet on the holes, after "springing" or chambering, these holes should break 800 to 1000 tons of rock, and under favorable conditions more. The cost for drilling alone under average conditions would be from 3 to 5 cents per ton of rock broken. A good drill for this kind of work is made by welding 1¼-inch drill steel onto each end of a 1½-inch pipe. The bit at one end should be a little smaller than at the other in order that the drill when reversed may "follow" readily in the hole already drilled. Novices at the work cannot be expected to operate a "jumper" or churn drill as well as those who are experienced, but it is easily learned.

Discovery and Development of the Homestake Mines of South Dakota.

NUMBER III.

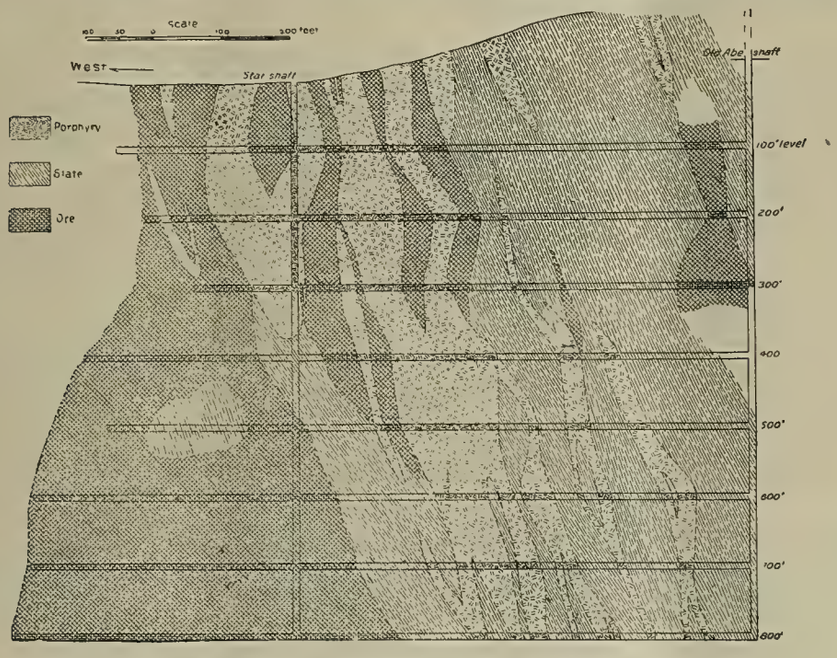
Written for the MINING AND SCIENTIFIC PRESS.

The methods of carrying on the work of mining in former days left many blocks of ore in the backs of stopes, which became too dangerous to work farther, and in some instances considerable amounts of ore were involved in caves which occurred. The management has introduced new systems of mining throughout in new ground, each method being particularly adapted to the physical conditions obtaining at that place. Robbing these old workings and recovering ore lost in caves has also become a feature of mining operations in these mines. Often under the old system mining was discontinued in a stope where the conditions became in any way disadvantageous. In each of these several cases the ore is now being recovered—not because there is a shortage of ore, but because it is not considered good business to leave ore in the mine which is accessible and which may still be extracted at a profit.

Where it is determined to recover ore from a cave or the back of an old stope which it was found unsafe to further attempt to mine, the ore is approached from a level below, a raise of two compartments being put up, timbered by square sets. At the top a substantial bulkhead is built to protect the workmen. A grizzly is put in on the floor of the set next below the top, consisting of several pieces of timber 12x12 inches and spaced 12 inches apart. These timbers are faced with old boiler plate to render them durable. The ore which it is desired to secure has usually settled on a filling of waste. A run is started by working into the broken mass with bars, or blasting with moderate amounts of powder. Often the run once started, as in the case of some of the open cuts, the broken ore continues to come as fast as it is drawn off into the cars from the chute at the foot of the raise, until it has either all been drawn out or the slope angle will not permit it to run farther. Occasionally after a brief run a large excavation is discovered, in the roof and walls of which the ore is still solid. This ore is then stoped in the usual manner, the precaution being first taken to fill the open stope with waste. Sometimes a run of ore is followed by a run of waste. This latter is sent below to fill a stope on some lower level. Later waste may be again followed by ore for a time where the ore, which is in most cases readily distinguished by its appearance from waste, is sent to the mill. Many thousands of tons of ore have been recovered in the manner above described.

In the Terra mine stoping without timbers was carried on for a long time. The method is applicable to veins of clean ore having hard walls and standing at an angle above 40°. A crosscut was run from the nearest shaft across the formation to the ore body and entirely across it. The method of attack is variable. In some instances a drift was run in the foot wall parallel with the ore body and about 50 feet from it, and the stope opened from the crosscut. At intervals of about 30 feet the drift was connected with the stope by short crosscuts All the rock broken on the first floor, about 7 to 8 feet high, was shoveled into cars and removed. Mining upward continued and only sufficient ore was drawn off through the crosscuts run from the main drift to give the miners room to reach the back. As the work progressed upward raises were carried up to allow access to the stope. Stoping was carried up as close to the next level above as was considered safe, and the excavation already made was now practically filled with broken ore, only enough having been drawn off as work proceeded to make room. As 13 cubic feet of ore in place fills 20 cubic feet when broken, about 40% of the ore broken had been removed, the remaining 60% being ready for removal to the mills. By this method a large tonnage of broken ore was always on hand in the event of a temporary suspension of mining operations. The stopes thus worked were from 30 to 50 feet in width. The ore remaining between the back of the stope and the level above was recovered later by caving.

The most interesting feature of modern mining methods at the Homestake is the extraction of large ore bodies, no matter at what angle they may lie, with a minimum amount of timber and contemporaneous filling. There are several methods in vogue, which vary somewhat with the existing conditions. In the early days of underground mining on this belt the square set was introduced, but the mistake was made of trusting the timber supports to keep up the tremendous weight of the ground. Outside of some massive limestones and tuffs in dry regions, there is, perhaps, no better standing ground for large masses of rock than that at the Homestake; but even this has its limits of self-support, and when stopes are carried with such great dimensions as were attempted there, collapse is eventually inevitable, and such proved to be the case in these mines. Stopes more than 100 feet in width, 150 to 200 feet long and 80 to 100 feet high, with no support to the roof and hanging wall other than the timbers of the square set, caved in several of the mines. In some, if not all, of these cases the disaster might have been averted by running down into the stopes the waste rock of the porphyry cap which was in most instances available. At the Deadwood mine, north of the Terra, thousands of tons of this rock were removed and trammed to one side, to strip the ore body beneath, in order that it might be mined by the open cut method.



Cross Section of Homestake Ore Bodies Through Old Abe Shaft.

The accompanying sketch, taken from "Contributions to the Geology of the Northern Black Hills of South Dakota," United States Geological Survey, shows the immense size of some of the ore bodies in the Homestake mine. On the 800 level the main ore body is over 400 feet wide and below that level is in places over 500 feet in width. Mining men acquainted with large veins, where the square-set method of timbering is followed, realize what an enormous amount of timber is required to support these great stopes. Where sets are placed with the posts in the form of a square, with 6 feet from center to center and 7½ feet high, and 12x12 timbers are used, the average amount of timber in each set, exclusive of the sills, sprags and blocking (which are always as necessary as the main members of the set), is about 275 feet board measure, or about 14 feet for each ton of ore extracted from the space which this set fills. With timbers at $20 per thousand, this means a first cost of 14 cents per ton of ore for the timber as it arrives at the mine. To this must be added the expense of framing, handling, and setting up in the mine, which increases the expense to 25 or 30 cents per ton of ore. A stope 100 feet square and 100 feet high would require, if timbered by square set system, after the manner above suggested, about 1,000,000 feet of timber which, to place in the mine, would cost, at 25 cents per ton of ore removed, about $20,000. If timbers of larger dimensions are used the cost increases rapidly.

It was this tremendous expense for timbers which stimulated the Homestake management and engineers to devise a method by means of which these large ore bodies could be safely extracted without loss and with a minimum expense for timbers. The result of the efforts in this direction was the introduction of an entirely new method of ore extraction and support to the stopes.

In one new system the main crosscut is driven from the nearest shaft to and entirely across the lode to the foot wall. A heading is then run along the foot wall, about 25 feet in width, and from this heading stopes are opened, 60 feet wide, with blocks of ore 60 feet wide intervening. Sills are laid in these stopes from foot toward the hanging wall, being advanced as fast as the work proceeds. On the sills the square sets are placed in the usual manner, and when stoping and timbering have advanced far enough, waste is run into the stope from some point above and the stope filled. As the work of ore extraction and timbering proceeds toward the hanging wall the filling is introduced into that portion of the stope adjoining the foot wall, following the stoping toward the hanging, the gangways being protected by heavy lagging. When a stope is completed from foot to hanging the pillar left on either side may be removed in like manner, the waste in the stope previously extracted being prevented from running into the new stope by lagging placed in the sides of the old stope timbers.

This system, although a marked improvement on former methods, and one which gave increased safety in mining, and also permitted the recovery of all the ore without undue risk, still required a vast amount of timber in its operation, and the management decided that further experimenting in the direction of economy was advisable. Accordingly various expedients were suggested and tried, resulting in the adoption of methods which are quite as safe as that above described while requiring only a small amount of timber as compared with the former methods. This new method was named the Homestake system, and is applicable to large stopes where the ground is fairly good, everywhere.

(TO BE CONTINUED.)

The Rational Design of Head Frames.

TO THE EDITOR:—Referring to Mr. Binckley's reply to my own communication published by you on June 17th, I desire to add a few words to elucidate two points raised in his letter.

Mr. Binckley states that, in the head frame designed by me for the Wildman mine, the dimensions of steel in the front column is apparently the same as in the main brace, an impression presumably caused by the small scale of the drawing. The main braces are made of two 15-inch I beams, and the counter-braces of two 12-inch channels, their object being solely to steady the former, as explained further on, and to act as anchors in case of overwinding.

It is true that the sheave bearings are bolted on to one side of uprights resting on a cross piece directly supported by the main braces, at their center, the bolts being figured out to stand in shearing the resulting strain of the cable tensions. The consequence of this arrangement was the possibility of laying a cap across the top of the main braces and above the sheaves, which was considered desirable in order to rig up an overhead traveler for handling them. There is no question, moreover, but that, when the center of the sheaves can be set as Mr. Binckley recommends it, in the middle plane of the braces, they are in a geometrically correct position for making up the strain diagrams; but in the Wildman frame the resultant of rope tensions is actually, if not singly, taken up by the main braces, just as in a Cornish pump, the thrust on the plungers is taken up by the main rod, or like the weight of a line shaft, is transmitted to a post by means of the supporting bracket; there is only, besides the longitudinal thrust on the main braces, a transverse strain which does not exist in the geometrical arrangement, and which is taken care of by the counter-braces.

I fully agree to the fact that Mr. Binckley's former article of 1899, like the subsequent one, made the principle involved so plain that any one could have made up such a design without difficulty. It was in the early summer of 1898 that John Ross, Jr., the manager of the Wildman Co., took up with the writer the question of the projected installations at their Emerson shaft, including not only the head frame, but also the annexed crushing plant and mill buildings. There was no intention of rushing the completion of definite plans, and the main lines subsequently followed up for the head gear had been agreed upon with a number of other points months before the final drawings were made.

I would say, in concluding what is not a controversy, that at no time did I have any desire of depriving Mr. Binckley of the deserved credit attached to his able treatment of this subject; no question is raised as to who first called the attention of your readers to that type of head frame. Mr. Binckley did it on two occasions at least, whereas I never con-

tributed a line to the matter, the cut of the Wildman frame appearing in an article from the pen of John Ross. I simply happened to submit a design involving a distribution of strains which I did not at that time consider a personal conception, but which I knew to be rational, and it is to be hoped for the sake of sound engineering that the present tendency towards deep mining, and consequently substantial head gears, will lead to the general adoption of frames designed upon the lines rightly advocated in Mr. Binckley's articles. A. E. CHODZKO.

The Treatment of Refractory Auriferous Sulphides at the Cassilis Mine, Victoria, Australia.*

NUMBER II.—CONCLUDED.

Written by FRANCIS B. STEPHENS.

With the adoption of classifiers no occasion was found for use of Raff wheels, which were thrown out. At the end of the tables an inner sliding box was arranged in the usual concentrates box for the purpose of catching the galena concentrates. These concentrates contained a quantity of arsenical pyrites, and were daily reconcentrated on a separate table reserved for this purpose, and three products were made.

Of these the heads, containing 40% of lead, went to the grinding pans; the middlings, containing 15% to 20% of lead, 15% to 20% of arsenic, and eight ounces of gold per ton, were shipped direct to the smelter; and the thirds went back to the ordinary concentrates for chlorination. Smelters, by the way, paid for gold, silver, and lead, but deducted 1s per unit for arsenic. The galena headings were ground in a Berdan pan with mercury and a little cyanide for a period of twelve hours or less, and the ground pulp when removed from the pans was stirred in a tub and allowed to settle, when the top sludge was removed, put into jute bags to drain, and shipped to smelters.

Settlings at the bottom of the tub, after removal of the bulk of the mercury and amalgam, were returned to the next charge, and in this way the mercury loss was kept at a minimum, averaging for all operations at the mill from .75 to 1.05 ounce per ton crushed. The lead sludge from the grinding carried about 15 ounces gold, 40% lead and 10% arsenic when shipped, the gold value before grinding being sometimes as high as 60 ounces. The stamps were run at 96–100 drops per minute with a 6–7-inch drop.

Any more elaborate system of concentration would not, under the peculiar circumstances, have proved commercially advantageous. When the plant was run without hydraulic classifiers great losses of concentrates took place, to test which a trial of ore running 28 dwts. was made.

The stream of pulp was divided, one-half being concentrated without previous classification and the remainder being run through classifiers first, with the result that tailings in the former case went 7 dwts. and in the latter case 3 dwts. The capacity of the tables was increased fully 25% by the use of classifiers.

The sands freed from concentrates by magnetic concentration proved barren, so that this was an ideal ore for a complete system of classification.

In due course the canvas slime tables were abandoned, as the values saved did not pay for the labor, and the slimes were settled in a series of terraced dams which assayed as follows:

Top dam	4.5	dwts.	of gold	per ton
Middle dam	4.5	"	"	"
Bottom dam	5.0	"	"	"
Overflow	12.0	"	"	"

The amount of solids overflowing amounted to only 1% of the amount crushed. No attempt was made to treat the slimes separately, as the quantity accumulated was not sufficient to warrant the addition to plant.

CHLORINATION TREATMENT.—As it was usual to make from 15% to 20% of concentrates running from three to four ounces of gold and containing over 50% of the total gold value of the ore crushed, the chlorination work had to be run as cheaply as possible. The following is the analysis of a sample of concentrates, including galena, and representing the average over a week, although the variation was very great for all the constituents:

	Per Cent.
Lead	4.48
Zinc	5.26
Iron	31.56
Arsenic	15.16
Sulphur	31.53
Unestimated	11.91
Total	100.00

The writer in taking charge found that the short hand-rabbled reverberatories were quite unsuited for the work, on account of the concentrates fusing too easily. As the galena could not all be separated, some form of mechanical furnace was absolutely necessary. Chlorine solutions generated from bleaching powder and sulphuric acid were used in 10-ton open wooden vats, and after comparative trials against gas this method was retained as offering many advantages, being actually cheaper for this ore, while the extractions were the same for both.

Two Edwards' mechanical furnaces with 60-foot hearths were installed with excellent results. One man per shift of eight hours attended to all the work of two furnaces with a weekly capacity of 30 to 35 tons each. The furnace man charged the hoppers from the battery hoppers, stoked his two furnaces and looked after the engine and dynamo for lighting the works. The fumes were led into a brick flue 300 feet long and 5 feet by 4 feet inside, with a 40-foot iron stack 2½ feet in diameter.

The height of the top of the stack above the hearths of the furnaces was 70 feet, and small dust chambers were built between the ends of the furnaces and the flue. The iron stack did not suffer at all, and it acted as an excellent arsenic condenser. It was necessary to clean the whole length of the flue every three months, about thirty tons of deposit being obtained.

The flue dust for the first 100 feet consisted of partially roasted concentrates and arsenic soot assaying about three ounces of gold per ton, or about the same value as the concentrates roasted. The last 200 feet of flue contained arsenic soot comparatively free from concentrates, and assayed at the rate of 7½ dwts. The arsenic at the base of the iron stack had to be cleared out weekly, and it was a matter of serious consideration what to do with this material in a mountainous rocky district.

Finally it was buried with the residues of the chlorination works. All attempts to rework the rich flue dust with the raw concentrates for reroasting failed, as the extractions fell off so greatly, so this material was placed in heaps to weather and afterwards roasted and treated by itself.

Just before the finish of the roast 1% to 1½% of salt was added to the ordinary concentrates in order to obtain a sweet roast. No evidence of loss of gold by volatilization could be obtained, although on one occasion, when roasting some concentrates containing a heavy amount of orpiment, the teeth of the last rabble were coated $\frac{1}{16}$ inch deep with crystalline gold. Similar occurrences have been noted at Kalgoorlie, I believe, but I have heard of no explanation why white-hot cast iron should have gold deposited on it, nor can I suggest one.

The roasted ore was discharged into a push conveyor carrying the ore to a steel bucket elevator, which took it to a cooling bin over the treatment vats. Dry wood was used as fuel; any green sticks getting in generally had the effect of throwing back the charge to magnetic oxide. Badly roasted ore set hard in the vats, while well roasted ore did not. The ore in the hand-rabbled furnaces always roasted black, while in the mechanical furnaces it roasted cocoa color, but never bright red. The brighter the color obtained on roasting the better the roast, although a magnet failed to show any difference. Practically no zinc was sent into the flue, the heat not being high enough, being mostly in the roasted ore as sulphate or basic sulphate.

During treatment the zinc was almost all leached out of the vats by the sulphuric acid, but the amount of zinc seemed to have no influence on the extractions other than to prolong the extraction period, owing to the sand in the vats packing as the zinc leached out. Vats holding ten tons and made of 3-inch Kauri pine staves were used.

An ordinary graded pebble and sand bottom was used, and was replaced when it showed signs of clogging. Strange as it may seem, the filter bottom and the lead solution pipes used to get clogged with magnesium sulphate, but a little hot water free from sulphuric acid soon cleared this out. The chlorine solutions run on had a strength of .09% to 1.2% of chlorine and from 0.5% to 1% of sulphuric acid over and above the quantity required to combine with the bleaching powder. In this way many deleterious compounds were leached out or rendered harmless, most of the copper present being leached out in the first solution, leaving the ore in a good condition for the next solution.

The first solution usually had all its chlorine used up, but on well-roasted ore the solution ran off showing chlorine freely. The solutions were not allowed to remain long in contact with the ore, as otherwise the chlorine became used up and the gold already dissolved was precipitated in the vat. Solutions were run on for six days, or till the off-flowing solutions failed to react well for gold. The solutions were allowed to settle in an intermediate vat before precipitation.

This vat was fitted with plugs every 6 inches for drawing off small portions for assay, and an extra check on the amount of gold due at the cleanup was obtained. Ferrous sulphate was used as a precipitant, and was made from old battery screens. A considerable amount of basic iron sulphate, etc., settled in the precipitating vats and at cleanup time was taken into solution with the sulphuric acid. Copper gave very little trouble, but it seldom went over 1% or 2% in the concentrates. Owing to the use of such weak solutions, not much chlorine passed into the atmosphere. Less chlorine was consumed than if dry gas had been used on this ore.

An extraction of about 85% was obtained on well-roasted ore, the loss amounting to 1 to 2 dwts. per ton crushed. Shipping to the smelters and treatment charges amounted to £6 per ton, while our costs, plus the value of gold left in, did not amount to half that. The drawback to the use of 10-ton vats was the fact that a little carelessness on the part of a furnaceman spoilt the extraction of a whole vat. The ore at the furnace discharge was tested every five or ten minutes, and none but very reliable men could be employed on this work.

Numerous experiments were carried out to try and better the extractions, but with no success, although they led to a steady decrease in the cost of chemicals. Fine grinding after roasting gave no better results. Dry gas gave the same extractions as chlorine solutions, but the method was more expensive and decidedly more troublesome to work. The cream-colored mud which settled in the intermediate solution vats before precipitation was of a very complex nature, consisting largely of basic sulphate of iron and up to 20% of manganese and arsenic.

On treating this mud with sulphuric acid it all went into solution and left a small amount of black residue behind. This residue turned out to be gold, but was quite insoluble in chlorine water or cyanide, even on long standing. Doubtless this was due to the chemical condition of the gold precipitated in the treatment vat if solutions were allowed to stand long in contact with the roasted ores, as no lengthening of the time of treatment on a vat of this description would give a good extraction.

To test this a solution of gold chloride was poured on a sample of well-roasted ore and allowed to stand all night. In the morning all the gold was precipitated, and could not be redissolved by chlorine water, and yet this same ore gave good extractions if the first solutions were run off quickly. At one time solutions were only run on on two shifts, but after the above facts were proved three shifts were started with very beneficial results. What the chemical condition of this precipitated gold was the writer is unable to state, as sufficient was never collected to determine this.

TREATMENT OF TAILINGS.—Cyanide works were erected for the treatment of accumulated tailings; but these leached very badly, owing to the large percentage of talc and mica scales and the nature of the slimes. The slimes running high in concentrates settled in large quantities with the coarse sands in spite of the dams being kept narrow—most of the tailings were made before the introduction of classifiers—and these slimes percolated very badly and gave a poor extraction even with agitation.

The sands could be separated in layers like leather and had exactly the appearance of mica slates. A trial was made of direct filling from the mill, using a Butters' distributor, but with very unsatisfactory results, owing to the amount of high-value slimes that had to be run away to get a leachable product. The following analysis of a vat settled in this manner shows how unsuited these tailings were for a direct leaching process:

Retained by 40-mesh, 14.4% at 4.00 dwts. per ton.
" " 60-mesh, 20.7% at 2.75 dwts. per ton.
" " 80-mesh, 9.1% at 2.00 dwts. per ton.
" " 100-mesh, 20.7% at 2.25 dwts. per ton.
Passed 100-mesh, 35.1% at 6.25 dwts. per ton.

Consequently a great amount of preparatory work in the way of drying and mixing had to be done in the dams to get a product that would leach. An ordinary agricultural scorifier and an earth scoop were used for this work, which could only be carried on in dry weather.

The sands, after filling, were water-washed for eight to twelve hours to remove magnesium sulphate, which was present in large quantities. The wash water coming off showed no free sulphuric acid and not a trace of iron salts. Considering the large quantity of iron and arsenical pyrites in the tailings, this was at least remarkable, and that the pyrites had oxidized was shown by the large amount of magnesium sulphate. About seventy pounds of caustic soda was used on a 90-ton vat and the cyanide solutions were made up to .25% of KCy.

Caustic soda, unfortunately, dissolved arsenic compounds readily, especially orpiment and hydrated arseniate of iron, which were present in considerable amount, and the solutions entering the zinc boxes carried .5% of arsenic, causing a heavy consumption of zinc.

To obviate this difficulty, solutions were not allowed to remain in contact with the sands and matters improved very much.

Solutions which ran off quite clear on standing became quite milky with magnesia hydrate, and this precipitate settled thickly on the zinc and spoiled its efficiency. Extractions ranged between 60% and 65% and the consumption of cyanide kept at the moderate amount of seventy-five pounds. A treatment of seventy-two hours was given, but a longer treatment gave no better extractions. The use of an oxidizing agent in experiments increased the extractions 10%. The water supply destroyed permanganate readily; organic matter in the water may have accounted for this, as the water came from peat bogs. If the ore were leached with distilled water, a heavy consumption of permanganate followed on the magnesium sulphate, which seems rather strange.

ASSAYING CYANIDE SOLUTIONS.—The following method of assaying cyanide solutions was worked out by our assayer, A. M. Henderson, and used with success: The solutions to be assayed are electrolyzed for a period of four hours, the gold being precipitated on a cathode of lead foil, the anode consisting of a wrought iron rod. The formation of Prussian blue on the anode is prevented by the addition of an excess of ammonia, and the necessary circulation of

*Trans. Inst. Min. and Met.

the solution is caused by the liberated gas bubbles and the peculiar shape of the cathode.

The precipitation of gold is very complete. On solutions assaying 10 to 15 dwts. of gold per ton and containing .03% to .25% of cyanide the value is reduced to below 3 grs. in four hours with the necessary current density. As compared with evaporation, the results are more consistent. In practice 10 assay tons—212 c.c.—of solution are taken in a tall beaker and 12 to 15 c.c. of strong ammonia added.

The lead cathode consists of a cylinder of lead foil 2½ inches high and 1 inch in diameter, with three V-shaped notches cut in the lower rim, a lead strip being attached at the top with which to make connection. The lead foil cylinder should be covered to a depth of about ½ inch, and a 6-inch nail is used as an anode. The disengaged gas bubbles cause an upward current in the solution inside the cylinder and down round the outside and through the V notches in the bottom.

It is usual to make from fourteen to twenty assays at one time, all joined in series between the terminals of 110-volt lighting mains. With twenty assays in series no extra resistance is necessary, but with a lesser number than fourteen incandescent lamps are inserted.

The current used is from .06 to 1.2 ampere, the fouler the solution the higher the current density that can be safely used. The gold comes down as a bright yellow deposit, and when precipitation is complete the cathode is washed in water, dried, rolled up, scorified with the addition of some test lead, and cupelled.

COSTS.—The following table shows the mining, milling, chlorinating, cyaniding and smelting costs, on a weekly output of 270 tons milled and mined, 54 tons of concentrates chlorinated, 300 tons of tailings cyanided from the dams, and 4 tons of galena shipped for smelting:

Mining—Average cost of mining, developing, and transporting 1 ton of ore, 15s. 3d.

Milling—Tons crushed 270, wages 2s. 2.2d., fuel 11.2d., stores 6.6d., general charges 1s. 1.8d., cost per ton crushed 4s. 10.8d.

Roasting—Tons roasted 54, wages 3s. 11.3d., fuel 4s. 5.3d., repairs 2d., general charges 1s. 10.3d—cost per ton roasted 10s. 4.9d.

Chlorinating—Tons treated 54, wages 2s. 9.5d., chemicals 4s. 10.2d., general charges 1s. 7.3d—cost per ton treated 9s. 3d.

Cyaniding—Tons treated 300, wages 1s. 9.8d., chemicals, etc. 10d., fuel 4.2d.—cost per ton treated 3s.

SUMMARY.

	Per Ton Crushed. £.	s.	d.
Mining, developing and transporting	0	15	3.0
Milling and concentrating	0	4	10.8
Chlorinating and roasting	0	3	11.2
Cyaniding	0	3	0.0
Shipment and smelting charges	0	1	9.0
Total costs	£1	8	10.0

These costs do not include directors' fees and Melbourne office expenses. Owing to heavy freight charges the following costs are high:

Bleaching powder (27% to 30% available chlorine) cost £18 per ton.

Chamber sulphuric acid cost £11 per ton.

Engine wood cost 14s. per cord of 125 cubic feet.

Furnace wood cost 16s. per cord of 125 cubic feet.

Explosives cost as follows:

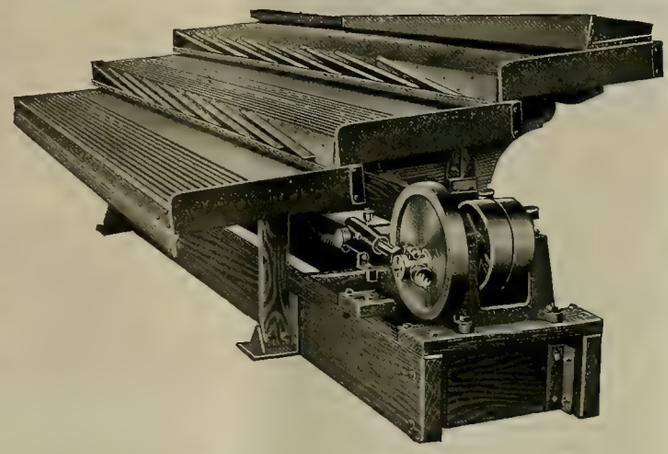
	Per Case on Mine. £.	s.	d.
Gelignite	3	2	6
Gelatine dynamite	3	12	6
Blasting gelatine	4	2	6

The cost of erecting this plant, including office buildings, housings, etc., but exclusive of cost of air compressor, was about £20,000, and was all paid for out of the profits as the work proceeded, showing that excellent profits could be made by ordinary milling methods, from what had been considered by many to be only a smelting proposition.

NOTE.—The chlorination process, as practiced at the Cassilis Company's works, and which is referred to by the writer above, is as follows: "The chlorination plant consists of seven circular treatment tanks, 12 feet in diameter and 3 feet 6 inches deep, above the filter floor; four precipitating tanks, each 8 feet diameter and 4 feet depth; two storage tanks, each 5x4 feet. The chlorine is generated by the action of sulphuric acid on bleaching powder. At these works 220 pounds of chloride of lime (bleaching powder) are dissolved in 8 tons of water, and a solution of 1% sulphuric acid is prepared. These two solutions are run upon the ore simultaneously through a V-pipe, which is connected with the solution tanks. The strength of the chlorine solution thus formed is about 0.15%. The time of leaching is about seven days, generally. The chlorine solution, after passing through the charge of ore, is run to two settling tanks, from which the solution, after being allowed to settle, is drawn off into precipitating tanks, in which the gold is precipitated by means of an acid solution of ferrous sulphate. This is made at the works by treating iron in a boiler with sulphuric acid. The ferrous sulphate solution is poured into the precipitating vat by the bucketful, until it is found to be in excess by testing with gold chloride. After thoroughly stirring, the precipitate is allowed to settle for 48 hours, when the clear liquor is drawn off by means of a rubber hose connected at one end with a pipe, which passes into the tank 3 inches above its bottom, and at the other end to a dish which floats on the surface of the liquid. By this ingenious means all of the liquor can be drawn off without disturbing the precipitate on the bottom of the tank. When it has run down to the level of the pipe, the vat is tilted slightly and the remaining liquor with the gold removed by means of buckets into small tubs. Here it is again allowed to settle and the clear liquid drawn off. The precipitate is then digested in sulphuric acid, washed, removed to a filter and allowed to drain, and is finally washed into an iron pot. When dry, the precipitate is heated to redness and niter added, after which it is smelted with borax. The precipitate contains generally from 70% to 80% gold, and the gold runs 980 to 990 fine. It is said the extraction of the gold values from the concentrates is from 85% to 87% of their assay value. This process is a modification of the Muncktell process.

The Bartlett Simplex Concentrator.

Herewith is illustrated the new Bartlett simplex concentrating table now being manufactured by the Colorado Iron Works Co. of Denver, Colo. The building of the old Bartlett table has been discontinued. The simplex is less than one-half the weight, has one-third more capacity and is one-third less in price,



Bartlett Simplex Concentrating Table.

and one-half less power is required than on the old-style Bartlett table. It is set up and vibrates on four broad hickory strips, to give the table resiliency and quick action. Each deck is designed to be an independent concentrator and each can be removed in five minutes by taking out three hinge bolts. Its construction is of the armored wood pattern, containing no mortises or tenons. It is put together with bolts and can be taken apart into pieces which weigh 100 pounds or less.

Each deck is covered with a single piece of solid rubber, riffled, the riffles being molded on when the plate is made at the rubber factory. This special molded rubber top is covered by United States patents, issued Jan. 27, 1903, and others now pending. Each top or deck is provided with thirteen riffles, 1 inch apart, ½ inch high at the feed end, tapering to the extreme discharge end. These riffles are banked on the lower edge of the deck, having a smooth blank space 9 inches wide where the ore discharges. This blank space is intended to allow fine ore and slimes opportunity to settle and stratify. The manufacturers point out that the ore travels faster on the first deck than on the second, and slower on the third than on the second, and claim that, as the concentrates are largely removed on the first deck, less movement is required for the second and third, thus giving the material more time to settle and stratify. The wash water pipes are independent of the table. They discharge into open launders, hence are not easily clogged by dirt in the wash water.

The simplex weighs 900 pounds. Its builders state that it requires only ½ actual H. P. to operate. They also claim that three separate classes of concentrates can be made on the table and that the capacity is very large. It is claimed that this table saves slimes so closely that no after treatment is required. Complete information and literature may be had by addressing the manufacturers.

The First Ingot of Mexican Tin.

Some 200 or 300 years ago the Spaniards worked deposits of float or placer tin at a point about 40 miles from Aguas Calientes, Mexico, says the Engineering News. Last year W. A. Pratt, who has been an assayer at Aguas Calientes for several years, and his associates discovered a tin vein from which the float tin had evidently come. On Feb. 23 of this year an ingot of tin weighing fifty pounds was smelted from the ore of this vein. This ingot is believed to be the first ever cast in Mexico. The vein is said to be about 5 feet wide, containing stringers of tin, and can be traced for a mile. The vein is said to run from 2½% to 4% tin, which compares well with Cornwall ore, most of which runs less than 1%. There is so small an amount of iron (1%) in this vein that the ore can be economically concentrated and smelted. Mr. Pratt has organized the Consolidated Tin Mining & Smelting Co. of Mexico, and he writes us that shaft sinking and tunneling on the vein are now under way. The address of the company is Aguas Calientes, Mexico.

Vertical Shaft Sinking on the Rand.*

In the discussion of the paper by H. F. Roche, on "Vertical Shaft Sinking on the Witwatersrand," in the Journal of the Chemical, Metallurgical and Mining Society of South Africa, an abstract of which appeared herein in the issue of May 6, E. M. Weston said:

There are one or two matters in Mr. Roche's interesting paper I should like to have made clearer. He considers that any advantage buckets or kibbles may have over skips for sinking are far outweighed by the three advantages of greater safety, quicker hauling and better baling facilities claimed for skips. In his opinion they outweigh the time lost in cleaning down 50 or 60 feet of extra shaft timbering after each firing, and of fixing and adjusting the false sets and guides necessary to carry the skips to the bottom of shaft (an operation taking time and care), in lowering and fixing and afterwards taking out and hoisting before fixing again. Nor does he consider that the possibility of swinging the bucket about the shaft to favorable positions for loading, nor the greater immunity of the timbers to damage, does anything like balance the advantages he claims for skips. Would Mr. Roche be kind enough to supplement his paper by giving figures showing actual time of loading, hauling and tipping skip from a given depth and their capacity, as against corresponding figures for buckets at other shafts like the Cinderella Deep and Western shaft of Village Deep. Twenty feet a month is such a serious difference between the two methods, that the question as to whether this would hold true in all shafts and under all conditions cannot be too thoroughly inquired into. Clay may not always be the most suitable material for surrounding the shaft near the surface, as the nature of the ground may call for the more solid support afforded by concrete, masonry, brickwork, or iron tubing. Mr. Roche's reason for preferring 3-inch or 3½-inch machines to smaller machines in shaft sinking is not convincing. In the first place he ignores the fact that the ground to be sunk through may not be hard, and that the long holes may not be suitable owing to the way the ground breaks. I hold, however, that it is a fallacy to believe that small machines, say 2¾-inch diameter, will not bore as quickly in hard ground as big ones will. They will always do so if they are not expected to drive jumpers with bits not suitable to their size. Much trouble has been caused, and small machines often given a poor chance of competing with the larger sizes, by either giving them jumpers too nearly resembling hand steel and capable of boring only short holes, or giving them identical steel to that of big machines to bore a 7-foot hole. With jumpers fitted with bits of a suitable size a 2¾-inch machine should drill 6 to 7 feet deep in the same time as a large machine. Taking the difference of size of bits at ½ inch, though it can often be made ⅝ inch, a set of steel for a big machine to bore about a 7-foot hole would have the following sizes: Short starter, say about 18 inches long, bit 3¼ inch; starter 30 inches long, 3-inch bit; second, 4 feet 6 inches long, 2½-inch bit; long second, a short chisel, 6 feet 6 inches long, 2-inch diameter; chisel of 1¼-inch diameter, octagon steel, 8 feet long, bit 1½ inch to 1¾ inch. The big machine having a "run out" of feed screw of about 2 feet. If a 2¾-inch machine were to be used for sinking it should be provided with a set of jumpers of, say, short starter about 18 inches long, bit 2⅜-inch diameter; long starter 3 feet long, bit 2⅜-inch diameter; second, 4 feet 6 inches long, 2-inch bit; short chisel of 1½ inch, octagon steel, 6 feet long, 1⅝-inch bit; long chisel, 7 feet 6 inches of 1-inch diameter, octagon steel, with 1¼-inch bit. These 2¾-inch machines have only 18 inches run out of feed screw, and so the bits are required to do less boring before being taken out, and can be made of closer gauge than the big machine jumpers which have to bore 24 inches.

It will be seen that the 2¾-inch machine is all the time boring with a bit a size smaller than that of a big machine, and can thus bore as fast in even hard rock. By finishing up with longer chisels of ¼-inch steel, an even longer hole can be bored. I have used them successfully in stoping. The advantage that these machines would have over big machines in sinking would be as follows: A 2¾-inch Ingersoll weighs 180 pounds, as against 280 to 290 pounds of a big machine, and takes up about half as much room in skip or bucket. They are thus very much more quickly handled, lowered, raised, set up and taken down. Nor do they cause so much stress on the bar, arm or clamp. They are more easily and quickly moved for holes and take up so much less room in shaft that, as is often the case, twelve big machines would be objected to at the bottom of a shaft as taking up too much room when lowered; twelve of these machines

*Trans. Jour. Chem. Met. & Min. Soc., S. A.

would cause no trouble at all. They should certainly be able to compete with the usual eight big machines. Their jumpers are much lighter and the weight to be lowered would be about the same in both cases, and being so much more easily handled, should be set up in the same time and bore out the shaft much quicker to a depth of 6 or 7 feet.

This brings us to the question, What is the most economical depth of hole for use in sinking? This must, of course, depend on the hardness of the ground, the way it breaks, whether it sets and cracks much after breaking, and the class of machines available. Other things being equal, long holes are always economical to bore, because it is the pitching and starting of the hole and the boring of the first 2 feet that takes up the greatest proportion of time, so the greater the ratio, the part of the hole that is bored with smaller bits bears to the first 2 feet, the quicker and the more economical the work. I am, however, surprised at the method Mr. Roche says was successful at the Village Deep. To bore 10-foot cut holes, to charge them fully, and yet to be able to break the first 4 feet must be extravagant in explosives, but what, as having had some experience in rock drilling, I cannot understand is that the plan of cleaning out and firing the stumps of the holes was at all successful. I have always found such holes most difficult to clean out and in some ground absolutely impossible. The fine rock will pack and set solid in them and larger pieces wedge themselves in the holes and their radiating cracks, so that it is impossible to blow them out or scrape them out. When cleaned out, such holes are too big to fire with economy, as there is no proper contact between the explosive and the solid ground. In any case, I should think the task of looking for twenty-four old holes and cleaning them out was, apart from the danger, one taking too much time and trouble to be successful. If, however, such long holes can be effectively fired, big machines should have the advantage over smaller ones. I should have thought that the plan of drilling a relieving cut with holes 5 feet long, and then either firing everything together (when the cut should come out clean), or half filling up the long holes, when bored, with clay or sand, and firing the relieving cut and the top halves of the other holes first, and the bottom cut holes and the rest of the other holes after cleaning, would have been much more economical in explosives, and much quicker and easier. I should think, however, that the speediest plan of sinking in any given shaft would be determined by first finding the maximum number of large or small machines that could be worked conveniently in it and decide which to use, when by the experiment the maximum depth of hole was found, that would, while keeping the shaft to its proper dimensions, come, bringing a clean cut with one charging and firing. The trouble of cleaning and firing twice should render a longer hole less effective, while a shorter one would be uneconomical for the reasons already given.

(TO BE CONTINUED.)

Drainage of a Rapid Transit Railroad Under a River.

One important engineering problem in the building of the New York rapid transit subway was the construction of the two tunnels, or tubes, under the Harlem river. These two tubes, through which the subway trains are to run regularly, were constructed on a new engineering principle, having been built of concrete above the ground, and then sunk to the bottom of the river, instead of having been forced through the mud under the river bottom, as had been done in such work heretofore. These twin tubes are 641 feet in length and are 16 feet in diameter, the top of the tunnel being 20 feet below the low water mark. Before the tubes were put in place, the engineering department of the subway contractors devised a system for the drainage of the seepage, or the water percolating through the walls of the tubes, and also in case of emergency arising from the sudden inrush of water in the event of the breaking of a water main. The drainage and pumping system adopted, and the precautions taken to meet the possible conditions, are portrayed herewith.

Fig. 1 shows a sectional view of the tunnel looking southwest, and showing the arrangement of the pumps which are in position in both of the tubes at the junction of the subway and the mouth of the tunnel at Harlem river. The pumps adopted for this service were specially designed and built by the

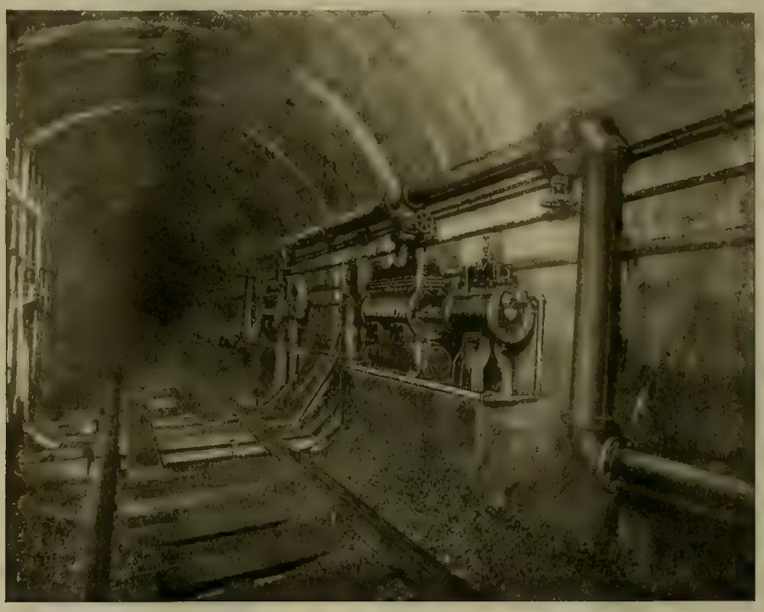


Fig. 2.

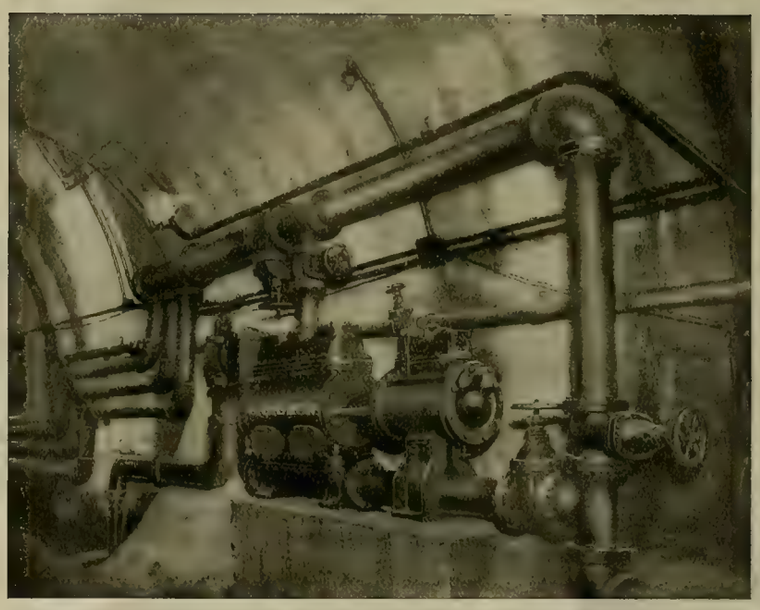

Fig. 3.

A. S. Cameron Steam Pump Works, whose general offices and works are at the foot of East Twenty-third street, New York. A longitudinal arrangement of the piping and connections for the pumps is shown on the right hand side of this illustration.

Fig. 2 shows two of the pumps in position on concrete foundations, with the arrangement of piping and connections. Four of these 12x12x18 pumps were installed, each having separate air lines to the compressor plant, ¾ of a mile away and above ground. The pumps are controlled automatically by separate floats located in the tunnel. The automatic float for one of the pumps is shown in the illustration along the wall on the left hand side. The other pump, in the distance, has its automatic float nearer the floor and attached to the pump. An air reservoir 16 inches in diameter by 36 inches long is arranged in the air pipe line at the throttle of each pump. The suction piping is also shown extending into the sump, the top of which is protected by iron gratings.

Fig. 3 depicts the outside construction of the pumps. The water valves are set in removable valve decks, allowing them to be easily removed with minimum time cost. The suction valves are placed under the water cylinder, and the discharge valves are shown above the water cylinder.

Each of the pumps are separately and independently connected and are also designed with the suction and delivery flanges looking fore and aft, permitting the arrangement of the suction pipes as shown, with the pipes running under the "air end," and the foot under the air end made in two parts, straddling the 6-inch suction pipe, permitting the piping to be readily removed.

Each of these pumps is capable of delivering 600 gallons of water per minute while running at a normal speed, with an air pressure at the throttle of about seventy pounds per square inch, and a total lift of 70 feet.

These pumps have already been severely tested owing to the discovery

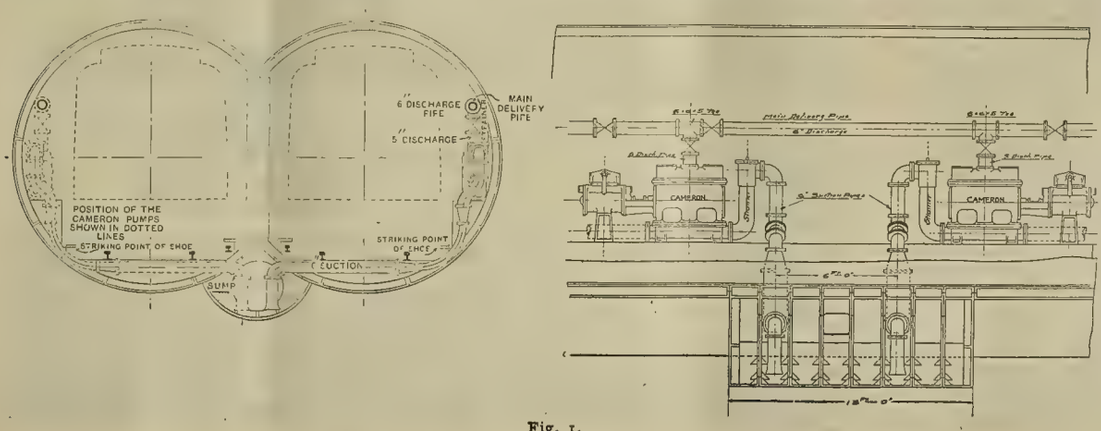

Fig. 1.

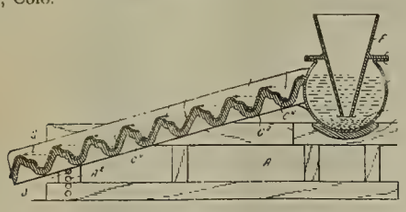
of water in the tunnel some time ago, when temporary piping and connections were hurriedly made and the pumps were pressed into use at short notice, being in operation day and night, and performing good service, the inflow of water being entirely taken care of and causing but a slight interruption in the completion of the work.

Mining and Metallurgical Patents.

PATENTS ISSUED JUNE 20, 1905.

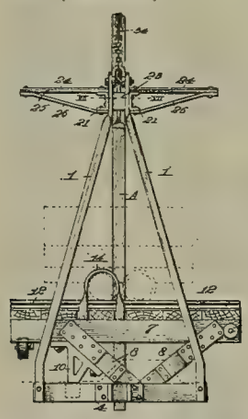
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PLACER MACHINE.—No. 792,111; D. T. Barry, Denver, Colo.



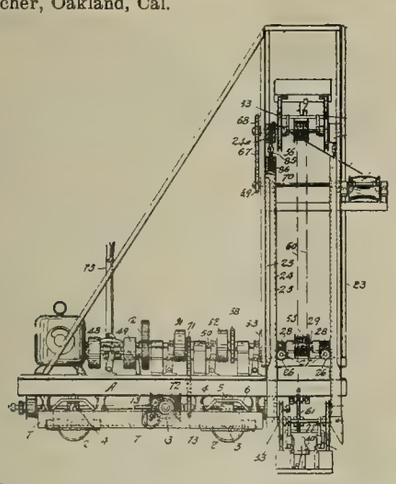
In machine of class described, combination of suitable support having curved seat, receptacle engaging seat, engaging portion being curved to conform to curve of seat, sluice rigidly connected with receptacle at suitable point above bottom, sluice being suitably inclined and having series of valleys and removable amalgamating plates mounted on bottom of sluice and made to conform to shape of bottom, bottom of each valley being comparatively narrow and shaped to form eddy as pulp falls thereinto, each plate being provided with ledge located between top and bottom of valley, and suitable means for supporting sluice whereby inclination may be regulated at will.

MINE CAGE.—No. 792,330; J. Herzler, H. Henninger and W. Fenner, Belleville, Ill.



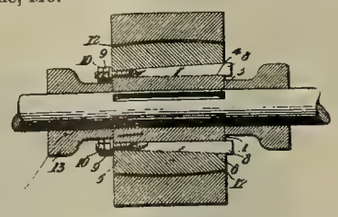
In mine cage, combination of bottom frame, shaft journaled in frame, platform, rockers mounted on shaft, inclined legs secured to rockers and tiltingly supporting platform, chairs secured to platform and to rear of rearmost platform legs and normally resting with lower end on bottom frame, and means for tilting forward end of platform.

EXCAVATING APPARATUS.—No. 792,699; W. H. Fulcher, Oakland, Cal.



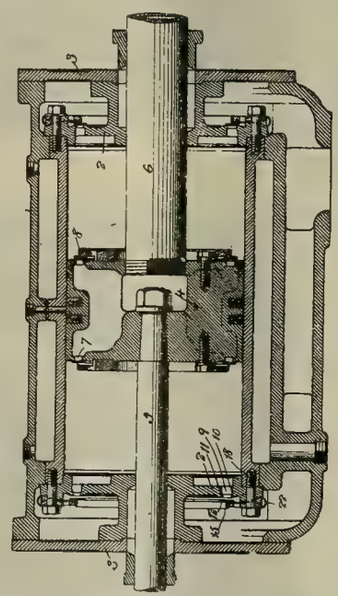
Excavator comprising wheeled or table frame, superposed frame or table mounted thereon, pair of vertical spaced guides at each side one end portion of superposed frame, vertical spuds mounted to slide in guides, means for moving spuds vertically, pulleys journaled near top and bottom of spuds, and endless chain of excavators passing around pulleys in direction at right angles to line of travel of wheeled bearing frame.

CRUSHING ROLL.—No. 792,733; O. H. Schoenherr, Carterville, Mo.



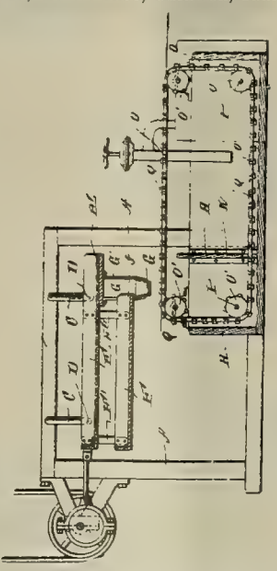
Crushing roll comprising polygonal hub, shell surrounding hub and having its inner face concaved longitudinally, segmental core sections interposed between hub and shell and extending at opposite sides of middle of hub, core sections having flat inner faces fitting respective flat faces of hub and longitudinal convexed outer faces corresponding to longitudinal concaved inner face of shell, each core section capable of radial movement independently of hub and shell, adjacent faces of hub and core sections having open-ended registering keyways, tapered keys driven into keyways and having smaller ends threaded and projected externally of hub, and nuts fitted to threaded ends of keys.

COMPRESSOR.—No. 792,788; W. Prellwitz, Easton, Pa.



Cylinder head having annular passage therethrough, annular valve therefor comprising ring portion and flange, and annular plate secured to head and spaced therefrom, inner wall of plate engaging outer wall of flange, forming guide for valve and limiting outward movement.

APPARATUS FOR SAVING PRECIOUS VALUES IN SOILS.—No. 792,617; B. W. Rice, Caldwell, Idaho.

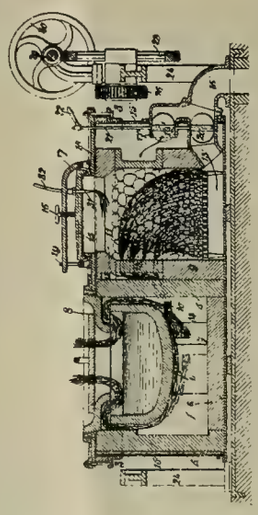


Apparatus for saving metallic values from sand, gravel, etc., comprising shaking screen, trough supported by arms secured to screen, screen box, bars supported by screen and positioned underneath exit end of trough, tank adapted to contain water and oil and positioned underneath screen box, sprocket wheels mounted within and upon upper edge of tank, sprocket chain traveling about wheels, cross pieces secured at intervals to links of chain and projecting laterally from sides of chain and adapted to travel adjacent to bottom of tank its entire length, and gate positioned within tank and underneath which cross pieces upon chain are adapted to travel.

PROCESS OF HARDENING AND TEMPERING COPPER.—No. 792,070; C. R. Plumer, Seattle, Wash.

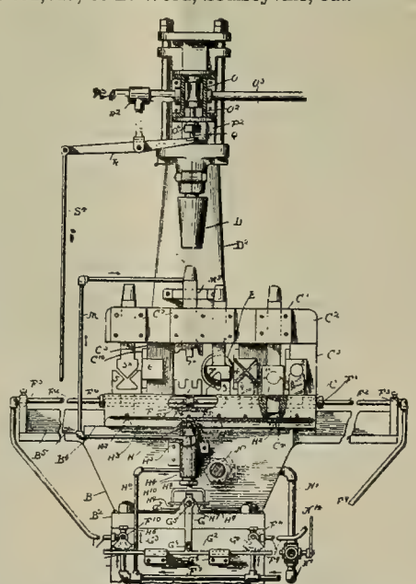
The herein described process of hardening copper or alloys of copper, comprising subjecting copper or alloys of copper to high temperature and while in heated condition subjecting same to action of sulphate of copper (blue vitriol) and pouring metal into molds and forming same into desired shapes and allowing metal to partially cool, and finally subjecting it to the action of sulphur until it is coated with sulphur oil and then allowing metal to harden.

PORTABLE FURNACE FOR MELTING STEEL OR OTHER METALS.—No. 792,619; L. Rousseau, Argenteuil, France.



In portable furnace for melting steel and other metals, combination with combustion chamber of juxtaposed circular chamber, conduits or flues connecting two chambers, supports fixed in second chamber, crucible resting on supports, conduit divided into two branches leading respectively under combustion chamber and into space around chamber, vertical rod crossing two branches, valve in each branch mounted upon vertical rod, two valves being located at right angles to each other, removable cover upon combustion chamber, tube projecting through cover and means for tilting furnace.

MACHINE FOR MAKING AND SHARPENING DRILLS.—No. 792,643; J. B. Word, Soulsbyville, Cal.



Machine of character described comprising base movable anvil on base provided with plurality of tools, means for operating any of tools, motor for shifting anvil, lever for starting and stopping motor, catch on base arranged to normally engage anvil and hold same in stationary position, and connections between lever and catch whereby when lever is moved to start motor catch will be disengaged from anvil, and when lever is moved to stop motor catch will be caused to again engage anvil and lock same in position.

The Commercial Development of Electro-Metallurgy.

Written for the MINING AND SCIENTIFIC PRESS by GEORGE E. WALSH.

The production of metallic carbides in the electric furnace has added greatly to the commercial development of a number of industries. Owing to the very high temperature required to fuse most of the carbides, the electric furnace is practically monopolizing the industry. A good many of the comparatively rare metals are now being utilized in different ways which make them of increasing importance, although before the electric furnace was developed it was impossible to produce such metals as tungsten, ferro-tungsten, molybdenum and vanadium at a cost that would make them commercially profitable. As alloys in manufacturing high-grade self-hardening and high-speed tool steel, tungsten, ferro-tungsten and molybdenum are important factors, and as they come out of the electric furnace in a compact fused mass, they are most advantageously used in the process of adding to the steel.

Calcium carbide can be produced at a temperature of 1500° C., and consequently it can be manufactured in the ordinary regenerative furnace, which produces a temperature ranging from 1500° to 1800° C. The oxy-hydrogen regenerating furnace yields another 200° C., and the possible range of temperature in this furnace is from 1700° to 2000° C. In the ordinary blast furnace, charged with coke and lime, with oxygen instead of air used, calcium carbide has also been produced.

But all the other carbides require the higher temperature of the electric furnace for their manufacture. With its additional temperature of some 1500° C., the electric furnace becomes a most important factor in fusing the carbides. The commercial development of carbides is thus due entirely to the practical adaptation of the electric furnace to industrial purposes. Most of the rare metals, and nearly all of the common ones, form carbides in the electric furnace when sufficient temperature is given.

The most important carbides formed of industrial metals are aluminum, tungsten, boron, molybdenum, silicon, thorium, uranium, calcium, strontium, sodium, barium and potassium. In nearly a dozen or two different industries these carbides have entered, and their employment is gradually revolutionizing manufacturing conditions to a remarkable degree. The carbide of silicon, which is now generally called carborundum, has completely changed our methods of grinding, scouring and polishing in many lines. The extreme hardness and abrasive qualities of this carbide makes its value world-wide, and its manufacture to-day is on such a large scale at Niagara that every industry can afford to use it. Even harder than carborundum is boron carbide, and if it were not for the fact that it costs more to manufacture it than carborundum it might in time displace the latter in many industries just as carborundum has displaced emery.

Calcium carbide, in its employment for the production of acetylene, is known the world over, but both barium and strontium would do equally well as the former for this work, but the more general occurrence of lime and its cheapness gives the calcium carbide the preference. Acetylene has extended its field rapidly, and to-day there are upward of 8000 acetylene installations of all capacities in active operation. More recently it has been utilized for power purposes, especially for driving gas engines. According to the tests made, 5.65 cubic feet of acetylene gas will develop one horse power, while 21.19 cubic feet of coal gas of ordinary quality are required for the same purpose. The small weight of calcium carbide makes it more useful in places where transportation is an item. In a good many mines a portable acetylene generator is used for lighting miners' lamps. Both for illumination and power purposes, the use of acetylene is thus extending, and the manufacture of calcium carbide is assuming proportions that make it of world-wide interest.

In the manufacture of carborundum on a large scale the use of ferro-silicon in the steel industry has been to a considerable extent displaced. Ferro-silicon has been an important factor in the steel trade as an alloy to prevent oxidation. In the casting of iron and steel ferro-silicon acts as a deoxidizer and thus relieves the process of the need of blowholes. Owing to the high heat of combustion, the metal is rendered more fluid for casting. The manufacture of ferro-silicon has extended a good deal in recent years, and several calcium carbide factories that did not prove profitable, owing to the competition, have turned to the production of ferro-silicon. The grade of metal thus produced varies greatly, all the way from 15% to 85%.

Copper silicon is also a good deoxidizer, and it has been used a good deal in copper and brass castings. It also increases the tensile strength of these metals. This is obtained from the electric furnace at a cost so low that it is likely to displace nearly all other alloys in the copper and brass casting factories.

In the manufacture of aluminum in the electric furnace a great impulse has been given to the electrical trade. The substitution of aluminum for copper conductors is one of the most important developments in modern long-distance transmission of electricity. Previous to 1898 aluminum was comparatively little known in the industrial world, but when it was manufactured in solid drawn conductors its use rapidly extended. There are three plants in this country producing aluminum, and six in Europe. The total water power employed for making the aluminum is nearly 40,000 H. P. As an electrical conductor aluminum is in some instances considered cheaper than copper, although not quite so efficient. The first use of aluminum conductors was for railway feeders, but its employment for telegraph and telephone lines is doubtful. For long-distance power transmission it is supplanting copper in many parts of the country. The long-distance lines of the Telluride Power Transmission Co. in Utah, Colorado and Montana use nearly 2000 miles of aluminum conductors, involving transmission distances of over 130 miles. Aluminum is not readily oxidizable, and for this reason its employment as conductors in mines and acid factories is considered important. While mineral acids affect copper conductors, they appear to have no chemical effect upon the aluminum conductors. In one particular there is an exception. Chlorine is detrimental to it, and where conductors are exposed to strong sea air or in the vicinity of chlorine works the disintegration of the metal is very marked.

The chief properties of the carbides which make them of particular industrial importance are their power to decompose water or to withstand oxidation. These properties are proving of great value in manufacturing as new methods are discovered for utilizing them. There are five of the carbides produced by the electrical furnace which are nearly inert or normal so far as the oxidizing action of water or atmosphere on them is concerned. These are boron, silicon, titanium and zirconium. On the other hand, barium, thorium, calcium, lanthanum, uranium and cæsium are strongly acted upon by water. Between these two extremes all the other carbides experimented with lie. In the decomposition of water similar differences are noticed. In the reactions, carbides of calcium, barium and strontium produce acetylene, manganese carbides evolve a mixture of methane and hydrogen; the cerium group produces methane and acetylene, and thorium and uranium yield in addition to the latter a certain amount of hydrogen.

A few of the rarer metals have only very recently been tested in the electric furnace, but their application to a number of industries is indicated. Quite recently ferro-titanium and ferro-vanadium have been manufactured in the electric furnace, and they proved of considerable value in the steel industry. The demand for higher grade steel is one of the phases of manufacture that is stimulating chemists to greater effort in the industrial application of their art. With the employment of electricity for driving steel tools the need for harder and more resisting steel is apparent, while the manufacture of armor plate to resist modern projectiles requires chemical composition of steels that will make it better than heretofore. Nearly every metal known to the world is being experimented with in the modern laboratory to evolve some harder variety of steel.

According to some of these modern tests, it has been found that the addition of titanium to pig iron greatly increases its tensile and transverse strength, while a similar but less marked effect is obtained with steel. Other of the rarer metals have been used in a similar way with varying success. In dealing with all of these metals the electric furnace is essential, for the high temperatures needed cannot be obtained in any other way, and the blast or regenerative furnace cannot be kept under such perfect control as the electric furnace. Owing to the development of the electric furnace, the waste of material is greatly minimized in these experiments. At Essen, Germany, where some of the most successful tests with rare metals have been made, the metallic oxides are reduced by finely divided aluminum

In this connection a word regarding the smelting of ores by the electric furnace should be added. Recent improvements have indicated some great developments in this direction. While the electric smelting of iron ores and the manufacture of steel by the electric process have limitations, especially in the relative cost of the operations, it is quite evident that there is a field for successful work in smelting certain titaniferous ores which are frequently very low in phosphorus, sulphur and silica, but high in titanic acid. Such ores cannot be treated in the ordinary blast furnace process, and heretofore they have been rejected. In the electric process such ores can be treated successfully, and considerable advance has been made in the manufacture of steel in Newfoundland by using this method. Large deposits of titaniferous ores are found on the island of Newfoundland, and they have not heretofore proved profitable to treat. There is also an abundance of available water power near the mines, while coal is scarce. By utilizing the electric current generated by water power, it is indicated that these huge deposits of titaniferous ores can be made of great commercial value.

In the treatment of copper-nickel matte obtained from the Canadian ores, the electrolytic refining plant at Sault Ste. Marie has been very successful. Nickel-steel is becoming more useful in a variety of ways every year. The railways have taken it up for a number of purposes, and the increased consumption thereby demands a larger adoption of electrolytic processes for refining the crude nickel. By the ordinary metallurgical processes raw nickel has been refined to test 99.2, and as a result of this improvement it is not likely that the electrolytic process will be adopted to remove the last traces of impurity except for special purposes. Where pure nickel is required the cost must be of secondary consideration, and in this connection the electrolytic process is the only one that can produce the desired results. If the impurities left in the nickel were silver and gold, it might pay for the extra expense of the electrolytic process simply to recover these metals. But the impurities are not of this character

The development of water power for electro-chemical and electro-metallurgical purposes has increased in the past few years remarkably, both in this country and Europe Heretofore the water power developed has had little reference to the location of the metal mines. Niagara and Messina have attracted the attention of the engineers and the great plants established there are in many cases far removed from the mines from which the different ores are extracted.

A change in this policy is now apparent. A better study of the available water power among the mountains has shown that it is possible to secure large electric current close to the mines, and with the two brought close together in one plant the process of refining the metals is greatly cheapened. In the mining regions of Montana, California, Colorado and Utah large electrical currents have been developed by private companies for operating mine hoists, pumps and general machinery, and it is now only one step farther to use the same current for electrolytic refining plants. Electro-metallurgy will thus take another step in advance and become of more practical value to the mine owner and operator than ever before.

THE PROSPECTOR.

The rock samples from Mercur, Utah, are as follows: No. 1, a much decomposed quartz porphyry, in which the quartz grains are almost microscopic. No. 2 is undoubtedly a portion of the same rock mass as No. 1, but is impregnated with carbonaceous matter, which on ignition turns white, like the original porphyry. No. 3 is the same, but has been rendered shaly by pressure. It also is heavily impregnated with carbon. This black material in appearance resembles pyrolusite, but no reaction for manganese was obtained. No. 4 is a decomposed porphyry, apparently somewhat different from No. 1. Its finer grain may be due to its occurring in thinner sheets. No. 5 is a fossiliferous clay rock, and No. 6 the same, but stained with iron oxide. It also is fossiliferous. No. 7 is a coarse-grained hornblende granite, in which occurs molybdenite and a little chalcopyrite.

The samples from Caribou Crossing, Y. T., are as follows: No. 1, diorite-aphanite. No. 2, quartz, with what is probably a decomposing gray copper, probably rich in silver. No. 3, quartz, with decomposing arsenical sulphide. No. 4, quartz, containing a decomposing iron-copper ore, stains of green copper carbonate—malachite. No. 5, jasper, carrying a little pyrite. No. 6, an altered intrusive rock, probaby diorite. The hornblende has been entirely removed, leaving only spots of iron oxide. No. 7, felsite. No. 8, crystallized vein quartz, in which are seen galena, zincblende, bornite (copper sulphide) and pyrite. The silver-bearing metals in this ore which can be identified are pyrargyrite (antimonial ruby silver) and argentite (black silver sulphide). There are probably other silver minerals present, but in too small quantities to be identified. No. 9, quartz, containing copper sulphide, altering to azurite. No. 10, quartz, with ruby silver and argentite. There is also, probably, some silver chloride present on one side of the specimen, but it is too small to be detected.

The rock samples from Sweetwater, Shasta county, Cal., are: 1. Limestone. 2. Chlorite schist, altered from a massive greenstone, probably diorite. No. 3 is also chlorite schist and contains iron sulphide and some chalcopyrite (copper-iron sulphide). No. 4 is novaculite; probably a silicified limestone. No. 5 is garnet. 6. Amphibole (hornblende). 7. Silicified dike rock containing cuprite (red oxide of copper). 8. Bornite. 9. Magnetite. 10. Pyrrhotite, a magnetic mono-sulphide of iron; the latter is too low in sulphur to make acid making profitable in this country, although it is used to some extent for that purpose in Europe. 11. Zincblende; it probably contains considerable iron.

The rock from Franklin Camp, B. C., is diabase. It contains finely disseminated chalcopyrite and bornite—sulphides of copper.

The rocks from Calico, Cal., are: 1. Hornblende andesite. 2. Liparite, a variety of rhyolite. 3. Sandstone, the material being from the disintegration of volcanic rocks, probably rhyolite. 4. Shale. 5. Jasper. 6. Rhyolite; the dark specks are silver chloride.

Tonopah, Nevada, and Its Development.*

There are few instances in the brief history of Nevada, which teems with the story of discovery, development and herculean achievement, more interesting than that of Tonopah. Prior to the discovery by Jas. L. Butler of the rather unpromising ore on the mountain side at the foot of the hill now known as Mount Oddie, Nevada's mining industry had declined almost to the point of stagnation. Outside of the operations on the Comstock, at De Lamar, and in the southeastern end of the State about Searchlight, desultory operations only were being carried on, in a listless sort of way, at the numerous camps throughout the State. The famous old camps of Pioche, Eureka, Austin, and some others were doing little or nothing, while the great desert stretching across the southern end of the State offered little of immediate promise. It was known that mineral existed in some of these southern hills and mountains, for in former years energetic men had explored and developed more or less extensively the districts of Reveille, Logan, Hiko, Good Springs, and some other camps, but these mines had either ceased to pay, or did not possess the elements of success, and were therefore unattractive to the average fortune hunter. Still through this period of depression there were venturesome prospectors who annually made pilgrimages into this southern desert, lured by the possibilities of the discovery of a "Gunsight," a "Breyfogle," or some other mythical bonanza.

James L. Butler was one of these. He made his headquarters temporarily at Belmont, the most southerly of the several outfitting points for the desert to the southward. He was going to the region south of the present town of Tonopah, where some discoveries had been made in a camp called Southern Klondike. He arrived late one afternoon at the foot of Mount Oddie, where he made a dry camp. From force of habit he looked about the vicinity, and noticing some quartz croppings, like an experienced prospector took several pieces of the

Croppings on the Desert King, Twenty Feet Wide, in Alaskite District, Eight Miles Southeast of Goldfield, on the Road to Bullfrog, Nevada.

rock with him for test. He carried them southward with him and handed them to an assayer at one of the southern mines, who did not consider them promising enough in appearance to assay them. Butler himself did not feel particularly elated over the find. After a time he returned northward toward Belmont. It is the habit of desert travelers when on these trips to camp in the same places if the previous visits had shown the place to be satisfactory, therefore it was not strange that he found himself under the shadows of Mount Oddie once more as evening came on at the end of a cheerless day on the desert. Once again following his natural impulse to pick up anything that looked like ore, he gathered a quantity of samples, took them with him to Belmont, showed them to T. L. Oddie of that town, who agreed to have them assayed for an interest in the claims. The samples were sent to an assayer by Mr. Oddie, who promised one-half of his interest in the claims if he made the assays. The rock, unpromising as it appeared, proved to be astonishingly rich.

This all occurred in 1900. Mr. Butler, immediately upon receipt of the assays, went to Mount Oddie and located several claims. In doing the assessment work two tons of sorted ore were sacked and shipped to Selby's. This shipment netted $600, and from that time on the development of the new camp was rapid. A number of leases were given miners on the Mizpah and Valley View claims, and the desert slope quickly became dotted with the tents of miners, prospectors, merchants and adventurers of every description. The accompanying engravings, for which we are indebted to John D. Hoff of San Francisco, Cal., show clearly the results of the tremendous activity which has been the most marked feature of the development of Tonopah, the superfluous energy extending its influence out over the surrounding desert regions in all directions and resulting directly in the discovery of the several camps of the Goldfield district, Bullfrog, Lone Mountain, Gold Mountain, Kawich, as well as a revival of mining in the old camps of Lida, Reveille and half a dozen other localities where for many years it has been known that mineral existed, but which, owing to their isolation, could not be profitably worked. Tonopah has changed all this.

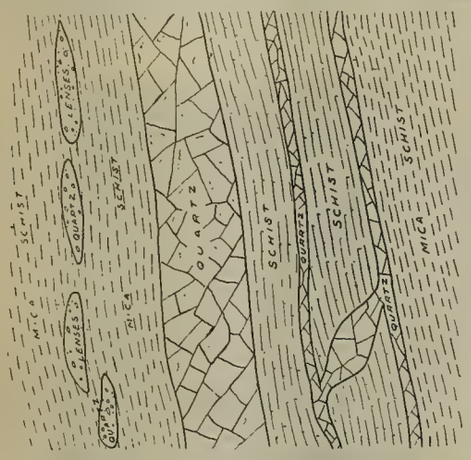
Gold Mines in Schistose Rocks.

While many gold mines in schistose rocks are of a somewhat erratic character — lenses of quartz without continuity — but succeeding each other along a general course, nearly coincident with the schistosity of the rocks, there are other types of veins approaching fissures in their structure in schistose rocks. When the vein cuts across either strike or dip, or both of the country rock, there can be no doubt of its character, but sometimes the stress which has produced the vein has been such that the rocks are crushed, flexed and even faulted to a greater or less

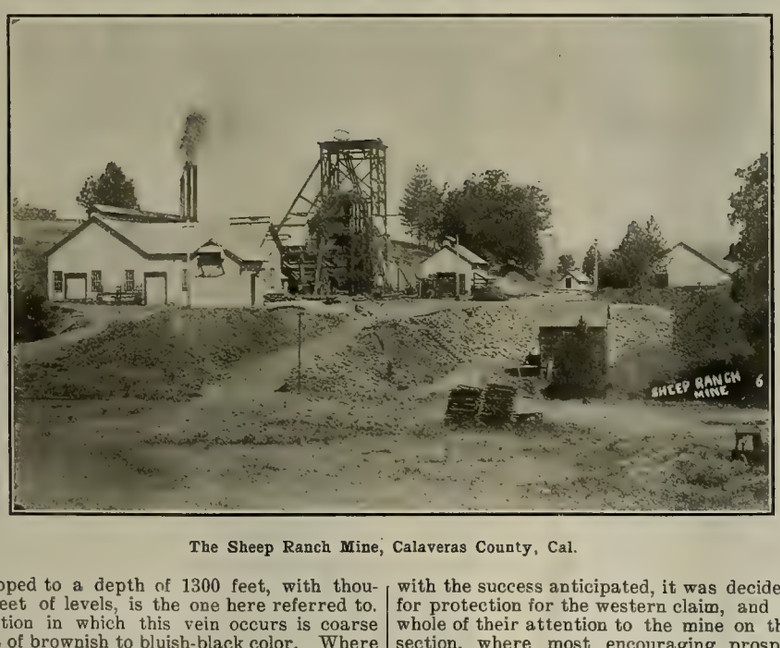


Cross Section Vein 1200 Level Sheep Ranch Mine, Calaveras County, Cal.

extent, thus forming a series of lenses of fracture, with occasional actual displacement of the rock masses adjacent to the line of disturbance and on either side of it. When these movements take place there are certain blocks which suffer displacement, and other blocks which are only subjected to stress, as indicated by the crumpling of the rocks. This results in one portion of the vein having the appearance of a fissure with walls, while in another portion the ore is "frozen" to the walls, or there is only a crumpling and crushing of the fragments of schist with little or no deposition of quartz. In some instances the latter are undoubtedly the result of movement which has taken place after the deposition of quartz in the vein had ceased.

The Sheep Ranch mine in Calaveras county, Cal., is of this type. There are five or more veins in the property, but the main Sheep Ranch vein, which has been developed to a depth of 1300 feet, with thousands of feet of levels, is the one here referred to. The formation in which this vein occurs is coarse mica schist of brownish to bluish-black color. Where this rock has been subjected to pressure and sheaving near the vein the schist has the appearance of foliated black slate, which has led some who have previously described it into the error of stating that the walls were slate. The schist is cut by dikes of diorite and pegmatite granite. This vein is, so far as known, the hanging wall vein of the series. It is from an inch or two to 3 feet in width, having an average of 18 inches. Much of the quartz from this vein was high grade, and gold could readily be seen in much of it, particularly in a dark-bluish, almost black, vitreous quartz, occurring in rolls and lenses where the formation was much crumpled. Ordinarily the vein quartz occurs as a continuous waving vein, or, as previously mentioned, as a succession of disconnected lenses. The accompanying sketch shows a characteristic cross-section of the Sheep Ranch vein and was sketched on the 1200 level. At times the several stringers and independent accompanying lenses disappear, there being but one vein, and again only the lenses, or a series of stringers can be observed. The mine paid from its earliest history and is credited with having produced over $3,000,000 in gold.

The accompanying engraving shows the hoist and mill built a few years ago. The mine is equipped with both steam and electricity.



The Sheep Ranch Mine, Calaveras County, Cal.

Mining in Waihi District, New Zealand.*

One of the most important gold mining districts of New Zealand is that of Waihi. In this district the property of the Waihi Gold Mining Co. is extensively equipped and developed. Concerning it the report of the Minister of Mines has the following:

This company's works are increasing to considerable dimensions, and up-to-date machinery is being obtained to replace that which formerly was sufficient for the requirements. A large winding plant is in the course of erection at No. 1 shaft, which will be capable of hauling up two trucks at a time instead of one, thus enabling the company to increase the output from the mine should it be required, or in the event of any stoppage in the other winding shafts through accidents or otherwise, a sufficient supply of quartz could be hauled up this shaft to keep the batteries running. A powerful pumping plant is in the course of erection at No. 5 shaft. This, together with the present engine now doing most of the pumping on the same shaft, will, it is supposed, be capable of unwatering the mine to a depth of 3000 feet.

The work of development in the mine is being vigorously proceeded with, and, as the lode system is opened up from day to day, new discoveries are being made and the value of the mine becomes more apparent, proof of which is shown by the handsome returns obtained from the ore as it is broken out.

At Waikino mill, (see illustration front page), great improvements and additions are being made. The most important in hand is the erection of a plant to treat the concentrates, which have for some time past been transmitted to New South Wales for treatment. From tests already made, this new plant will put through a large tonnage, and the extraction will be as good as that at the works in New South Wales.

WAIHI-GRAND JUNCTION GOLD MINING CO., LTD.—This company has two claims. One is situated on the western side of the Waihi Company's mine and the other on the eastern side, and they comprise 90 and 190 acres, respectively. As the claims do not adjoin each other, they have to be worked as two separate mines. At the beginning of the year the company was carrying on prospecting work in both mines, but after a few months' work, not meeting with the success anticipated, it was decided to apply for protection for the western claim, and direct the whole of their attention to the mine on the eastern section, where most encouraging prospects were being obtained. While working on the western mine a large amount of sinking, driving and raising was done to effect communication between B and C shafts for ventilation, and when this was accomplished, a crosscut drive was put in a distance of 56 feet, where the reef was intersected, and driven through and found to be 14 feet wide. The quartz consisted chiefly of large blocks of oxidized ore and, on tests being made, it was found to be very low grade. In the eastern section communication had been made between Nos. 1 and 2 shafts, which has given excellent ventilation to this portion of the mine, but to complete this work, 243 feet of raising and driving had to be done at a considerable cost. At No. 2 level the drive on the lode was extended for a distance of 26 feet, for the purpose of reaching the Waihi Company's boundary. In the northeastern drive on the lode at the same level, the drive has been extended a distance of 304 feet and four winzes opened out and sunk for a short distance below the level. The lode here, I am informed, at each place gave satisfactory results, and the company has every confidence that this portion of their mine will prove to be highly payable at greater depth. At the bottom of No. 1 shaft the No. 3 level crosscut has been driven a distance of 167 feet. In the month of May the directors decided to test the lode at a depth of 1000 feet by means of boring, and let a contract to the Goldfields Diamond Drilling Co., Ltd., to put down a bore from the 500-foot level at an angle of 68½°. At a depth of 458 feet the first quartz was met with, and the bore was to all appearance in lode formation, until the supposed foot wall of the lode was reached at a depth of 784 feet. The company intends shortly to commence sinking the No. 1 (main) shaft to a distance of 750 feet, where a crosscut drive will be put in to intersect the lode. An average of twenty-nine men have been employed.

WAIHI EXTENDED MINE.—This company's operations have been directed to crosscutting north, south and westward at the 500-foot level, with the object of discovering the Waihi Company's lodes. In several places quartz and silica veins running through the country were met with, and what appeared to be the hanging wall of a lode was followed for some distance, but as the Grand Junction or Waihi Company's lodes have not been met with (although striking direct into this company's ground) the manager is of opinion that the lode will not be found until a greater depth is reached, on account of the broken nature of the country. A total of 830 feet of driving has been done during the year. An average of ten men have been employed.

WAIHI GLADSTONE.—Operations in this mine (which is worked by a syndicate) have not turned out as successfully as was anticipated. The small 5-stamp battery which the owners erected on the property was completed about the middle of the year, when crushing operations commenced for the purpose of testing in bulk the value of the ore won from the different prospecting and development workings of the mine. The reefs vary from 1 foot to 6 feet in width at different points of the property. The method of treatment adopted was wet crushing and plate amalgamation. Up to the present, however, the results obtained have not proved of a payable nature. The total quantity put through the mill was 400 tons of quartz, from which 47 ounces 10 pennyweights of gold was obtained; value, £115 3s. 9d. An average of six men were employed.

WAIHI SOUTH.—All work in this mine is stopped for the present, pending negotiations with the Goldfields Diamond Drilling Co., Ltd., for a series of bore holes to be put down on the property to locate any ore body that may be traversing the ground at a depth, previous to incurring a large expenditure in machinery, etc., to enable deep sinking to be undertaken. In the early part of the year work was carried on in the Waihi-Grand Junction West mine by this company, but when the aforesaid company stopped operations here, the Waihi South Company could not carry on the work they had on hand at the time on account of the large amount of water to contend with.

WAIHI CONSOLS.—This company is directing attention to boring, with the object of discovering any lodes that may run through their property at a depth, and a contract was let in October last to the Goldfields Diamond Drilling Co., Ltd., to put a hole down 1200 feet. At the end of the year the hole had reached a depth of 262 feet.

WAIHI CONSOLIDATED.—There has been very little work done on this ground during the year. A contract was let for boring, and a start was made with the old machine that was on the ground, but this not being good enough for the work, operations were temporarily suspended until one of the Goldfields Diamond Drilling Company's machines arrived.

OHINEMURI RIVER SYNDICATE CLAIM.—The syndicate has gone to considerable expense in the erection of houses and machinery, and although temporary trials of the machinery have been made, and also experiments to find out the best mode of treating the tailings, the work is practically at a standstill until a grinding machine is installed. It is confidently assumed that the sands will then be treated efficiently and economically, and thereby a payable concern made of the venture. An average of ten men have been employed.

* See illustration front page.

PROBABLY the best and simplest test of the road making value of an oil is to evaporate a weighed sample in an open metal dish, down to the hardness of commercial 'D' asphalt, and weigh the residue. We thus get at once both the original asphalt and that formed during evaporation, and while it is not likely that the percentage of asphalt thus obtained is the same as would be gotten by allowing the oil to dry in the sun, yet it is highly probable that the comparison between different oils thus made is accurate. This test requires no apparatus except an iron or copper pan, a scale, and a plumber's fire pot, though it must be admitted that the even grading of the asphalt requires care and a little skill.

CALIFORNIA STATE LIBRARY.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

During 1904 the production of mica in the United States was confined to the following States, given in the order of the importance of production: North Carolina, New Hampshire, Colorado, New Mexico, California, Georgia, South Dakota, Connecticut and Idaho. The total quantity of sheet or plate mica produced in the United States during 1904 as reported to the United States Geological Survey was 668,358 pounds, valued at $109,462, an increase of 48,758 pounds in quantity, but a decrease of $8626 in value, as compared with a production of 619,600 pounds, valued at $118,088, in 1903. The reports of sheet or plate mica for 1900, 1901 and 1902 were 456,283, 360,060 and 373,266 pounds, respectively. It appears that in 1903 and 1904 the production was nearly 300,000 pounds greater than in 1901 and 1902. This large increase in the production of sheet mica during the last two years is due to the very large quantity of the small sized disks and rectan ular sheets of mica that have been prepared for electrical purposes. The production of scrap mica during 1904 amounted to 1096 short tons, valued at $10,854, as against 695 short tons, valued at $6460, in 1903. During 1903, however, there were also reported 964 short tons, valued at $18,580, which were sold in the rough blocks as produced. This probably made at least 800 tons of scrap mica, so that the actual production of scrap mica in 1903 was greater than that in 1904. Of the 1904 production 610,121 pounds of sheet mica, valued at $100,724, and 200 short tons of scrap mica, valued at $2000, were produced in North Carolina. This was over nine-tenths of the total production of the United States in 1904.

ALASKA.

Gravel washing has been commenced at the Jualpa mine, near Juneau, under the direction of W. H. Hile. ——Superintendent G. Otterson, of the Mansfield Co., has leased the Nowell placers in Silver Bow basin, near Juneau, and will open the camp on July 1.

ARIZONA.

Cochise County.

The Cochise Con. M. Co. is contemplating putting in a 50-ton reduction plant at the Davis group, 5 miles northeast of Paradise. The ore occurs in limestone and carries values in lead, copper, zinc, gold and silver. H. Alexander is manager. ——The Manhattan Development Co., working near Paradise, is considering putting in machinery for development. F. W. Hoar of Paradise is superintendent.——J. A. Lewandowski of Douglas, president of the Savage Con. G. & C. Co., is building a small matting furnace at the company's mines, near Paradise.——The Planet shaft of the Chiricahua Development Co., near Paradise, is down 450 feet and is to be continued to the 1000-foot level. F. W. Hoar is superintendent.——The main two-compartment shaft of the Shattuck Arizona C. Co., near Bisbee, is down 675 feet. A station is to be cut and drifting started, as a 15-foot lens of ore was cut at 525 feet. B. M. Pattison is superintendent.

Gila County.

(Special Correspondence).—The Arizona Commercial Copper Co., W. S. Sultan, superintendent, have put in a new hoist and other machinery in the mine, near Globe, and are developing the mine.——The Black Hawk shaft is down 115 feet. The crosscut at the 100-foot has opened an ore body which assays high in copper and silver.——At the Old Dominion plant the automatic conveyors and crushers have been tested and found to work satisfactorily and all the ore from the mine is hoisted through the new shaft and handled by the conveyor system. Rapid progress is being made in sinking the shaft below the twelfth level, having reached a depth of 80 feet below that station. The smelter is maintaining its average output of 100,000 pounds daily.

Globe, June 26.

The Inspiration M. Co., 10 miles west of Globe, J. D. Coplen manager, has run three crosscut tunnels, the Clipper, the Woodson, the Mercer, and the Martin. A small concentrating plant is to be built.

Mohave County.

The German-American 10-stamp mill and cyanide plant, near Acme, has been started. The mill has 950-pound stamps, 7-inch drop, 100 per minute, and is run by a gasoline engine. O. F. Kuencer is superintendent. ——The Fay shaft, south of Kingman, is being sunk deeper and it is reported that machinery for deep sinking is to be placed on the property.

Pima County.

It is reported that the Arizona mines, south of Tucson, are being worked by the Mineral Hill Con. M. Co., who will build reduction works this fall.

The double-compartment shaft of the Weeden mine at Pittsburg will be sunk 600 feet. The smelter is turning out ten tons of copper matte daily. D. Dryer is superintendent.

Pinal County.

The Saddle Mountain M. Co. has 100 men employed on the San Carlos strip erecting a 180-ton smelter and in the development of their copper property. Supplies for this property are now being unloaded at Winkleman and are freighted from that point to the mines, at Dudleyville, a distance of 14 miles.

Work is to be resumed on the Aboriginal mines, at Cochrane station, on the P. & E. Railroad, 10 miles from Kelvin. The property is owned by J. S. Cochrane of Cochrane, A. L. Jones of Phœnix and F. Harvey of Kelvin.

Santa Cruz County.

(Special Correspondence).—The Mowry mines at Patagonia, operated by the Mowry M. Co., have been developed to a depth of 600 feet. The several shafts have been unwatered and development is again under way. Larger hoisting and pumping plants are being put in and better reduction works have been ordered. The ores, which are sulphides of lead and copper associated with gold and silver values, occur in lime gangue inclosed in granite walls.

Patogania, June 25.

Yavapai County.

The working shaft of the Swiss Girl mine of the Baumann Copper Co., at Dewey, is down nearly 200 feet.—— H. Bowdre of Turkey creek reports that new camps are starting up in Pine Flat, Crook canyon and in the Palace station neighborhood. M. Ryan of the Wisconsin-Arizona Co. is working on the company's properties.

The United Verde Copper Co. at Jerome is regrading the old 300 roast grade and placing trolley wires thereon, preparatory to again using it.——At the Black Hills Co.'s property, south of Jerome, two shifts are at work unwatering the mine.

L. C. Haynes of New York City has bonded the Harryhousen claims near Jerome. He has started drilling in the Verde Chief. D. L. Bartholdi is superintendent.

CALIFORNIA.

Calaveras County.

E. C. Wood, consulting engineer for the Essex Consolidated Mines Co. of Angels Camp, says that the property has been opened up by three long tunnels and one shaft 660 feet deep. A 40-stamp mill on the property has been in continuous operation since April.

El Dorado County.

The Good Luck M. Co. has been formed to work the Good Luck mine, near D amond Springs.

Fresno County.

A big flow of oil has been struck in the Coalinga district by the California Monarch Oil Co. After a great waste of the petroleum the flow was placed under control, and it is now rising through a 6-inch pipe at the rate of 3000 barrels daily. —— H. J. Greva of Coalinga has made a location on the headwaters of the San Benito, near Hollister, for a water right to take water into the Coalinga oil district by means of a tunnel through the mountains.

Kern County.

The experimental deep well of the Santa Fe in the Kern River oil fields is down more than 2000 feet and the drill has penetrated a stratum of light oil of 30° gravity. This is the most important discovery in the Kern fields since the first find of oil, as the oil is so much lighter than that now being pumped. The shallower wells now being developed give a much heavier oil, and during the last few years the output has been gradually decreasing. The work of deepening the old wells will be begun at once.——The Standard Borax Co. of Bakersfield is working near the boundary line between Kern and Ventura counties. J. Werrington and J. A. Flood are interested. J. B. Berges has charge of the work.

Mono County.

R. Mitchell of Bridgeport, superintendent of the Dunderberg M. Co., has bought one-half of the Castle Grande mine, owned by J. C. Douglas and Osborne, for $2500.

Nevada County.

Gold discoveries are reported at Deadman's Flat, west of Grass Valley.

Placer County.

It is reported that H. Bernard has bonded the Evening Star mine, on Rock creek, to O'Neal & Scribner of Oakland, who will put in new machinery.——The Dunlap property, below Auburn, has been bonded by M. Repose.

San Bernardino County.

(Special Correspondence).—Beck & Body are developing the Sunrise group, 8 miles from Sandy, Lincoln county, Nev. A winze is being sunk in high-grade ore, with values in gold, silver and lead. C. H. Beck has charge.

Sandy, Nev., June 28.

Santa Barbara County.

The New Pennsylvania Oil Co. has reached the oil sand in its first well in the Santa Maria field at a depth of 1350 feet. Santa Maria wells have struck oil at a depth of over 2000 feet. The well is 3 miles from Orcutt, and one of the branch pipe lines of the Standard Oil Co. will be extended to it.

Shasta County.

The Dobrowsky mine, near Shasta, is being worked by W. H. Nofsinger and W. H. Johnson who have a lease in which H. O. Cummins, manager of the Middle Creek G. M. Co., has become interested. They have 21 men employed grading the site for the new mill. The new steam hoist has been started. Crude oil is used for fuel.

Sierra County.

O. Owens and E. Jones report the Columbia tunnel near American hill, near Downieville, is in nearly 1700 feet, and after being run 100 feet farther an upraise will be made to strike the channel. J. M. Harper is manager.——J. Hayes and F. Somerville of Sierra City, who, together with L. D. Flint and R. Parker, own the King Quartz mine near Sierra City, intend building a 20-stamp mill on their property.

Siskiyou County.

The management of the Headwaters group of mines at Humbug, 18 miles from Montague, intend pumping out and will run a tunnel into the mountain for drainage, tapping the ledge 150 feet below present workings. G. W. Cooper of Yreka has signed a contract for the construction of a $3000 mill building at the Headwaters mine, which does not include the machinery for same. The present stamp mill and machinery will be used, with additions, including a cyanide plant.——F. W. Mahler of Cherry Creek has sold his Drummer Boy quartz ledges to E. W. Emmons of New York City.——McFerrin, Zimmer & Dingman of Fort Wayne, Ind., have leased the Freshour property, on Klamath river, in Virginia Bar district, and are sinking a shaft to bedrock, with the intention of running four drifts from the shaft to find the pay channel. A. Thrash of Humbug is superintendent.

John M. Tetherow, superintendent of the Highland mine, near Etna, states he will put in a new mill at once.

Yuba County.

The Peerless Gold & Silver M. Co. has been formed by J. Byrne and J. Peardon, Sr., of Smartsville and R. P. McKay, C. Metteer and M. L. McKay of Marysville to purchase and develop the Peerless gold and silver claim, west of Smartsville.

COLORADO.

Boulder County.

The first cyanide mill to prove a success in Boulder county has been opened up in Magnolia, 10 miles from Boulder. It is owned and operated by F. Leonard of Magnolia and is treating ore from the Cash mine. Straight cyanide and an oxidizing roast are the principal factors of his method. He is still somewhat uncertain about the cost of treatment, but estimates that it will not exceed $2.50 per ton, at the highest.

Clear Creek County.

The Independent M. Co. is working the East Griffith, near Georgetown, with J. Larsen of Idaho Springs as resident superintendent.

Work has been resumed on the St. Paul & Colorado M. Co.'s claims on Lincoln mountain, near Georgetown, with W. M. Lewis as manager. It is stated that a power plant will be built at which time power drills will be used in driving the bore.

A test in the cyanide section of the Ward mill, near Idaho Springs, on 104 tons of raw iron and lead concentrates containing gold and silver values of $16.80 per ton, after nine days of leaching, during which the cyanide consumption was 2.4 pounds per ton, showed an extraction of 74.3% of the contents. The tailings, which have been running to waste into Chicago creek, are being placed in the cyanide tanks for treatment. The tailings carry values of from 96 cents to $1.82 per ton, and commercial tests have shown that nearly a complete saving can be made at a cost not exceeding 38 cents per ton. ——S. Anderson of Idaho Springs and W. Lamb are sinking the main shaft on the Griffith vein, near Georgetown, owned by Maxwell & Hood.

At the Hazelton-Santiago mines at Argentine and Brown mountain the proposed mill and tramway are to be constructed, says W. Rogers, the president and general manager. He plans to build a tramway 8000 feet in length to connect the Santiago with Baltimore tunnel, on the Hazelton group, near Silver Plume, and the Colorado & Southern Railway, for convenience and economy in conveying ore to the mill which is to be erected there. Stamps, jigs and concentrating tables, supplemented by cyaniding, will be employed.

Chaffee County.

The Black Hawk mine at St. Elmo, in the Chalk Creek district, expects to put in an electric separator to concentrate the zinc ores. The mill is to be put up at the foot of Baalbec gulch, 2300 feet from the mine. An aerial tramway, with a capacity of 100 tons a day, will be built from the mill to the mine. The Black Hawk has been operated for several years by the Mary H. M. Co., of which T. B. Crawford is president.

Custer County.

M. Moore and Abbott have charge of work on the California claim, on Game ridge, near Silver Cliff. They intend to put in a hoist. Moore has also been cleaning out the India tunnel for the owners.——Work has been started on the Bridgeman's Hope claims in Junkins park.——It is reported that C. Haskell, manager of the Hector mine, near Silver Cliff, is making arrangements for working the mine and for putting in a cyanide mill.

Gilpin County.

The following is the new schedule of smelting rates for the Clear Creek valley mines, adopted by the smelter trust, which went into effect on June 20, the prices governing the settlement of all ores purchased by the Chamberlain-Dillingham Ore Co., at Black Hawk: $19 per ounce for gold when the ore contains $\frac{5}{10}$ to 2 ounces, $19.50 per ounce when over 2 ounces, 95% of the value of silver, when 2 ounces or over. On copper, $1.25 per unit, up to 5%; $1.50 per unit up to 10%, and $1.75 per unit over 10%.

ORES CARRYING OVER 65% SILICA.

Gross value and under—	Treatment.
$14	$ 4 00
Gross value—	
$14 to $20	5 00
$20 to $25	5 50
$25 to $30	6 00
$30 to $35	6 50
$35 to $40	7 00
$40 to $45	7 50
$45 to $50	8 00
$50 to $75	9 00
$75 to $100	10 00
$100 and over gross value	11 00

ORES CARRYING LESS THAN 65% SILICA.

Gross value and under—	Treatment.
$20	$ 5 00
Gross value—	
$20 to $25	5 50
$25 to $30	6 00
$30 to $35	6 50
$35 to $40	7 00
$40 to $45	7 50
$45 to $50	8 00
$50 and over gross value	9 00

TAILINGS AND CONCENTRATES

Minimum price, $6 per ton; excess of silica over 10% deducted from $6.

	Treatment.
$35 per ton and under	$ 3 50
$35 to $80 inclusive	4 00
$80 and over	4 50

To these different prices should be added the freight and sampling charges.

G. C. Easton of Denver has started work on the Lakeside tunnel, near Apex.

Mollow & Co. of Russell Gulch, operating the Gem mine on Bellevue mountain, are preparing to put in a hoisting plant.——Sinking operations have been finished at the Chicago-Carr mine on Bobtail hill, near Central City, this lift making the shaft a total depth of 600 feet. Manager B. Meyers says that as soon as the drifts are in a safe distance from the shaft sinking operations will

again be resumed with the intention of going down another lift of 80 feet.——The Castleton mine, at the head of Virginia canyon, and operating under the management of W. Kirk, is shipping daily to the concentrating mills at Idaho Springs.

Owing to a strike at the stamp mills on North Clear creek at Black Hawk, the owners have adopted an eight-hour day. At the Bobtail an eight-hour day has been adopted at $2.50, where it was $3 for twelve hours, and will be worked with special shifts, a temporary agreement to that effect having been made. The Buell mill is working on the eight-hour scale awaiting advices of the manager in Denver, and at the concentrator it is believed that an eight-hour agreement will be reached. The Gilpin, Polar Star and Randolph mills did not start work to-day.

Gunnison County.

At Camp Sherrod the Sunlight G. M. Co., working the Bacon tunnel, has found good ore after running 200 feet.——The N. B. C. Co. has let a contract for 500 feet of tunnel into Brittle Silver mountain, near Gunnison. ——The Glen Park Placer M. Co., operating on the north side of Cross mountain, 8 miles west of Tin Cup, is preparing to resume work on its gravel beds. The Glen Park people have constructed 900 feet of flumes and have two dams and a reservoir. S. G. Bradford of Denver is superintendent.——The West Gold Hill M. & M. Co., operating in Tin Cup district, has contracted for an aerial tramway of one span, 2250 feet long, without a tower, to convey ore from the mine to the company's mill. A special 1½-inch cable is being made that will put the entire line on the gravity system. It will carry ten tons an hour.——Geo. Williams, manager of the Congress G. M. & M. Co., operating at White Pine, reports that the tunnel has been driven 150 feet and that an electric light and cyanide plant has been ordered.

G. Kellogg, operating the Chloride, at Pitkin, will unwater the lower levels of the mine in July and resume work at that point.

The A. R. C. M. & M. Co. at Sherrod, L. J. Ross president, has decided to drive a crosscut tunnel 350 feet deep, which will cut the main vein at depth of 267 feet.

The Raymond ore bodies at Pitkin have been gone over by experts, reserves of ore measured, ores tested in carload lots, and the management has decided to build a 30-stamp mill at once. K. Neitzel, late superintendent of the Portland mill at Colorado City, will have charge of the erection and afterwards of the mill. The ground is being surveyed and plans drawn. The Raymond tunnel has four veins to draw from, outside of the Raymond proper, which has not yet been cut. The tunnel to this point will be started soon.——The Leona claims, west of Bowerman, at the head of Grant gulch, is owned by the Bessemer M. Co., composed of Pueblo parties, with A. H. Baxter in charge of the work. A shaft has been sunk 72 feet.——The drainage tunnel being run by I. L. Johnson into Gold hill from Middle Willow creek, near Pitkin, is in 200 feet. A pipe line has been laid from the compressor, 3000 feet distant, and air drills are being used. The tunnel is to be driven under the Gold Cup workings at a depth of 400 feet by following the dip of the vein.

Ten feet of high-grade zinc ore is said to be showing in the Napoleon and Edna Draine properties on Gold hill, east of Pitkin. The Napoleon and Edna Draine were recently purchased by the Lanyon Zinc Co. The shaft on the Napoleon is down 200 feet.

Hinsdale County.

The Hanna M. & M. Co. expect to have their new 100-ton mill near Capitol City ready by Oct. 1. It is to be equipped with rolls, trommels, jigs, Wilfley tables and slimers, hydraulic classifiers and static electrical separators and is designed to turn out lead concentrates carrying gold and silver, copper concentrates carrying gold and silver values and a clean zinc product. The mine is developed by tunnels, the ore from the lower 850-foot tunnel being carried by a 5000-foot aerial tramway to the receiving house. From here it is to be carried to the crushers by a belt conveyor, the ore being hand-sorted to remove both high grade and waste. G. H. Martin is directing the work. J. W. Moffet is mill superintendent.

It is reported that the Max M. Co. intends putting in a mill near Capitol City. B. Geanneau is manager.——It is said that the Hinsdale T. & R. Co., which has succeeded the Henson Creek Lead M. Co., will resume work at its property, 13 miles above Lake City, with H. F. Wells of Boston, Mass., as manager.——The Pittsburg M. Co. have taken over the Wyoming, on Henson creek, 15 miles above Lake City, and, it is reported, will build a mill. The property has been worked by J. Schaffer.

Lake County.

At Twin Lakes work has been commenced on the Bull Hill properties belonging to the Fidelity Co. of Pennsylvania.——Work has been resumed by the Mt. Storm Co. on the Summit claim, on Red mountain, near Twin Lakes.

The bottom of the Penrose shaft atLeadville has been reached and a large station will be cut to accommodate two compound pumps that will have a combined capacity of 3000 gallons per minute, and this will more than suffice to keep the water under control. When the pumps are in, drifting toward the Coronado will commence, and when some distance has been gained the pressure of water at the Coronado will be lessened. The draining of this property means a great deal to the district, as it is now possible to sink any shaft in the downtown section without having to pump.——The Nil Desperandum shaft on Rock hill is down 740 feet, and after passing through the blue lime for 150 feet, the last shift in the shaft of 14 feet was sunk through a disintegrated mass of heavy mineralized matter.

Pueblo County.

It is reported that F. J. Hearne, president of the Colorado Fuel & Iron Co., plans to bring G. P. Harault from Paris, France, to show his process of smelting iron by electricity. It is said that by Harault's method iron ore containing any quantity of sulphur or phosphorus may be used for making steel, and that magnetic iron can be handled as easily as hematite.

San Miguel County.

Manager E. A. Taft of the Doctor Franklin syndicate operating in the Mount Wilson district, near Telluride, reports that he has eight men opening the road to the Silver Pick mill, so that the mill may be started after being repaired. The mine is still buried under the snow.

Summit County.

The Pennsylvania-Ohio mines at Argentine have put on a large force. The mill is running to its full capacity.——Manager E. McConnell of the Braganza mines has started work in their Warden gulch property, near Argentine.——Work is to be resumed at the Rothschilds tunnel, near Argentine. The bore is in over 3000 feet.

The Rose of Breckenridge is producing good zinc and lead ores from the main tunnel workings. The leasers will start shipments soon.——Boyce Bros. and G. C. Forsythe, operating the Waupeta property on Farncomb hill, near Breckenridge, have struck high-grade lead and zinc ore.——The mill at the Old Union Co.'s property near Breckenridge has received the necessary adjustment and alterations and has been started.——The Morning Star mine, on Baldy, near Breckenridge, is being developed by W. P. Condon and E. W. Shrock. ——Air drills have been put in at the King Solomon tunnel, near Frisco. The tunnel is in 250 feet.——Near Summit gulch, near Breckenridge, the Evergreen group is being worked under the direction of Theo. Knorr.

It is reported that after working for ten months on the Fountain lode on Farncomb hill, near Breckenridge, Boyce Bros. & Forsythe have found the vein.

E. Loring of the Hoosier Gulch G. M. Co. is directing lode and placer work at the Hoosier property at the Summit county base of Hoosier pass, near Breckenridge. Stouffer, Huntington & Bernatchie, with a pumping and hoisting plant, are sinking a shaft on a vein that runs through the placer.——H. T. Keltie of Joliet, Ill., president of the Washington-Joliet M. & M. Co., has been at Breckenridge inspecting the progress and development of the property. There is talk of building a new mill at the mine.——J. P. Howe, president of the Senator G. M. Co. and the Wonderful & London Placer Co., has been at Breckenridge from Boston, Mass., to examine the mines under the management of M. M. Howe.

Teller County.

Lessee Gillpatrick has opened up high-grade ore in the Accident mine of Gold Hill, Cripple Creek.——Superintendent L. Mac Cummings, of the New York group on South Straub mountain, Cripple Creek, contemplates putting in a 50-ton experimental cyanide plant preparatory to a 200-ton plant, if it proves successful in treating the new body of low-grade ore.——Airheart & Shepherd, lessees, on the Rocky Mountain, near the El Paso Con., on Beacon hill, Cripple Creek, after sinking 250 feet. have started a prospecting crosscut at the 85-foot point in the shaft.

Sinking has been suspended in the C. K. & N. on Beacon hill on account of the flow of water. The pumps have been closed and placed on the surface. Two weeks of hard pumping showed that the water was stationary. The C. K. & N. is the deepest shaft on Beacon hill from a point of elevation above sea level. The vein carries the water course and dips into the shaft 300 feet below the present drainage tunnel level. The El Paso adjoining will take care not to cut the C. K. & N. vein in its lower workings, and by remaining away from it will be able to continue sinking.

It is reported that $500,000 of the $750,000 needed has been subscribed toward driving the tunnel to drain the Cripple Creek district gold camp, by the mine owners of Colorado Springs and Cripple Creek district, including I. Howbert, president of the Portland G. M. Co.; W. Bainbridge, superintendent of the El Paso; A. E. Carlton, C. C. Hamlin, A. Holman of the Golden Cycle; J. W. Graham and E. M. De La Vergne. It is expected that work will be begun within ninety days. The new tunnel will have a total length of 27,140 feet and will drain the camp to a depth of 1500 feet. The tunnel will start at a point in the bed of Cripple Creek, 3 miles below the El Paso shaft. From the portal it will be driven to the El Paso shaft, a distance of 14,000 feet, thence north of east to the Vindicator property, a distance of 12,640 feet. This bore will cut the El Paso workings at depth of 1325 feet, the Elkton at 1680 feet, the Portland at over 2000 feet, and the Vindicator at over 2125 feet. The bore will be pushed from four working faces, including the main southern portal. The El Paso shaft will be sunk to the tunnel level and the bore started north from that point. An intermediate shaft will be sunk to the tunnel level midway between the El Paso and the main portal, from which point the tunnel will be driven both north and south. The plan now under consideration will carry the big bore across all of the known underground water courses, and it is believed will drain the entire section north of the tunnel.

Operations have been resumed on the Fluorine property on Copper mountain, Cripple Creek. The company recently secured assets of the Sioux Falls M. & M. Co. A cyanide mill has been started and is treating from fifty to seventy-five tons of ore a day.——The construction work on the cyanide mill of the Little Giant Co. in Pony gulch, near Cripple Creek, is nearly completed and it is believed that everything will be in working order by July 15.

Phillip Argall has been examining the Globe and Ironclad hill properties belonging to the Stratton-Cripple Creek M. & D. Co., to make a report of the feasibility of cyaniding the low-grade ore.——H. R. Richmond and associates, operating the Aileen property, on Guyot hill, Cripple Creek, under lease, are retimbering the main shaft from the surface down to a depth of 380 feet. When this work is completed they will commence to hoist ore.——Lessee Fogelman, who is operating the Reno Co.'s property on Womack hill, Cripple Creek, has opened several ore shoots between the surface and the 100-foot point.——Experiments have been made on ore from the San Juan, on Mineral hill, Cripple Creek, regarding cyanide treatment.——J. F. Hadley & Co., lessees on the Beacon Hill-Ajax property, Cripple Creek, have started sinking.

At Cripple Creek work has been resumed at the South Burns shaft of the Acacia Co. by the Exposition Mines & Leasing Co., lessee.——Interruption was caused by the appearance of water. Now that the water has seeped away sinking will be resumed, the intention being to add 200 or 300 feet to the depth of the shaft. The present depth is 265 feet.——It is reported that rich ore has been opened up by lessees between the third and fourth levels of the Doctor-Jack Pot mine at Cripple Creek. C. Vetter and associates are the lessees. —— D. Bernard, working the El Paso dump, Cripple Creek, has increased the force to eighteen.

IDAHO.

Blaine County.

The force at the Minnie Moore mine, near Hailey, has been reduced and the mill is being cleaned up preparatory to shutting down in accordance with new plans for the operation of the mine, which, from now on, is going to be worked partly by leasers and partly by day's work. The engineers, the sinking crew and the managing staff are to be retained, but in the stopes and where ore is expected to be found leasers will be given an opportunity to work.

Lemhi County.

The Gold Flint M. Co., whose properties adjoin the Gold Dust mines of Leesburg, announces the beginning of work for the installation of a 40-ton mill, which is to be in commission by October 1.

Nez Perces County.

B. B. Hans of New Orleans, La.; W. Harris of Alexander, La.; E. Enderle of New Orleans, La.; and C. F. Knoll of Bunkie, La., the four stockholders of the Idaho Placer & Quartz G. M. Co., have been in Lewiston arranging to start mining their placer claims on the Salmon river, near Forrest. Since October they have been working from 18 to 20 men on the flume, which is to be 4½ miles long. Hydraulic mining will be started with one stream.

Shoshone County.

It is reported that an independent smelter is to be built near Mullan.——The Sister M. Co. of Wallace proposes to sink a shaft 150 feet east of the main tunnel. A hoisting plant will be put in.

Hill Bros. of Carbon Center, near Delta, are putting up a building preparatory to using a gasoline engine to furnish power for their mine.——Geo. Busen and partner are cleaning bedrock, near Delta.——A 400-foot tunnel is to be run on the Wakeup Jim property, near Delta.—— The Golden Chest tunnel at Murray is in 1800 feet.

J. L. Safford, superintendent and manager of the Sampson M. & D. Co., has reports that the tunnel has reached the ledge. The Sampson group is on Big creek, near Wallace.——A. L. Thurston is preparing to start work on the Rough Rider group, near De Borgia.—— T. L. Greenough, of Larson & Greenough, owners of the Morning mine, has bought control of the Snowstorm mine, near Mullan, the only copper producing mine in the Cœur d'Alenes. During the year it has been worked under lease and produced $300,000 worth of copper. Ore has been extracted from the upper workings, the only portion of the mine which is leased. The lessees are J. H. Howard & Co. of Missoula. The lower workings have been under development by the owners and large bodies of low grade copper ore have been disclosed in both the upper and the lower workings.——The Headlight M. Co., which owns claims adjoining the Mammoth, near Wallace, will resume work.

KANSAS.

J. E. O'Neil, of Independence, vice-president and general manager of the Prairie Oil & Gas Co., says that the Standard Oil Co. has decided to resume work in the Kansas field and will complete the storage tanks in Kansas, construction of which was discontinued when the last Legislature was in session. At that time producers of oil under 30 gravity were notified that no more heavy oil would be taken and pipe lines to such properties were disconnected. O'Neil's order is to the effect that as soon as tanking can be built and other arrangements can be made, it is proposed by the Prairie Oil & Gas Co. to buy oil between 22 and 30 gravity, and so long as present conditions exist to pay 25 cents a barrel for it.

The Whiting pipe line has begun taking oil from the southern field. The line is not yet completed, but as it will require ten days to fill the pipe it is believed that it will be completed before the end of that time. It will take 150,000 barrels of oil to fill the pipe. In addition to this there is completed tankage along the route for 70,000 barrels more. The working capacity of this line is 18,000 barrels a day, but it will be some time before the line will take this amount, as several pumping stations have yet to be built. The Whiting line, constructed and owned by the Standard Oil Co., runs from the southern Kansas oil fields through Kansas City to Whiting, Ind.

MICHIGAN.

Houghton County.

The Baltic will have its permanent equipment completed at No. 2 shaft late this fall. The permanent hoisting engine is almost completed. Grading has just started and foundation material is now being delivered for the boiler plant at No. 2 location. Bids are being received for the 60-drill compressor for No. 2, which will have a capacity of 4000 cubic feet of air per minute. The drifts are being extended southward from No. 3 shaft to the No. 2 territory.——The permanent hoisting engine at shaft D of the Champion mine is completed. The Champion's experimental plant in the mill extension, in which a test is to be made in crushing the copper rock entirely by rolls, will probably go into service about Aug. 1. An increase in fuel economy and a reduction in tailing losses are hoped for.

The Calumet & Hecla is to operate another shaft on the Osceola amygdaloid lode. The unwatering of No. 16 shaft is progressing for this purpose, while on surface important improvements and overhauling are going on in the shaft rock house. The shaft, which is less than 500 feet deep, was filled with water to within 100 feet of surface. There are also two levels, each drifted 600 feet. The levels are 8x8 feet and the shaft is three compartment. The water is being raised entirely by pumping. One pump is placed in the skip and is thus lowered as the water goes down. This pump lifts the water to an established pump station at the first level, and a fixed pump there raises it to the surface. The work in No. 16 shaft, like that which has been progressing in No. 13

shaft on the Osceola lode for about a year, is for exploration and a thorough mill test.

MISSOURI.

Under the supervision of H. F. Bain of the U. S. Geological Survey, G. H. Girty will study the stratigraphy and paleontology of carboniferous formations in southwestern Missouri, with reference to associated lead and zinc. Topographic work in the Forsythe and Shelbyville quadrangles will be in charge of H. Munroe, assisted by C. G. Anderson and G. L. Hoopes.

Jasper County.

The Joplin Commercial Club is agitating the need of protection from British Columbia zinc ores, that have been coming into the country the past ten months duty free. It is trying to secure a tariff on zinc ore. The law applying to the importation of ores is an old one and imposes an ad valorem duty of $\frac{1}{2}$ of a cent a pound on lead ores. At the time of its imposition its purpose was to stop the importation of lead ores from Mexico. The amount of zinc at that time was very small and did not represent the industry it does to-day.——The lease of the Helen Lead & Zinc Co. at Chitwood has been sold for $80,000 to the Pittsburg-Missouri Zinc & Lead Co. by L. P. Cunningham. There are eight operating mills upon this tract.

Regarding mines, near Joplin, the News Herald says that Batten & Co. have a shaft down 80 feet on the Rex M. Co.'s land.——After being idle several months, the old Sherwood mill has resumed operations.——The Lilly M. Co.'s new mill in the Sherwood district has begun operations.——W. Leffen and partners have made a good strike of lead ore on the Riseling land.——P. E. Campbell & Co. have let a contract for 1000 feet more drilling on the Amazon land.——The Searcher Dev. Co. is preparing to sink a shaft on a lead prospect on Turkey creek.——J. H. Cook, of Carthage, has opened up a good prospect on the Reynoldsville land, south of Reeds. ——Flock Bros. of Villa Heights are mining at a depth of 20 feet on the Rex M. Co.'s land.——The Dickerson land, 1½ mile north of Joplin, is being drained by powerful pumps. P. Hennessey has taken a lease on twenty acres of the Rex M. Co.'s land and is sinking a shaft.—— The Smith-Kernohan Co. of Cleveland, O., has secured a lease on ten acres of the Cissna land.——The mining land at Lehigh, south of Carl Junction, is being put in shape for resumption of mining operations. —— The Providence M. Co. are sinking a shaft on the Lyon M. & D. Co.'s land at Porto Rico. —— C. Rinehart of Carthage is manager of a company that is operating on the Show Me mill and lease on the Bloomington M. Co.'s land. —— S. B. Rauch and L. Casey, who are working a two-lot lease on the Missouri Lead & Zinc Co.'s land, southeast of Joplin, are cutting a prospect drift at a depth of 100 feet.

Newton County.

The La Sallier concentrating plant on the Allen land at Spring City is to be started July 1.

MONTANA.

Broadwater County.

Work on the Park and New Era, near Hassell, is under the direction of Manager Atwater. The shafts and upper levels have been unwatered and connections made with the lower tunnel. A cyanide plant is contemplated, in addition to the 100-ton concentrator, which will be started as soon as the lower and upper workings are connected, so that ore can be taken to the mill at low cost.

Fergus County.

A large body of ore is said to have been made on the Bullard property, at Kendall, being worked by the Queen G. M. & M. Co., F. S. Weidenborner, president and manager.——P. W. McAdow will start work on the Alpine, near Maiden.

Jefferson County.

Work has been started at the Huot mine, near Basin, by G. Freeburg and P. Dowling.——G. W. Winter is developing a silver claim near Clancy.——The Morning Star mine, 10 miles north of Basin, is being operated by Waldie, Jackson and Bullock under lease and bond from Hieber Bros. This property has been idle for several years.——W. F. V. Young of England has succeeded T. Clearage as manager of the dredge on Gold creek, 30 miles northwest of Basin. The boat is now in operation.

Lewis and Clarke County.

G. H. Babcock has secured options on practically the whole of the Seven-Up-Pete district, on the main range of the Rockies in the gold belt that extends from Helena through the Marysville, Gloster, Jay Gould and Stemple districts. The properties acquired are the Rover, Columbia, Donnely, Howe, Hokan Johnson.——The Red Bird Co. of Helena has sunk another 100 feet on the incline of the Red Bird and is drifting to the vein. The company is also developing three claims which join their Reliance mine in High Ore gulch. There is a tunnel 140 feet and a shaft 50 feet deep on the properties.

S. T. Hauser reports that negotiations for building of another power dam on the Missouri river have been completed, and that the work will be commenced at once. The new dam, which will add 10,000 H. P. to the power already furnished by the Missouri River Power Co., near Helena, will double the cheap power available. The new organization is the Helena Power Transmission Co. The new dam and plant will be located at Stubbs Ferry, 16 miles from Helena. Power will be furnished at from $35 to $50 per year per horse power.——Among the contracts for power is that of a Cleveland syndicate which has secured 3000 H. P., and will build at Helena an electric reduction and refining plant.

Silver Bow County.

(Special Correspondence).—The mining companies of Butte have completed their annual reports to the assessor for the purpose of taxation on net earnings. The reports show a total in net earnings of $9,942,310.45, an increase over last year of $2,596,701.11. Of the increase $2,452,218.98 is credited to four amalgamated companies and $87,726.16 to the United Copper companies. The Heinze or United Copper companies reported the following net earnings: Montana Ore Purchasing Co., $335,573.27; Hypocka M. Co., $96,995.57; Guardian M. Co., $117,739.29; Corra-Rock Island Co., $56,644.43; total, $606,952.56. Last year the total net earnings of the Heinze companies were $519,226.40. The following items are from the reports for comparison: Tons of ore extracted, Boston and Montana Co., 1,138,307; Anaconda, 1,473,644; Butte & Boston, 260,433; Parrot, 167,963; Trenton, 150,296; Washoe, 102,941; Montana Ore Purchasing, 170,169; Hypocka, 77,103; Guardian, 43,591; Corra-Rock Island, 122,697; Original, 343,850; Speculator, 112,940. Gross yield per ton—Boston & Montana, $12.86; Anaconda, $9.36; Butte & Boston, $7.42; Parrot, $8.63; Trenton, $5.64; Washoe, $10.66; Montana Ore Purchasing, $8.59; Hypocka, $8.35; Guardian, $9.30; Corra-Rock Island, $7.36; Original, not given; Speculator, $8.43. Cost of reduction per ton—Boston & Montana, $2.21; Anaconda, $3; Butte & Boston, $2.45; Parrot, $2.74; Trenton, $2; Washoe, $3.79; Montana Ore Purchasing, $2.65; Hypocka, $2.68; Guardian, $2.59; Corra-Rock Island, $2.53; Original, $3.02. Cost of extraction per ton —Boston & Montana, $2.91; Anaconda, $3.51; Butte & Boston, $3.31; Parrot, $3.75; Trenton, $3.02; Washoe, $4.29; Montana Ore Purchasing, $3.72; Hypocka, $4.17; Guardian, $3.76; Corra-Rock Island, $4.11; Original, $3.31; Speculator, $5.85. Gross proceeds—Boston & Montana, $14,634,923.46; Anaconda, $13,787,345.07; Butte & Boston, $1,932,837.12; Parrot, $1,449,851.37; Trenton, $847,421.35; Washoe, $1,097,018.79; Montana Ore Purchasing, $1,461,241.20; Hypocka, $643,887.15; Guardian, $405,527.07; Corra-Rock Island, $902,264.91; Original, $2,599,615; Speculator, $952,084.20. Net proceeds—Boston & Montana, $5,855,620.07; Anaconda, $2,259,693.73; Butte & Boston, $178,712.81; Parrot, $328,106.69; Trenton, $70,110.22; Washoe, nothing; United Copper, $606,952.56; Original, $349,387; Speculator, $291,385.20; miscellaneous mines, $2,342.17.

Butte, June 26.

Teton County.

The Midvale Lubricating Oil Co. has been incorporated to develop the oil fields around Lubec. The company has 1600 acres. M. L. Bevins of Spokane, Wash., is president, T. H. Thompson vice-president, G. P. Mulcahy secretary.

NEVADA.

A detailed economic investigation of the Goldfield mining district and reconnaissance economic and geologic surveys of other districts in southern Nevada will be made by J. E. Spurr, assisted by G. H. Garrey and F. Hewitt A geologic reconnaissance of quadrangles in southern Nevada will be made by S. H. Ball, under the supervision of Mr. Spurr.

Lincoln County.

(Special Correspondence).—Ore high in silver and copper from the Tecopa and Resting Spring mines is being hauled to Sandy preparatory for shipment to smelter.—— The Keystone mine and mill are running steadily on high-grade gold ore. Thirty-five men are at work under management of M. R. W. Rathbone. —— H. Hardy of Salt Lake City, Utah, operating the Chiquita, 5 miles from Sandy, has made a rich strike on the property.

Sandy, June 28.

The Searchlight M. & M. Co.'s new 15 H. P. gasoline hoist is being put in at Searchlight. The shaft has been straightened and a station cut at the 250-foot level.—— The G. M. Rose cyanide plant at the Southern Nevada at Searchlight has been started. Eight of the tanks have a capacity of fifty tons each, and by loading and unloading two each day 100 tons will be handled daily. It is estimated that it will require six months to clean up pile of tailings.——Prospect shafts are being sunk on the X-Ray group, near Searchlight, to determine the best location for a deep working shaft.——Work has begun on the Empire crosscut tunnel, near Searchlight, which, when completed, will have a length of 500 feet. Eventually the mine will be worked by this tunnel.——The El Dorado M. Co. has set up a whim and is sinking the main working shaft, near Searchlight, to the second level.

The Boston & Pioche, at Pioche, are pushing the North Pole tunnel, being in 330 feet, and will start a permanent deep shaft on the Boss soon.——The Nevada-Utah is putting in a hoist at Meadow Valley No. 5, a three-compartment shaft, and will sink to the 2000-foot level.——The Abe Lincoln, at Pioche, has thirty-five men at work and intends to do considerable development this winter in addition to running the mill.

The new schedule of rates on ore shipments from Los Vegas to the smelters in Salt Lake valley is looked upon with favor by miners and smeltermen and will tend to aid development in the Bullfrog district. The rates over the Salt Lake Route are as follows:

Ore Value.	Rate Per Ton.
$25	$ 5 25
35	5 75
50	8 50
100	11 00
200 to 300	14 30

Add 2% for all ore above $300 in value.

Nye County.

The Western Ore Purchasing Co. has commenced work on the sampling plant they are to construct at the company wells, 12 miles from Tonopah, on the Tonopah Railroad. Manager Chas. Snyder states that as soon as the plant is completed fifty men will be put to work.

G. D. Johnstone, in the Bullfrog Miner, gives the following information regarding the mines at Crystal Springs, 7 miles north of Beatty: At the Gold Coin group of six claims one man is employed. Will let contract to two men for 100-foot tunnel. The Mackay-Graham syndicate of Denver, Colo., has bought the property for $10,000. Grape Vine group of five claims is prospecting with two men. Bond & Gaut have three claims. They have opened a pay chute, crosscutting the ledge on the surface. The Mayflower ledge has been opened up by Duvahl on Duvahl mountain. The Gold Reef claims are working two men. The Tripolite claim has one man at work.

NEW MEXICO.

A reconnaissance economic investigation of mining districts will be made by W. Lindgren of the United States Geological Survey, assisted by L. C. Graton. A reconnaissance investigation of the Gallup coal field, in the northern part of the Territory, will be made by F. C. Schrader, under the supervision of M. R. Campbell, assisted by M. K. Shaler. A geologic reconnaissance of the northwestern part of the Territory will be made by Whitman Cross, assisted by W. H. Emmons, L. H. Woolsey and G. F. Kay.

OREGON.

Baker County.

The Yankee Girl G. M. Co. has been formed, with principal offices at Wheeling, West Virginia, to work the Yankee Girl and May Girl claims, near Sumpter. A hoist and pumps will be put on the property and the shaft continued from the 40 to the 100-foot points. Guy Pierson is superintendent and W. C. Fitzsimmons, consulting engineer.——Gilkey & Kershaw have given control of the Belmont mine on Vincent creek, near Tipton, to A. Mohr and O. Herlocker of Sumpter.——It is reported that Abel & Rose of Sumpter have located claims, near the Belmont, from which they took $2040 in nine days.

The Granite Mountain G. M. Co. is prospecting on their property, near Weatherby.——M. N. Thompson is manager.——It is reported that dredging is to be resumed in Burnt river, near Weatherby.——At the Indiana mine, 28 miles from Baker City, J. W. Messner intends to explore the promising copper deposit.——A strike is reported in the Esmeralda mine, 2 miles from Bourne, 150 feet from the tunnel portal. W. B. Robinson, D. S. Kinsey, J. W. Gray and J. C. Shea of Baker City and W. P. Kinsey of Portland are owners.

Grant County.

A hoist, boiler and engine have been put in at the Gem mine, in the Susanville district. J. Dunstan is superintendent and will put on a large force. The shaft will be continued 300 feet from its present depth.

A hoisting plant is being put in at the Gem of the Mountains, near Susanville, and a mill is to be put up to treat the ore.

Josephine County.

Manager A. F. Hoofer of the Mt. Pitt mine on Jump-off-Joe, near Grants Pass, plans to haul ore to the smelter being built near Grants Pass, using a traction engine and a stationary engine and cable for the grade from Jump-off-Joe to Evans creek divide.——H. B. Nye of Medford has leased the Bertha quartz mine, on Foots creek, near Gold Hill, from Young & Meyer.

SOUTH DAKOTA.

Lawrence County.

It is reported that the Golden Reward M. Co. is considering building a cyanide plant near Terry.——The Big Lead Company, operating near Roubaix, has struck rich ore. One shaft has been sunk 200 feet and a second is being sunk to explore the vein. The company intends building a 100-ton amalgamating and cyanide mill.—— W. L. McLaughlin, of the Horseshoe Co., has settled with the insurance adjusters for the recent loss of the Mogul mill, for $232,542.53.

Pennington County.

Gill, Weber & Leisy of Cleveland, Ohio, have purchased wolfram mines from N. Ervin, W. L. Miner, J. W. & N. J. Smith, through J. Truax of Hill City. The property purchased includes sixty acres, 2 miles east of Hill City, on which a strong vein of wolfram-bearing ore has been opened. The new owners intend to at once begin work and prepare the mine for production.——Work at the Dakota-Calumet, near Hill City, has been suspended, owing to the inflow of water which could not be handled with the equipment. A boiler was purchased of C. E. McEachron of Hill City, and a new Cameron pump ordered from Denver. This machinery will be put in and sinking resumed.——Geo. Bain, superintendent of the Walton M. & M. Co., which has taken over the Tea and Dolcode properties, near Hill City, has men at work putting in new machinery and a new hoist building.

UTAH.

Beaver County

(Special Correspondence).—The Horn Silver mine at Frisco is operating with forty to sixty men. The mill, which has been handling zinc ores from the mine, has not been able to run for some time on account of the water supply being short. It is understood arrangements are being made for water. Several properties are being worked in the vicinity.

Frisco, June 26.

Juab County

The shipments of ore from the mines of Tintic district during the week ending June 24 consisted of 105 carloads as follows: Eagle & Blue Bell, 11; Yankee Con., 6; Centennial-Eureka, 45; Bullion-Beck, 4; Gemini, 7; Ajax, 2; Carisa, 2; Grand Central, 4; Lower Mammoth, 1; Mammoth, 8; Victoria, 4; Victor, 2; Swansea, 6; Tetro, 2; Godiva, 1. Total, 105. Uncle Sam mill, 2 cars of concentrates.

The Raymond and Illinois mines at Tintic have been united and will be worked by the Raymond-Illinois M. Co. J. C. Sullivan is president and general manager; J. D. Woods, vice-president, and J. C. Lynch, secretary and treasurer. It was decided to proceed with the exploratory work at a depth of 1500 feet in the shaft in Raymond territory, and to run north and south in the ledge.

The management of the Grand Central mine at Eureka has made connection with the main ore-bearing channel, off the 1300-foot level. C. E. Loose is manager at the mines.

Salt Lake County.

C. H. Doolittle, of the Bingham & New Haven of Bingham, and the Utah & Eastern, operating the Dixie mines and smelter of St. George, says that shipments will be increased as soon as the aerial tramway, which will span a distance of 4700 feet between the mines and receiving station on the line of the Copper Belt railway, has been completed. Work will be started in July to undermine that portion of the ground which recently caved in at the Dixie mines, and to drive an 825-foot tunnel. To make this connection, the furnaces of the smelter will remain idle until it is accomplished. An air compressor with machine drills will be put in.——The

United States M. Co. has decided to extend the Niagara tunnel, from the 2500-foot station, to open up the Galena mine at Bingham.——W. J. Craig, manager of the Kennebec mine at Alta, will drive an intermediate tunnel which will tap the ore-bearing channels in the Reed & Benson lode at a distance of 400 feet from its mouth.

Sevier County.

Secretary M. F. Murray, of the Franklin syndicate in the Ohio mining district, near Richfield, reports that the new compressor at the mouth of the Franklin tunnel runs well. Operations will be confined to the Franklin tunnel, which is in 1000 feet. O. Larsen is superintendent.

Tooele County.

(Special Correspondence).—Near the head of Soldier Bridge canyon, at the property of the New Stockton M. Co., the work is being done under contract. The station at the 850-foot level has been completed and drifts started from this level. They claim to have four ore bodies on the east and three to the west of the shaft. A new hoisting engine and air compressor will be put in. A 75-ton concentrating mill near the shaft handles the product from the mine. Ore is not being taken out at present, hence the mill is not operating, but they expect to start taking out ore and run the mill in a short time. H. D. Trenam is superintendent.——Work is being pushed as rapidly as possible in the Honerine tunnel. When completed this tunnel will be 200 feet below the 1100-foot level of the Honerine shaft. Ore is not being broken in the mine at present and no ore is being taken out of the mine except as they cut through same. Development work is going ahead in drifts from the shaft. The tunnel is being worked both from the tunnel entrance and from the shaft. The tunnel will be used for draining the ground and for transporting the ore to the mill located at the tunnel entrance. The tunnel will be about 2 miles long when completed. There is 1100 feet farther to be driven. New shaft buildings have been erected at the mine since the fire several years ago.——On the east side of Tooele valley and 1 mile from Stockton is the 500-ton Honerine mill, handling the dump from the old mill of the Honerine Co., as well as all the ore from the Honerine mine. A spur from the San Pedro, Los Angeles & Salt Lake Railway runs to the mill. The power plant at the mill consists of Rand compressor, four boilers, engine, pumps, dynamo, etc. The tailings dump which is being treated in the mill is hauled about ¼ mile and dropped into the tunnel through an air shaft, and from there trammed to the mill by mules. The ore is taken from the ore bins in the mill onto a conveying belt, thence to the crusher, then elevated to a conical screen of ¼-inch mesh, the oversize going through dry rolls. The whole product goes to the top of the mill and is sampled by means of automatic samplers. The mill is automatic throughout and contains three Huntington mills, one Chilean mill, twenty-three Wilfley tables and three Wilfley slimers, besides jigs and trommel screens. The Sherman tank system is used. This system is composed of seven tanks.

Stockton, June 26.

Utah County.

G. & F. C. Tyng, operators of the Wyoming mine, are hauling ore from the mine to American Fork to be shipped to Salt Lake smelters. The 539-foot tunnel which has been completed will facilitate the handling of the ore.

Weber County.

(Special Correspondence).—The Napoleon - Maghera mine, in the Sierra Madre mountains, 12 miles north from Ogden, is being developed by Don Maguire, manager of the property. Excellent values have been obtained. Two tunnels are being driven into the property, which carries gold, silver and copper.——The Santa Maria group is being developed by the same party in the same neighborhood. The tunnel is in 500 feet and it is expected the contact will be cut in the next 100 feet. Work is being done under contract. Dirt assays $6 in gold and 3% to 10% copper.

Ogden, June 26.

WASHINGTON.

Whatcom County.

(Special Correspondence).—At Nooksack Falls, above Excelsior, the Bellingham Bay Improvement Co. will put in a power plant of 2000 H. P. The Post-Lambert Co., near Excelsior, began operation with a 10-stamp mill in July, 1903, and now has fifteen stamps. A tramway will be built this summer to convey the Lulu ore to the mill. The Great Excelsior, near Mt. Baker, is equipped with twenty stamps, a roller mill, regrinders, fifteen concentrators and an electric light plant. Three stopes have been opened up and forty-five tons of ore are milled daily. When the new machinery is in working order this will be increased to 100 tons, says President T. P. Sanders. The Nooksack, on Sumas mountain, has put in a 200-ton cyanide plant, which is expected to be in operation in a short time. In the Baker district, the Red Mountain people plan to put in a 10-stamp mill this year. On the upper level 180 feet of drifting has been done and a shaft sunk. On the lower level 250 feet of crosscutting, 110 feet of drifting and 100 feet of raising have been completed. The Gold Basin has two fissure veins 400 feet apart and three smaller ones. Tunneling and drifting will be pursued this year and, if possible, a stamp mill will be put in by J. O. Carlisle. At the Goat Mountain property (free milling) a 5-stamp mill will be put in this year, says Manager Blondin. The First Chance will put in machinery next year and power will be secured from the Nooksack Falls electrical plant. The leading mines in the Slate Creek district are the Eureka, Mammoth, Chancellor and North American. With the exception of the Chancellor, all of these have stamp mills, although the ten stamps of the North American have not yet been placed. The Chancellor G. M. Co. is considering putting in ten stamps. The Granite Creek G. M. Co. is the only incorporated placer concern operating in the district. Hydraulic machinery to cost $15,000 will be put in this summer.

Bellingham, June 27.

Snohomish County.

It is reported that machine drills and a concentrator are to be put in at the Buckeye mine, near Index.——The Bunker Hill concentrator at Index will be run day and night after July 4. Concentrates are shipped to the Everett smelter. V. V. Clark is superintendent.

Stevens County.

The Velvet mine and concentrator, on Sophie mountain, 12 miles from Northport, is to be started up.——The Blue Bell, on the same mountain, has 800 feet of tunnel and will continue until the ore body is cut.——L. Bobo has started work on mines adjoining the Blue Bell.——The George Foster galena mine, on Deep creek, near Northport, has been taken over by Eastern parties, who have started work.——The Copper King mine, at Chewelah, is shipping regularly to the Northport smelter. The Second Relief mine, near Erie, B. C., is a new shipper to the Northport smelter.

FOREIGN.

AUSTRALIA.

Victoria.

(Special Correspondence).—The deep gravel channels of the Ballarat region which have been worked more or less extensively in the past, but on which mining operations practically ceased when the heavy flows of water were struck, have been under investigation by Bewick, Moreing & Co. of London for several years past, and bore holes sunk to determine the course of these channels and their probable value in gold. It having been found impossible to drain the channel by ordinary methods, a shaft was sunk in the bedrock outside the rim of these ancient buried channels, which in many respects resemble those of California, and drifts run underneath the gravel. For many months an average of 20,000,000 gallons of water have been raised daily without in any way decreasing the flow of water, but the pressure has been reduced from nearly 200 pounds per square inch to about 35 pounds, and this is reported constantly decreasing, so that in time it is hoped the water will have been drained from this underground reservoir, when it is thought that the water problem will practically have been solved, as the rainfall in the district is very light. The gravels are known to be rich in gold, and when the water is under control the mining industry in Ballarat will no doubt receive an impetus which nothing else could give it.

Ballarat, May 20.

CANADA.

BRITISH COLUMBIA.

Boundary District.

G. W. Cornish has bonded the Capital Prize, near Greenwood, and will commence development work.——The unwatering of the Jewel has been finished and the engineers of the Le Roi No. 2 have sampled the mine. Until such time as a decision has been made as to purchasing, the mine will be kept clear of water.——On the Golconda in Deadwood the long tunnel is in 550 feet.——Water is being kept out of the Brooklyn and Stemwinder mines, pending examination.

Ore shipments from Boundary mines for week ending June 24 were: Granby mines to Granby smelter, 12,518 tons; Mother Lode to British Columbia copper smelter, 3584; Mountain Rose to British Columbia copper smelter, 264; Emma to Nelson smelter, 331; Oro Denoro to Granby smelter, 132; Bonnie Belle to Trail smelter, 20; Skylark to Granby smelter, 30; total for week, 16,879 tons; total for year, 442,034 tons. Boundary smelters this week treated: Granby smelter, 12,660 tons; British Columbia copper smelter, 3935; total for week, 16,595 tons; total for year, 453,945 tons.

According to the report of M. M. Johnson, who has recently examined the mines and smelting plant of the Montreal & Boston Con. M. & S. Co., near Greenwood, the property consists of one smelting plant at Boundary Falls and mineral claims and fractions of other claims in various parts of the Boundary district. This plant has two furnaces, 40x176, with a daily capacity of 300 tons. Three directly connected Connersville blowers, one 7x12 steam locomotive, slag cars, sampling mill with crushers and rolls, assay office and laboratory complete the outfit. Steam is the motive power. The mineral claims are as follows: At Phœnix are the Brooklyn, Idaho, Stemwinder, Standard, Montezuma and Rawhide; at Wellington are the Athelstan and the Jack Pot fraction. The Summit camp contains a three-fourths interest in the Mountain Rose and one-half of the Lancashire Lass. The Deadwood camp contains the Sunset, C. C. D., Crown Silver and Morrison. The cost of freighting the ore from the Phœnix and Summit camps via the Canadian Pacific Railroad is 30 cents a ton and from the Deadwood camp 17 cents a ton. The Athelstan is not connected with the railway. The Brooklyn lode has been developed to a depth of 350 feet and has 3500 feet of underground workings; the average sample taken from this mine represents the group: Copper, 1.43%; gold, $1.32; silver, 25 cents per ton. There are 260,000 tons of ore available for the smelter, which at current prices has a gross value of $5.86 per ton. The diamond drill indicates that there is an equal amount of ore below the developed ground. The Stemwinder is developed to a depth of 125 feet, but sufficient work has not been done to indicate the tonnage. Samples show: Copper. 1.4%; gold, $1; silver, 25 cents. The Idaho shows surface indications of the same body that is being worked in the Granby. The Rawhide has 600 feet of underground workings at a depth of 180 feet. Average assays show: Copper, 1.4%; gold, 90 cents; silver, 25 cents; available tonnage, 230,000 tons; prospective tonnage, 1,000,000 tons. The Mountain Rose vein has been explored for 125 feet; ore contains 40% to 50% iron, 20% sulphur and about $1 in copper, gold and silver. It is valuable only as a flux. The Lancashire Lass has a shaft 50 feet deep, is stripped for a distance of 500 feet and is of the same quality as above and has from 2000 to 3000 tons on dump. The Athelstan is merely a prospect. The Sunset has a shaft 200 feet deep; no drifting below 100 feet. The equipment at the mine is not of the proper type or of sufficient power for economical work. In order to put the mine on a production of 1500 tons a day and keep the cost of production down to a point that would make the operation profitable, there should be an expenditure of $250,000 for an additional furnace, converting plant, electric power equipment, compressor and mine development.

East Kootenay District.

The No. 1 lead stack of the Marysville smelter has been blown in with satisfactory results. Power for all purposes is derived from four 48-inch Pelton wheels operating under a head of 325 feet, the water being delivered to the nozzle from a 24-inch steel pipe. Steel cable transmission from the Peltons delivers the power to all parts of the works. The ore is dumped from ordinary cars into the bins of the sulphide and sampling mills, and from there runs across to the storage bins. From these latter it goes on a belt conveyor, and by an ingenious system of short levers any particular furnace can be fed from the same conveyor. The roasting plant consists of four hand-stirred roasters and two of the new Haberlein rotary pattern. The latter are circular in shape and are peculiar in that the floor or hearth which carries the ore revolves on a central axis, and the ore is worked from the central feeding point to the circumference by means of fixed rakes. The roasted ore, on reaching the outer edge of the hearth, is discharged through three apertures, one portion being red hot and another portion being comparatively cool. The cooler ore goes to the upper floor of the conveyor building and the hot portion is run direct in on the perforated bottom of the Haberlein converters. The cold ore is run down over the hot and the blast is turned on, burning out the sulphur and leaving mass in a spongy, porous condition. When the blast is turned off the converter is inverted and the mass is shot out onto the cooling floor. The roast is then run across to the assembling house, where the furnace charges are made up. The ordinary smelter cars carry the charges to the feeding floor; but here, as elsewhere, hand labor is eliminated as much as possible, as the cars ascend and descend on a chain conveyor. W. G. Smith is manager of mine and smelter.

Nelson District.

The Ivanhoe mine has closed down indefinitely. The resignation of J. B. Kendall as manager has been accepted.——A new vein has been discovered on the Rambler-Cariboo ground, near Nelson, of which W. E. Zwickey is manager.

Ontario.

W. G. Miller, provincial geologist of Ontario, reports that no white arsenic was produced in Ontario during 1904. The only producer in previous years was the Deloro mine, Hastings county, and this mine has been closed for more than a year on account of a strong flow of water in the 500-foot level. Operations will probably be begun again here soon. Some mispickel concentrates were produced in the treatment of gold ores at the Atlas arsenic plant, which adjoins the Deloro, but these concentrates were not roasted. The new arsenic districts of the Province which are being developed are near Lake Temagami and Cobalt Station on the line of the new Government railway, the Temiskaming and Northern Ontario. Lake Temagami lies 300 miles north of Toronto by rail, and Cobalt Station is 25 miles farther north. There are two deposits of mispickel being developed near Temagami. The deposits in which the mineral is found are rather irregular in form, the mineral occurring in bunches or masses and more or less disseminated through greenstone and related schists of the Keewatin system. At Cobalt Station the arsenic-holding ores consist essentially of arsenides of cobalt and nickel, such as smaltite, niccolite, chloanthite, etc. Associated with these ores is much native silver, together with several silver minerals, such as pyrargyrite, argentite, dyscrasite, etc. Native bismuth is found in all the deposits, together with tetrahedrite and other ores, a similar assemblage of minerals to that of the well-known Saxon deposits. It is interesting to find that the iron arsenides of Temagami are auriferous, gold occurring in commercial quantities in these ores; the nickel-cobalt arsenides of Cobalt Station are argentiferous and contain no gold. The latter deposits occur in the form of distinct veins, which cut the almost horizontally lying fragmental rocks of the lower Huronian, which here consists of conglomerates, breccias, slaty graywackes, etc., in an almost vertical direction.

Rossland District

It is reported that the Gooderham-Blackstock Syndicate has sold out its control in the War Eagle, Center Star and St. Eugene to a syndicate headed by Osler & Matthews of Toronto, who have associated with them in the deal other Montreal and New York capitalists. The reason for the sale is the death of G. Gooderham and the illness of T. G. Blackstock. Osler & Matthews are directors of the Canadian Pacific Railway, and it is presumed from this that the C. P. R. R. and the Trail smelter have an interest in the deal.

The shipments for the week ending June 24 were as follows: Le Roi 1930 tons, Center Star 1770, War Eagle 1000, Le Roi No. 2 90, Jumbo 300, Spitzee 30, Gopher 60, Homestake 30; total, 5210 tons; total for the year to date, 162,404 tons.

Slocan District.

Regarding the Highland mine, near Ainsworth, Norman Carmichael manager, the report of the British Columbia Minister of Mines says that the Highland ore is quartz carrying galena, with low silver values and small amounts of pyrite, pyrrhotite and zinc blende. The galena carries ½ to ¾ an ounce of silver to the per cent of lead, the concentrates running 70% lead and 20 to 25 ounces silver. The concentration ratio is 1 to 7 or 1 to 10. The galena values are all that are saved. The mine has been opened by tunnels to a vertical height of 500 feet. The ore from all the workings is delivered by chutes to the lowest level, whence it is trammed to the upper terminal of the aerial tramway which carries it to the concentrator on Kootenay lake. The concentrator is run by water power under a 450-foot head, a 48-inch Pelton wheel being placed on the top floor and the waste water used for concentrating. The crushing is done by a Gates crusher and three sets of rolls. The coarse rolls run at eighty-five revolutions, the medium at ninety-five and the fine at 105 per minute. The concentrating is done by two coarse jigs, three 3-compartment and two 4-compartment jigs and six Wilfley tables, with hydraulic classifiers, settlers, etc. The extraction is 80% to 85% assay value. For 39,148 tons treated, debiting the value of the new wearing parts at the beginning

and crediting the estimated value of the wearing parts partially worn, the cost of crushing and concentrating was $0.1425 per ton, divided as follows: Crusher $0.0195, rolls 0.0495, trommels 0.0191, jigs 0.0091, launders 0.0066, elevators 0.0096, belting 0.0074, dynamo 0.0029 and general 0.0188.

Manager H. M. Stevenson will resume work at the Highlander mine, 2 miles south of Ainsworth. The group includes the Little Diamond, Black Diamond, Highlander, Eagle and Ivanhoe claims, and extends from the shore of Kootenay lake to the top of the hill. To cut these leads at a depth of 1000 feet below the old workings, the company in 1899 started a crosscut tunnel from the Eagle claim, 300 feet above the lake level. After running 2610 feet it has cut the Highlander and Black Diamond veins.——Work is to be resumed by A. Smith on the Surprise mine at McGuigan. It is the intention of the owners to run a long tunnel from the south side of the hill to tap the lead at a depth of 700 feet below the present workings, which are now down 300 feet.

BOLIVIA.

The British Consul at La Paz reports that only a part of the Bolivian mines are worked at present, owing to difficulties of transport and communication with the coast. Bolivia is said to occupy the third place in the world's production of tin—but if her output continues in the same proportion as of late years she may occupy the first. Silver mining, which in former years was the chief industry, has greatly decreased of late, partly on account of the fall in value in European markets and also owing to the mines being more or less worked out. Copper is almost exclusively produced from the Corocoro mines. Gold is also found in Bolivia, but with the exception of the works at San Juan del Oro and Chuquiaguillo, there are no other establishments worthy of mention. The latter place is 3 miles from La Paz. The amount of tin exported from Bolivia during 1904 was 45,597,967 pounds, representing an official value of £1,275,944. Sulphur is found in Tomina and Acero (department of Chuquisaca), Carangas (department of Oruro), Sililica, Chayanta, Atacama, Lipez and Tacora. Pure sulphur in Carangas, Lipez, Atacama, Chayanta, Porco and Tomina. Antimony in Sicasica, Ayopaya, Tapacari, Arque, Pisacoma, Guanuni, Antequera, Ichucollo (these last four in Oruro), Poopo, in North and South Chichas, Pacajes, Porco, Palca and La Paz. Arsenic in Choquelimpia (Carangas), Chayanta, Lipez, Atacama and Porco. Asphaltum in Concepcion and Tomina (Tarija). Quicksilver in San Jose (Chiquitos–Santa Cruz), near the city of Potosi, Chayanti, Huarina (Omasuyos), Challatiri (Potosi), Moromoro (Chuquisaca), San Javier (Chiquitos), Santa Rosa and San Jose, Calamarco (La Paz). Coal in the neighborhood of Sucre, Tarabuco, Chorrete (Aziro), Tomina, Sicasica and Pacajes, around Lake Titicaca, Mojos, River Tuiche (Caupolican), Buena Vista (Santa Cruz). Copper in Yungas and Yamparaez, Cinti, Tomina and Azero, Tahuapalca (La Paz), Corocoro, Collocollo, Poopo, and the district of Oruro, North and South Lipez, Atacama, Tarija, Abilez, Osiloque, Suapi (Lipez), Jura (Porco), Colcha, Huatacondo, Esmoraca, Tarabuco, Macha, Paria, Chayanta, Turco, Curaguara (Pacajes), Ulloma, Cusillomayo and Porco (province of Potosi), Turco (Oruro). Tin in San Javier (Santa Cruz), Yamparaez, Oruro district, Poopo, Pisacoma, Guanuni, Chayanta, Carabuco (Omasuyos), Colquiri (Oruro), Ampaturi (La Paz), Milluni, Vilaque (La Paz river), Huayna-Potosi, Chorolque, Maragua, Ocuri (the last three in Potosi), Chacaltaya in La Paz, Caluyo, Pacallo, and the Totoral. Gold in Cinti (San Juan river), Ancoraimes, Morochata, Surpo, Capasina, Amaya-Pampa, Chayanta, Yura (a river in Porco), Caiza, Linares, Pomabamba, Azero, Chuquiaguillo (La Paz district—in this placer mine was found a nugget of 22½ kilos), Santa Rosa (Chiquitos), Concepcion (Santa Cruz), Sorochi in Chayanta, Tipuani in Larecaja, Cajones, Yani, Chungamayo river, Suches (Caupolican), Araca (Loayza), Camaqueni, Ananea, Ayopaya, San Simon mountains, Guapore, Chiquiots, San Javier, Santa Rosa (province of Velasco), Paria, Choquecamata, Urulica (South Chichas), Chuquimia, Ipoco on the Oruro district, Capasisca, Atacama, in Susques, Tasonanco, Chuita, Choquehuata (Chayanta), Chichas, Ubina, Rosario, Olasos, Coroico, River Perry, Esmoraca, Sopachui, Presto, Chuquichuqui (Sucre), River San Juan (Chichas), San Jose del Abra, Huantajaguita, Siera Gorda, Collpa, Camol, Chitihue, Santa Maria, San Cristoval, Rosario, Catua, Guanaco, Obisidiana, Tipia (all in Atacama), High Guapore, Huarayos river, Vilaque in La Paz, La Paz river, Cavari, in Inquisivi, Cocapata, Cotacajes, Chumavi, Incasacani, and nearly all the rivers, especially in the provinces of Munecas, Larecaja, and Caupolican. Silver in Yamparaez, Tomina, Acero, Charasani (Munecas), Guarina, Omasuyos, Cavari, Carachapi, Mohoza, Ichoca, Carabuco, Inquisivi, Berenguela, Pacajes, Sicasica, Ayopaya and Mancaestancia, Chuyavi, Minascaca. Minasuta, Jalgular (department of Cochabamba), Colcha (Arque), Sayari (Tapacari), Quicoma, Mizque and Cliza. The whole departments of Oruro and Potosi, the same as in the department of Atacama. Platinum in San Javier and San Ignacio (Santa Cruz), in Illampu mountain. Lead in Cinti, San Cristoval (Oruro), Chichas, Andacava, Sombrio, around Potosi, Carabuco, and Escoma (Omasuyos), Araca, Tres Cruces, Inquisivi and Yaco. Petroleum in Tumupasa, Caupolican, Tacuru (Santa Cruz), around the city of Santa Cruz, Buena Vista, Serranias de Espejos, in the province of Cordillera. Precious stones on the north of San Ignacio (Santa Cruz), in the mountains between Callapa and Ulloma of the province of Pacajes, Caquingora, Lipez, Atacama, Santa Corazon, Candelaria (department of Oruro), and Salinas de Garci-Mendoza.

MADAGASCAR.

The French Government has prohibited prospecting for gold in Madagascar. This affects many miners from the Rand, South Africa, who have located claims and got money to exploit the gold deposits. The Madagascar minerals known in commercially exploitable quantities are gold, iron, copper, coal and tin. The gold is obtained mostly from placers.

MEXICO.

J. I. Limantour, Minister of Finance, has made plain the new regulation covering the collection of taxes on mining claims in the following circular to the director of the stamp revenue: "With a view to the application of the amendments made by Art. 10 of the decree of March 25 last, in the law governing the mining tax, the President of the republic has been pleased to direct that, when the claims (pertenencias) of one and the same company are embraced under a single title deed, the tax shall be collected from the outset at the rate of 6 pesos for the first twenty-five claims and 3 pesos for each claim in excess; and that, when the property of a company is constituted by various mines, each covered by a separate title deed, the tax shall be collected at the rate of 6 pesos per claim for each group if the area of said group does not exceed twenty-five claims, or, in the form above mentioned, if it does exceed said number, but always separately for each group; which, however, does not prevent the interested parties from having recourse to this department and demonstrating to it, with a view to the assessment of the tax, that the claims (pertenencias) covered by different title deeds are, nevertheless, contiguous to one another, and in such cases the resolutions that may be reached will in due course be communicated to you."

Jalisco.

The Mascota M. Co., operating north of Mascota, has completed a smelter of 100 tons. H. S. Church, manager of the company, has been operating an experimental plant for several months and has extracted 35% of zinc from the company's ore.

Sinaloa.

C. Butterfield and associates of Los Angeles, Cal., have acquired the Oro Fino properties, in the Sierra Madre, 30 miles beyond Rosario, and are putting in a 10-stamp mill.

Sonora.

The report of W. S. Cranz, president of the Zambona Dev. Co., which has taken over the Minas Nuevas, near Alamos, says that, since taking over the Zambona, Superintendent A. Yaeger has taken out the water and commenced placing guides in the main shaft, which is 530 feet deep. A new head-frame was put up, a tramway built, arrangements for handling the ore completed and the mine is now in condition for regular work. The mill is expected to be ready Aug. 1. An electric plant, capable of running a high-pressure main pump and electric hoist for underground work, is being put in. A new steam hoist for the main working shaft is expected to be in operation by July 8. In the mill most of the old machinery has been torn out, but it has been thought advisable to put the twenty stamps in repair. Besides the stamps, the mill will have sizing screens, a slime separator and six concentrators. It will be equipped with a water-saving system, as the water is from the surface thus far and is variable. It is the intention to double the capacity of the mill as soon as everything is in working condition, by crushing much coarser in the batteries and finishing the fine crushing with grinders.

Personal.

R. C. SHAW has returned from Costa Rica to New York City.

J. F. BRANDES of Denver, Colo., is on a professional trip to Utah.

H. BLAKE is superintendent Gold Bug mine, near Sumpter, Or.

W. A. KIDNEY is manager Basin Reduction Co., Basin, Mont.

OSCAR WHITE is superintendent Slocan Star mine, at Sandon, B. C.

S. P. DONNER is manager Ben Hur G. M. Co., near Republic, Wash.

W. R. WAPPLES has charge Pioneer mill at Sandy, Salt Lake county, Utah.

W. W. MILLS has been appointed State Geologist of Michigan, to succeed A. C. Lane.

H. F. BEST is manager Treasure Hill mine, Stockton Hill district, near Kingman, Ariz.

B. CLAPHAM, superintendent Fordice M. Co., has left Custer, S. D., for Columbia, Iowa.

AL. ROBERTS has been appointed superintendent January mine at Goldfield, Nev.

A. J. HOSKIN has been appointed assistant professor mining in Colorado School of Mines.

T. R. GARNIER of Los Angeles, Cal., has been at the St. Louis mine, near Kingman, Ariz.

E. W. BRADEN, manager East Helena, Mont., and Monte Cristo smelters, is in San Francisco, Cal.

E. P. FARNHAM of Deadwood, S. D., has been elected superintendent Chicago & Black Hills G. M. Co.

W. R. INGALLS assumes editorial charge of the Engineering and Mining Journal of New York to-day.

C. L. TUTT, president Takilma and Waldo mining companies, has been visiting the smelter at Takilma, Or.

N. HAAS of Spokane, Wash., has accepted the position of mining engineer for the Snowshoe mine at Libby, Mont.

A. W. MCCUNE has returned to Salt Lake City, Utah, from the mines of the Cerro de Pasco Copper Co. in Peru.

M. P. KIRK of El Paso, Texas, has succeeded W. L. Study as superintendent Big Bend M. Co. at Big Bend, Texas.

NORMAN CARMICHAEL, manager Highland mine, Ainsworth, B. C., has returned from a business trip to England.

C. P. AMES, formerly of Deadwood, S. D., has charge of the cyanide department of the Mainstay mill at Keystone, S. D.

A. D. WHEELER, formerly superintendent Hunter V mine, near Ymir, is operating the Krao mine, Ainsworth, B. C.

G. S. BINCKLEY has returned to San Francisco, Cal., from a professional trip to Santa Barbara and Los Angeles, Cal.

J. D. SPARGO, formerly superintendent Gold Road mine, will take charge of the West Gold Road M. Co., near Acme, Ariz.

T. A. RICKARD has resigned as editor of the Engineering and Mining Journal, the resignation going into effect on June 30.

A. H. ELFTMAN, who is now at Roosevelt, Idaho, will investigate properties in Nevada and may be addressed at Tonopah, Nev.

G. H. GRANT has taken charge of development work on the June group, Quatsino Sound, west coast Vancouver Island, B. C.

F. L. HARRINGTON of Bisbee, Ariz., vice-president and general manager Saginaw D. Co., has charge of work on the property.

W. Y. WILLIAMS, late superintendent Granby mines at Phœnix, B. C., has returned from a visit to Europe to the Similkameen district.

HUDSON H. NICHOLSON, general manager Standard Consol mine, is in Denver, Colo., on his way to San Juan, Colo., on professional business.

N. MCL. CURRAN, manager North Star mine, Kimberley, East Kootenay, B. C., has returned to the mine from a trip to Montreal, Quebec.

H. M. STEVENSON, manager Highlander mine at Ainsworth, B. C., has returned from a six months' visit to Mexico and the Eastern States.

H. A. PERKINS has resigned as manager New Era M. Co., Searchlight, Nev., and President W. R. Grosewich has been appointed his successor.

W. J. MORPHY, manager American Gold Fields Co., is in San Francisco, Cal., buying machinery for the Granite Hill mine, near Grants Pass, Or.

THOS. BAKEWELL, formerly with the Fearnot M. Co., Victorville, Cal., is now foreman Marfa & Mariposa M. Co., producing quicksilver at Terlingua, Texas.

T. C. LENTZ of Columbus, Ohio, president Ohio-Beaver Creek M. & M. Co., has been visiting the property in western Lawrence county, South Dakota.

H. C. HOOVER of the London firm of Bewick, Moreing & Co. left San Francisco, Cal., on the 29th ult. for Australia, where they have large mining interests.

JAMES W. NEILL, mining and metallurgical engineer who has served the United Copper Co. and F. A. Heinze in Butte as chief engineer for the past eighteen months, has severed his connection with these parties and has resumed his consulting engineering practice with headquarters at the Palace Hotel, San Francisco, Cal., and Dooly block, Salt Lake City, Utah.

DR. ROBT. H. RICHARDS of the Massachusetts Institute of Technology, and author of a comprehensive work on "Ore Dressing," is in San Francisco, Cal., accompanied by F. W. Horton, E. M. They are on their way to Portland, Or., where they will take charge of the work of investigating the platinum-bearing black sands of the United States, under the direction of Dr. David T. Day of the United States Geological Survey.

Books Received.

"Index to the Hydrographic Progress Reports of the U. S. Geological Survey, 1888 to 1903," by J. C. Hoyt and B. D. Wood.

Folio 123 of the United States Geological Survey, "Elder's Ridge, Pennsylvania," gives topographic and geological maps and description of the coal fields of western Pennsylvania.

As extracts from "Mineral Resources of the United States for 1904," the United States Geological Survey publishes "The Production of Mica in 1904," and "The Production of Arsenic in 1904."

Bulletin No. 262, "Contributions to Mineralogy from the U. S. Geological Survey," includes discussions on carnotite and associated vandiferous minerals in western Colorado; additions to the alunite-jarosite group; minerals from Clifton-Morenci district, Ariz.; emmonsite and tedradymite (tellurium minerals) from Colorado; lawsonite, yttrialite, pseudo-serpentine from Stevens county, Wash.; californite and dumortierite.

Obituary.

F. A. HUNT, a pioneer mining man of Denver, died in Denver, Colo., June 22, aged 70 years.

CHARLES CHRISTY, formerly superintendent of a large mining syndicate near Port Arthur, Manchuria, died June 26 at the Stockton, Cal., Insane Asylum.

ALFRED BENNETTS, lessee of the Landers mill at Silver City, Nev., and one of the prominent mine owners of the Comstock, committed suicide June 28. He was 53 years of age.

Commercial Paragraphs.

THE Crane Co., Chicago, Ill., have moved their general offices from 10 North Jefferson street to 519 South Canal street.

GEO. W. MYERS has returned to San Francisco, Cal., from a trip to the northern Pacific coast States and Alaska and reports large sales of chrome steel shoes, dies, etc. He leaves San Francisco in a few weeks for an extended trip to Australia and New Zealand.

THE Cyclone Drilling Machine Co. of Orrville, Ohio, report a phenomenal sale of prospecting drills, blast hole drills and "Economy" blast hole loaders. Since introducing the "Economy" blast hole loaders among the railroad contractors the sale of them has increased rapidly, many contractors having placed orders to supply their different camps.

THE Bethlehem Steel Co. is at work on three crank shafts which will weigh 86,600 pounds each when finished. They are turned out of solid steel ingots 25x4x4 feet, and are intended for three gas engines which are to drive 4000 kilowatt Crocker-Wheeler alternators, said to be the largest gas engine driven generators ever built, and ordered by the California Gas & Electric Corporation.

THE National Wood Pipe Co. of Los Angeles, Cal., and San Francisco, Cal., have made a shipment to the Detroit Copper Mining Co. of Morenci, Ariz., of 14-inch machine-banded redwood water pipe made for a head of 250 feet, or 108 pounds pressure per square inch, to be used by them for conveying water for their concentrators. They claim that this pipe is particularly adapted for water and soils heavily charged with acids, minerals or alkali. The staves for this pipe are made from 1½x4-inch clear, seasoned redwood stock. The Cananea Consolidated Copper Co. are using 8-inch, 10-inch, 12-inch and 16-inch machine-banded redwood water pipe for conveying water to the concentrators.

THE Chicago Pneumatic Tool Co. has brought suit in the U. S. Circuit Court for the southern district of New York against the Aurora Automatic Machinery Co. and the Scully Steel & Iron Co. for alleged infringement of the Chicago company's Kimman patent No. 630,357 of August 8, 1899. The bill of complaint prays for an injunction and an accounting for profits and damages against both companies. The Aurora Automatic Machinery Co. is the manufacturer of the "Thor" pneumatic tools and is represented by the Scully Steel & Iron Co. as selling agents in New York City. The suit is brought to enjoin the Aurora Co. from continuing to manufacture and sell the alleged infringing tools and the Scully Steel & Iron Co. from continuing to sell and offer for sale such tools. The application for an injunction to enjoin both companies will be heard at an early date. The Chicago company claims that the so-called "Thor" pneumatic tools infringe not only the referred to Kimman patent, but some of its other patents, and that the present suit will be followed in quick succession by other suits of a like character.

Trade Treatises.

"Mine Cages, Skips and Ore Cars" forms the subject of the latest trade treatise from the Wellman-Seaver-Morgan Co., Cleveland, Ohio, beautifully illustrated and finely descriptive of such mine appliances.

The S. H. Supply Co., Eighteenth and Lawrence street, Denver, Colo., have issued a neat catalogue describing Wild's shaking screen for ore sizing. It is designed to screen wet or dry, or fine or coarse.

Bulletin No. 58 from the Crocker-Wheeler Co., Ampere, N. J., is entitled "An Electrified Railway Shop Described by Its Mechanical Engineer," and shows how electric devices and appliances were successfully used in economically supplanting the former system in a large machine shop. The manifest economic value of the treatise is supplemented by the practical manner in which the various changes were effected.

"The Pelton Water Wheel" is the subject of an elaborate trade treatise issued in sumptuous style by the Pelton Water Wheel Co., 125 Main street, San Francisco, Cal., and 143 Liberty street, New York City. It is the tenth 1905 edition of a monograph that sets forth the variations of construction and application of the Pelton system of power, and in its arrangement and general plan is worthy of the establishment whose power producers are therein so finely illustrated and described. The book is standard size and deserves a place in the working library of a mining or hydraulic engineer.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JUNE 20, 1905.

792,747.—LEAF BINDER—Anderson, Weinss & Miller, Spokane, Wash.
792,875.—BLOCK SIGNALS—C. P. Bass, Portland, Or.
792,756.—SIGNS—H. Christensen, Seattle, Wash.
792,815.—SHOE POLISHER—S. M. Cohn, Portland, Or.
792,966.—DOOR FASTENER—Coleman & Gregory, Index, Wash.
792,587.—RAIL TIE—T. A. & J. V. Enloe, Pinole, Cal.
792,699.—EXCAVATOR—W. H. Fulcher, Oakland, Cal.
792,770.—VEHICLE SHAFT—F. C. Goetteri, Los Angeles, Cal.
792,987.—AIR COMPRESSOR—G. J. Henry, Jr., S. F.
792,991.—BOTTLE—F. Jost, S. F.
792,779.—GRAMAPHONE—G. Konigstein, S. F.
792,717.—GARMENT CLASP—Mensor & Greenblatt, Seattle, Wash.
792,718.—HEADLIGHT—O. E. Mitchell, Los Angeles, Cal.
792,840.—LOOSE LEAF BINDER—M. C. Neuner, Los Angeles, Cal.
793,020.—SWAGE—Newell & Staley, Buckeye, Wash.
792,610.—METAL COATING TANK—G. Porter, S. F.
792,923.—MONEY BOX—W. N. Porter, Lents, Or.
792,792.—ELECTRIC IRON—E. H. Richardson, Ontario, Cal.
792,821.—CAN—A. H. & T. A. Schlueter, Oakland, Cal.
792,734.—ELECTRIC SWITCH—H. A. Schultz, Berkeley, Cal.
792,949.—PUNCH—L. Van Dorin, San Bernardino, Cal.
792,687.—PROPULSION—K. O. Woll, Tacoma, Wash.
792,648.—DRILL SHARPENER—J. H. Word, Soulsbyville, Cal.

Latest Market Reports.

SAN FRANCISCO, June 30, 1905.

METALS.

SILVER.—Per oz., Troy: London, 27d (standard ounce, 925 fine); New York, bar silver, 58⅝c, refined (1000 fine); San Francisco, 58⅜c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.00; Lake, 1 to 3 casks, $15.00@15.25; Electrolytic, 1 to 3 casks, $15.25; Casting, 1 to 3 casks, $14.50@14.75. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £66 2s 6d spot per ton.

An Eastern authority says in the Boston Financial News: "The statistical position of the metal is so strong that I do not expect the level of prices to be lowered beneath the 15-cent mark for at least a year. The general feeling is that an early peace between Russia and Japan might have effects that have not been calculated. At the present time the life of the market is the demand from European sources, and this demand has been largely stimulated by what is called Chinese buying. Whether this nomenclature is correct or not is a matter of question to those who know the circumstances. It has been known that a great deal of copper from Japanese sources has been consumed in China, and that this supply has largely been cut off by the war. But the Japanese themselves have consumed great masses of the metal for manufacture into brass, which is largely used in the manufacture of cartridges and other war paraphernalia. It does not escape notice that copper so used might have been considered contraband of war, and as the lines which have their terminals in Hongkong all pass through at least two Japanese ports, it is a matter entirely of conjecture as to how much of the copper bought for the Chinese mint has really arrived there and how much has found its way to Japanese sources. This matter is important only in considering what effect the end of the war will have on the continuance of the demand. The logical conclusion to be reached is that with the ending of hostilities the Japanese mines will again begin production on the same scale that obtained before the war started. The insistent demand for the metal will abate and the demand can be filled leisurely. If that should prove to be the case, there would undoubtedly be a lessening of the demand for copper that might well affect the market adversely."

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.12½; San Francisco, $3.70, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £13 6s 3d ℔ long ton.

SPELTER.—New York, $5.30; St. Louis, $5.70; London, £24 ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

QUICKSILVER.—New York, $39.00@$40.00, large lots; London, £7 7s 6d; San Francisco, local, $38.00@38.00 ℔ flask of 75 lbs.; Denver, $45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.75c; San Francisco, Plumbers', 100-lb. lots, 17.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.60; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $23.00@$23.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lbs. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ℔ set; 14 oz., 40s., 9¾c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¾c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¼@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¾@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 62c; cs., 67c; raw, bbl., 60c; cs., 65c; Lucol oil, boiled, bbl., 54c; cs., 59c; raw-bbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

MOLYBDENUM.—Best, $2.75 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

URANIUM.—Oxide, ℔ lb., $3.50.

MERCURY.—Bichloride, ℔ lb., 77c.

TUNGSTEN.—Best, ℔ lb., $1.25.

PHOSPHORUS.—American, ℔ lb., 70c.

SODIUM.—Metal, ℔ lb., 50c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MAGNESIUM.—Pure, N. Y., $1.60.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

MULTIPLE-VIEW CAMERA.—No. 792,245. June 13, 1905. James W. Anderson, Santa Cruz, Cal. This invention relates to improvements in photographic apparatus, and pertains especially to a multiple or consecutive view camera or camera attachment employing a sensitive glass plate, cut film, or any flat sensitized surface upon which may be photographed in more or less rapid succession objects in their various natural positions or movements. The main object of the invention is to provide a camera or an attachment for a camera particularly adapted for gallery use which will enable the operator to take a series of pictures of moving or stationary objects in most rapid succession on one plate or which will allow each photo separately to be given a prolonged exposure, as by removing the cap each time in the manner of ordinary multiple cameras, or which will permit the whole plate to be exposed at one exposure, as for ordinary portrait work. The invention comprises mechanism for imparting an intermittent horizontal reciprocating movement to a plate across a light aperture and a movement of the plate transverse to its line of reciprocations whereby the plate momentarily is stopped during each exposure and whereby the whole sensitive surface may be taken up with one or more rows of distinct individual pictures.

CONTAINING AND POURING CAN.—No. 792,621. June 20, 1905. Adolph H Schlueter and Theodore A. Schlueter, Oakland, Cal. The object of this invention is to permit the withdrawal of liquids from larger to smaller receptacles without overflow and waste and to provide an apparatus for this purpose which can be effectively used without a faucet or separate filling nozzle. The device consists of an improved containing can having an air tube contained wholly within it, having one end fixed in the head of the can, said tube extending at an angle toward the side of the can and terminating short of said side, a filling nozzle connecting directly with the opposite or outer end of said tube, and a siphon-shaped pouring spout fixed in the head of the can at one side of the center thereof.

EXCAVATING APPARATUS.—No. 792,699. June 20, 1905. William H. Fulcher, Oakland, Cal. This invention is designed for making excavations of any sort, especially for digging ditches or canals, removing the earth and delivering it either to form embankments or to discharge it at a distance from the digging apparatus. It is also susceptible of use in removing earth which is piled above the surface, leveling it or changing its grade, and for various similar operations. The device comprises a frame having turnable bearings and guiding wheels, cables connecting with said wheeled frames winding drums by which said cables are moved to turn the wheels of a motor carried upon the main frame, reversible clutches, mechanism comprising chain and chain pulleys whereby motion is transmitted to the wheel-steering apparatus.

AUTOMATIC ELECTRIC SWITCH.—No 792,734. June 20, 1905. Herman A. Shultz, Berkeley, Cal. This invention relates to an apparatus by which pumps and other machinery may be automatically set in motion or their operation discontinued through the medium of an electric current. The object of the invention is to provide a simple, practical form of electrical circuit-closing mechanism which is applicable for use particularly in the pumping of water, such as in cellars, basements, mines and other places where flooding or overflow is liable to occur and where the rise and fall of the water will start or stop a suitable pump or equivalent apparatus for reducing the amount. The device consists of the combination with an electric switch, of a float, of a fulcrumed lever, connections between the float and the lever, connections between the lever and a movable member of the switch, and a wedge-shaped yieldable member against which one end of the lever is traversable.

GRAMOPHONE ATTACHMENTS.—No 792,779. June 20, 1905. Gabor Konigstein, San Francisco, Cal. This invention relates to an attachment which is designed for use in conjunction with the movable arms of gramophones or talking machines; and it is especially designed to protect the diaphragm and its attachments from injury. The device comprises a readily attachable and removable cap-shaped member adapted to fit the sound box of a gramophone, said member serving to protect the stylus-support of the box and being made perforated to permit the free passage of sound-waves.

ASSESSMENT NOTICE.

ALTA SIERRA GOLD MINING COMPANY.—Location of principal place of business, Room 620, Kohl Building, 406 Montgomery street, San Francisco, California; location of works, Sierra County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 22nd day of June, 1905, an assessment (No. 2) of thirty (30) cents per share was levied on all the issued capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, Room 620, Kohl Building, 406 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Saturday, the 19th day of August, 1905, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 18th day of September, 1905, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

SAM. W. CHEYNEY, Secretary.

Office—Room 620, Kohl Building, 406 Montgomery street, San Francisco, California.

DRY PLACER MACHINES

THE PNEUMATIC PROSPECTOR.

Size 6x11x14 in. Weight only 10 lbs.

PACKED FOR MOVING.

NO WATER NEEDED.

Gives a clean prospect from Placer ground or free-milling ore by compressed air. The operation is purely mechanical. No chemicals, no quicksilver; no black sand remains with the gold. Will do work equal to careful panning.

THE PNEUMATIC SEPARATOR.

Weight 160 lbs.

Has a capacity of 20 to 30 cu. yds. of gravel per day. Will save fine and coarse gold and nuggets of any size, comparatively free from black sand. Will do better work under favorable circumstances than a sluice box. Indispensable for dry countries

SITUATIONS WANTED.

☞ *The cost of advertising in this column is 10 cents per line of seven words per insertion. Answers forwarded to any address without extra charge.*

ASSAYER, TECHNICAL GRADUATE, WANTS position in mining camp. Experienced chemist. References given. Address J. A. W. Luck, Jersey P. O., Contra Costa Co., Cal.

EXPERT MILL MAN WANTS POSITION AS mill superintendent and assayer. Has done cyaniding and can keep accounts. Address "Milling," this office.

EXPERIENCED HYDRAULIC MINE MANager, formerly in charge Cherokee, La Grange, North Bloomfield and other large California hydraulic mines, wants engagement. Exceptional references as to standing, character and efficiency. Address J. B. D., Mining and Scientific Press office.

MILLWRIGHT AND MACHINIST WANTS position with mining company; 10 years experience; good draftsman and designer; thorough knowledge of mining work. "Mechanic," this office.

MINE SUPERINTENDENT DESIRES POSItion. Practical miner, mill man and cyanide chemist. Address "Super," this office.

MINING ENGINEER AND SUPERINTENDent, with twelve years' continual experience. Superintendent for five years. Excellent references. J. Lancaster, 622A Placer St., Butte, Mont.

POSITION BY THOROUGHLY PRACTICAL mine and mill superintendent of over 30 years' experience. Profitable handling of low-grade ores a specialty. Climate no object. Can give reference from first-class mining companies. Address "Utility," care of Mining and Scientific Press.

TECHNICAL GRADUATE WISHES POSITION. Experienced in assaying mine, mill and cyanide plant samples and products, and in operating cyanide plant. Not particular as to location. References, last employer. Address M.C.D. this office.

THE ENGINEERING AGENCY, 128 MONADnock Block, Chicago, furnishes free to reliable employers information leading to employment of Mining Engineers, Draftsmen, Mine or Mill Superintendents, Assayers, Chemists, Cyanide Men, Electricians, etc. In successful operation eleven years. Let us know your need and competent, high-grade men whose complete professional and personal records have been thoroughly investigated will be referred to you at once.

WANTED — SITUATION AS MANAGER OR Superintendent of gold, silver or lead property; 20 years' experience in managing properties, building mills, and ore concentration. Good assayer, surveyor, etc. Best of reference. Address C. J. A., care of this office.

WANTED—POSITION AS SUPT., CHEMIST OR Assayer—mine, cyanide, chlorination plant or smelter. Am technical, and plenty of experience. Address H. B. S., 346 Bradbury Bldg., Los Angeles.

WANTED POSITION AS ASSAYER. UNDERstands milling and cyaniding. Address Box 28, care of this office.

HELP WANTED.

WANTED FOR MEXICO—AN EXPERIENCED Mine Manager, also a competent Mill Superintendent used to cyanide treatment. Both must speak Spanish, and have had an extensive experience. Apply, with copies of testimonials and stating terms and past experience, to Box No. G. 3036, Haddon's Advertising Agency, Salisbury Square, Fleet St., London, England.

THIS IS A CLEARING HOUSE FOR ENGIneering or technically trained college men and positions. No charges to employers. Supplying teachers a specialty. Circulars on request. The Science Agency, Durham, New Hampshire.

For use in and about mines.

A weekly talk on the merits of the products of

The Paraffine Paint Company

THE USE OF MALTHOID ROOFING ON MINE BUILDINGS.

Malthoid Roofing is used on mine buildings because experience has taught mining contractors and builders that it wears better than any other roofing and costs less to keep in good repair.

There is a reason for this and a very simple one, too.

Malthoid Roofing is made of the highest grade of wool felt, thoroughly saturated with a non-drying, gummy compound that will always remain soft and pliable whether the weather be cold or very hot. This is coated with a non-oxidizing, tough and elastic weather-proof coating.

The combination of these ingredients (most of which are produced in California) forms a water-proof fire-resisting roofing that is exceptionally strong, very durable, and easy to lay.

A Malthoid Roofing will resist fire and burning sparks falling upon it will not ignite it.

It does not curl, melt, run nor crack from hot weather. Neither does it contract, buckle or creep from cold weather.

It is specially useful on mine buildings near smelters where gases and fumes and exhaust from steam pipes forming an acid fall upon the roof. Such conditions do not injuriously affect Malthoid in the least.

It can be used for all sorts of buildings, laid in a few hours—full instructions for laying, together with cement, nails and caps, contained in each roll.

Where transportation and freight rates are difficult and high, Malthoid is a splendid substitute for lumber.

Malthoid is a non-conductor of heat and cold, and as such renders houses made of it cooler in summer and warmer in winter.

We have several folders and circulars issued about Malthoid which we will be glad to send to any one interested. In fact, we are issuing folders and circulars constantly showing new buildings recently covered with this popular roofing.

The Vancouver Cement Company, covered with 49,000 square feet of roofing.

THE VALUE OF P & B PAINT ABOUT MINES.

The Omaha & Grant Smelting and Refining Company of Omaha, Neb., say: "We are using your P & B Paint in our Blue Stone Works, where it is subjected to the action of sulphuric acid, and find it the best article we have ever used for that purpose."

The Bridgeport Copper Company, of Bridgeport, Connecticut, say that they have used considerable quantities of No. 1 P & B Paint and have found it better than anything else for resisting a dilute solution of sulphuric acid.

P & B Paint is particularly useful about mines for painting boilers and smokestacks, brick, cement and stone work, roofs, pipes, all sorts of iron work, above and below ground. P & B Paint will stand great extremes of heat and cold, and will neither crack, run nor scale. Its color is a bright black, and dries quickly, absolutely odorless and tasteless. It comes in cans ready to apply, requires no heating, mixing or stirring.

A gallon of P & B Paint covers from 150 to 250 square feet of surface, according to the grade you use. We have some interesting literature on the subject of preservative paints we will be pleased to send to any one interested enough to send for it.

We also manufacture P & B Ready Roofing, P & B Building Paper, P & B Insulating Tape, and Pabco Damp-proof Compound, our latest product, used for coating brick walls before plastering. It takes the place of fur and lath, and prevents the moisture in the bricks entering the plaster.

Booklets and full instructions for using all of our products sent free on request.

The Paraffine Paint Company,

Main Office, 24 Second St., San Francisco, Cal.

Factories, Paraffin, Cal.

Branches: Los Angeles, Denver, Portland, Seattle, Spokane, New Orleans; Sydney, N. S. W.; Shanghai, China; and Yokohama, Japan.

A SCIENTIFIC TEST

The late Prof. Thurston says in his treatise, which has been accepted as an authority on Friction:

"Friction may be said to be in proportion to the heat generated."

Tinius Olsen, the noted M.E. and builder of Testing Machinery, upon testing samples of the best known oils and greases on the market, reports:

"The bearing tested, running under the same conditions and the same length of time, grew hotter with each other lubricant than with KEYSTONE GREASE."

Is it necessary to draw a conclusion?

We will send a sample of KEYSTONE GREASE and a brass grease cup to any Engineer giving business address, and advising us of the H. P. of his engine and size of tap in which cup will be used.

GUARANTEE:

1 lb. of KEYSTONE GREASE=4 to 6 gals. of OIL.

1 lb. of KEYSTONE GREASE=3 to 4 lbs. any other grease.

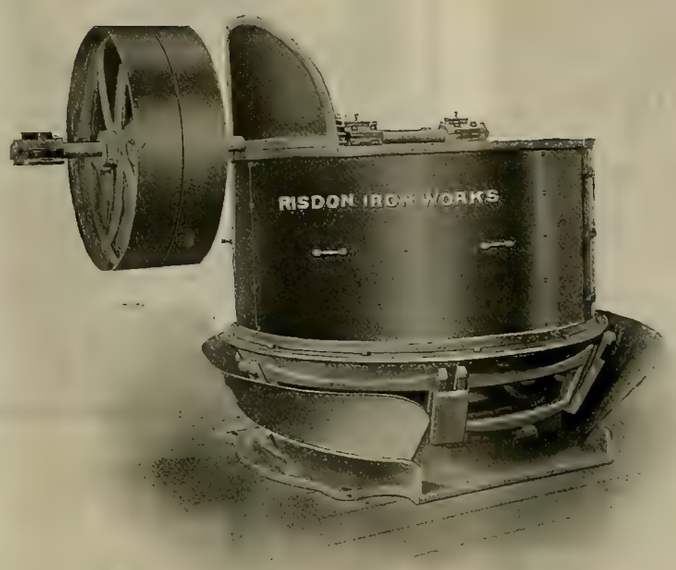
KEYSTONE GREASE is made and sold only by us; any dealer offering KEYSTONE GREASE is offering a substitute and will be prosecuted for the imposition.

LUBRICANT

Keystone Lubricating Co.

PHILADELPHIA, PA., U. S. A.

Bryan Roller Mills



BRYAN ROLLER MILLS are to-day successfully operating in every important mining district in the world. They are the most simple, durable and efficient mills on the market—more economical than ore-reducing machinery to buy, transport and erect. They require less power per ton of ore crushed than any other mill. They make little or no slime and produce a more granulated product than stamp mills.

The mill shown in the illustration is one of eight new mills recently installed in the regrinding department of the Cananea Consolidated Mining Company.

Send for catalogue number eight. Prices quoted upon application.

RISDON IRON WORKS, 270 STEUART STREET, SAN FRANCISCO, CALIFORNIA.

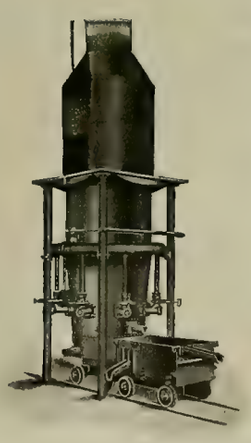
Western Sales Agents:
HENDRIE & BOLTHOFF, Denver, Colo.

Complete Smelter for Sale.
A BARGAIN.



This plant is complete in every detail and contains the following principal items of machinery:

A 36-INCH ROUND WATER-JACKETED COPPER MATTING FURNACE WITH FOREHEARTH (exactly as shown in illustration), NO. 4½ POSITIVE PRESSURE BLOWER, SLAG POTS, MATTE POTS, ENGINES, BOILER, HEATER, CHARGING SCALES, AND ALL PULLEYS, SHAFTING, BELTING, ETC.

This furnace is brand new, having been purchased by a company who changed their plan of treatment before the furnace was shipped. It has just come from the factory and is a strictly modern machine in every particular. The balance of the machinery has been in use a short time, but is in thoroughly first-class condition in every respect.

We will sell this as a whole or in any part. Write us your requirements and we will furnish you complete specifications and prices.

The S. H. Supply Co.
1803 Lawrence St., DENVER, COLO.

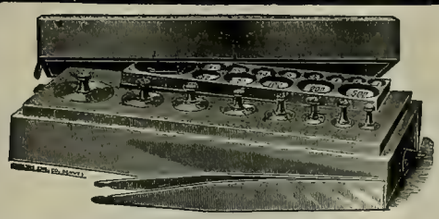
INTERNATIONAL STANDARD



Metric Weights

We guarantee our weights to be accurate subdivisions of the INTERNATIONAL STANDARD KILOGRAM, as furnished us by the BUREAU OF STANDARDS at Washington, and are prepared to supply sets of weights for button weighing (1 platinum gram to 1 mg.) with guaranteed error limits of + or — .01 mg. and + or — .005 mg., something heretofore never attained.
These weights, when used with our Assay Ton Weights (based upon the same standard) for pulp, guarantee greatly increased accuracy in assaying.

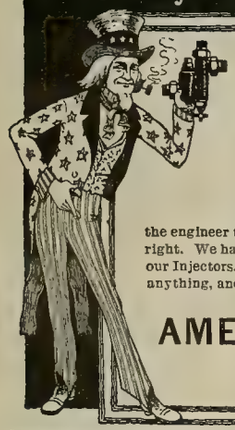
U.S. Automatic Injectors



OUR SAY SO

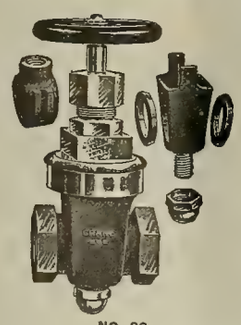
doesn't make our U. S. Injectors the best. Ask any engineer who has used them; he knows. Once a user of the

U. S. Injector

the engineer takes no chances, and he sticks to the Injector that he knows is right. We have converted over 200,000 engineers in twenty years to the use of our Injectors. Send for our little "Engineers' Red Book." It won't cost you anything, and there is a world of useful information in it for the engineer.

AMERICAN INJECTOR CO.,
DETROIT, MICH.

CRANE



RENEWABLE SEAT AND DISC

VALVES

NO. 88

SUITABLE FOR A WORKING PRESSURE OF 250 LBS.

The renewable parts are made of hard and superior composition, far better than the usual composition put into Valves, and we do not hesitate to say they will last many times longer than those in the ordinary Valve.

They are especially suitable for any hard work where extreme pressure is used and where the wear and tear on the Valve is most severe.

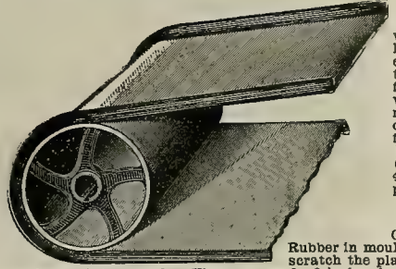
SPADONE'S CONCENTRATOR BELTS.

PATENTED.



This illustration shows the edge flanging outwardly as it passes over the pulley. This relieves the strain from the top and bottom of the edge by directing the strain automatically to the inside face surface of the edges. Heretofore all belts have been so constructed that when they pass over the pulleys or rolls, a direct strain comes upon the top or at the base of of the edges, causing the edges to break away from the body of the belts in a very short time. *We avoid this Mechanical Defect by our Spadone Curved Edge.* Belts made to fit any machine—4, 5 and 6 feet wide. Prices and samples on application.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleaners are made of Pure Rubber in moulds, thus insuring a plate cleaner which will not scratch the plates and a perfect edge which will clean the Amalgam plates evenly. They are made 6 inches long, 3 inches wide and ¼ inch thick, making a convenient size to handle. Price by mail to any address, each 75 cents. Correspondence solicited.

FIREPROOF CEILINGS.

Corrugated Tanks
For Cyanide Purposes.

For cyanide purposes the corrugated tanks are much superior to plain tanks, for two reasons:

1. The corrugations act as baffles and throw the solution into the sand, thereby assisting the cyanide in percolating the ores instead of running up and down the sides, as is the case with plain tanks.

2. A corrugated tank has in it 10% more material and being arched three ways makes it 6¾ times stronger than ordinary tanks.

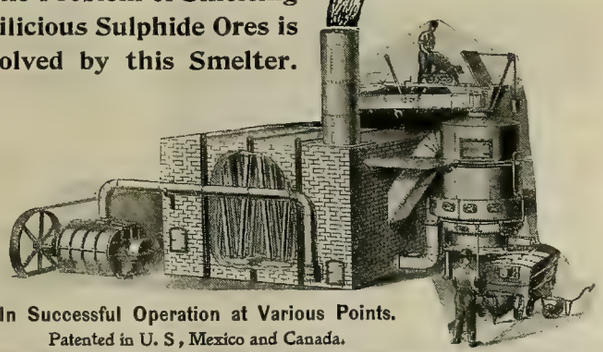
A SUCCESSFUL SULPHIDE SMELTER

The Problem of Smelting Silicious Sulphide Ores is Solved by this Smelter.



In Successful Operation at Various Points.

Patented in U. S, Mexico and Canada.

The MacDonald Smelter

SAVES THE PRECIOUS METAL VALUE AT LOW COST.

Especially Designed for Silicious Sulphide Ores Carrying Gold, Silver and Copper Values. Very Successful.

This Smelter is no experiment, having been in continuous and successful operation for nearly three years in Mexico on complex and refractory sulphide ore of low value. First a 40-ton plant was erected at El Oro, then two 60-ton Smelters, and in September, 1904, a 150-ton plant was put in operation and another 150-ton Smelter is being added. Metallurgists who have visited and inspected the Smelters in operation in Mexico report that they are doing more than we claim for them. One of our 60-ton outfits is now erected near Valardena, Mexico, by a Chicago company. A second Smelter of larger size is also contracted for.

DESCRIPTIVE MATTER COVERING EVERY POINT ON APPLICATION.

The Honerine Mill, Utah.

One mile from Stockton, in Tooele county, Utah, and on the east side of Tooele valley, is the Honerine mill, which is treating the ore from the Honerine mine and also the tailings from the dump of the old Honerine mill. The accompanying illustration shows the Honerine mill, with the track running into the mill from the drainage and transportation tunnel, also the railroad track underneath where the cars are filled with concentrates from the side of the building by means of iron chutes. The photo shows the machine shop and end of mill. The mill is fully equipped with modern devices for the treatment of the ore. The tailings from the old mill dump are being hauled about 1300 feet and run down to a chute in the tunnel through an air shaft and from there hauled in trains by mules to the mill. The ore is handled by conveyor, which delivers it from bins to the mill, where it is crushed and elevated to a trommel filled with ½-inch mesh screen. The oversize goes to rolls and is crushed dry. The fine ore is elevated to the top of the mill where it passes through an automatic sampler, the mill throughout operating automatically, by gravity and elevating devices. In the mill are three Huntington mills, one Chile mill, jigs and sizing devices, beside the Sherman system of hydraulic classification. From the Sherman classifiers the pulp goes to Wilfley tables and slimers, of which there is a total of twenty-six machines.

The Honerine Mill, Near Stockton, Utah.

Passing of a Lake Superior Copper Mine.

The Phœnix mine, comprising over 2000 acres of land in the copper belt of the Keweenaw peninsula, Michigan, after an existence of sixteen years, has been closed indefinitely. The original Phœnix vein was vigorously explored from 1844 to 1886 and was an important producer in those days. The largest mass of copper ever discovered came from this mine. There are several veins on the property which are well equipped. A large mill was completed in 1903, but this has never run continuously to its full capacity. The ore carried about 1.5% copper. It is apparent that the small veins in this property have failed to yield sufficient ore to keep the mill in continuous operation. Some recent development is stated as having been disappointing. This withdraws one of the noted mines from the list of producers on the Lake, for a time at least, if not permanently, but its failure will scarcely be noticed.

Mining operations were commenced in the Lake Superior region about 1845, under permits issued by the War Department. Out of 1000 permits issued, 960 locations were taken. One of the first mines opened was the Cliff, in which was discovered the first mass of copper. The Cliff mine yielded a large amount of mass metal. Skilled men, known as copper cutters, were employed to cut these great masses into sizes that could be economically handled. Contrary to the common belief, masses are less profitable than when metal occurs in disseminated grains.

The Comstock Silver Mine, Near Park City, Utah.

Intake Side Pumping Plant, Bouldin Island, Cal. (See Page 28.)

Comstock Mine, Summit Co., Utah.

One of the important mines of Summit county, Utah, is the Comstock, situated in Thayner's canyon, in the Park City district, and is presumed to be on Silver King fissure system. The main shaft has three compartments, timbered with 12x12 inch, Oregon pine, and the property is also extensively developed by means of tunnels. The accompanying illustration shows the mine, dump and mill. The concentrating mill has a capacity of 120 tons per day. The Comstock vein can be drained by a tunnel at a depth of 2000 feet, connecting with the Alliance tunnel. The main offices of the company are in Salt Lake City, Utah.

Again the Broad Lode Case.

The "broad lode" question is again likely to receive considerable attention in the courts, in the suits recently instituted in the Cœur d'Alene district of Idaho, where at least two apex suits against the Bunker Hill & Sullivan Company will be tried. Whether the prior locator on a vein takes the entire lode within the end lines of the claim having a part of the lode only, the courts do not uniformly agree. In a few instances lodes are found to be of such great width as to extend outside of the side lines of the claim. Particularly is this the case in those sections where local laws have made narrow locations (less than 600 feet) the rule. In one instance a territorial court decided that the prior locator, having a portion of the apex, took the whole lode, even if it did extend beyond the side line. In another case where a claim was located along the strike of a broad vein, and a junior locator took up a claim on the portion of the lode beyond the senior locator's side line, but laid his end lines at an angle of about 45% to the side line, the court decided each had extralateral rights, but that the junior locator's rights did not begin until the vertical projection of the end lines on the dip had passed beyond conflict with the senior locator's rights—one following the dip of the vein in a direction normal to the strike of the vein, the other taking a segment at an angle conforming to the direction of the angling side lines. The complex conditions arising from the situation now again attracting so much attention in the Cœur d'Alenes teaches one lesson at least, and it will no doubt have a tendency to induce large companies in the future to secure all the ground possible, not only in their immediate vicinity, but far beyond, as a protection against lawsuits should the mines prove rich and extensive. There are few great mines in the Western United States where there has not been more or less litigation over adjoining properties before the legal rights of the several mine owners were determined by the courts. In a few instances a more wise policy has been pursued, and the contiguous property owners have agreed upon definite boundaries, and the rights of each have been well established, as in some of the copper camps of southeastern Arizona, but it is too late to expect to find anything of this sort in the mines about Wardner, Idaho, when large sums of money are involved, and where there still remains an uncertainty as to the legal rights of the contestants.

In the Rut.

In no branch of industrial life are men so prone to fall into routine in their work as in gold mining. The old-time methods, which have been used for years, are too often considered good enough, and the conservative gold-mill man complacently views his work and "falls into a rut." He becomes ultra-conservative, and in time looks with suspicion upon a new device with which he is unacquainted, and deprecates innovation of any kind. It is not so much, perhaps, the firm belief that no better work is possible than that being accomplished by himself or under his direction, as it is the thought of the disagreeable consequences of having it shown that for years he has been losing values that might have easily been saved had he been a little more flexible in his methods and a trifle less conservative in his ideas. If a reason for such a condition is sought, it will be found possibly that the production of gold is without competition. An ounce of pure gold has a fixed value in every civilized country in the world, and the gold miner's only competitor is the expense of production, and if, perchance, the mine is a dividend payer this only competitor is often considered as of small consequence. There have been as many innovations in the metallurgy of gold as in that of other metals, due to this competitor—expense. In copper, tin, lead, zinc and iron mining there is brisk competition, both at home and abroad, and he who seeks success in the production of base metals must needs keep well informed as to the best and latest improvements in the metallurgy of the metal he is producing. In copper smelting particularly has there been taken the most rapid strides, and here the most radical changes have been made, and the boldness of some of them is somewhat startling. The new superintendent of a large smelter sought to reduce the expense of matting. He found two large furnaces built in line with a considerable working space between. He drew the fires, cut the back end out of each furnace and constructed a central section similar to the remainder of the two furnaces, uniting them in one long furnace. The result of this previously unheard of innovation in furnace construction was the increasing of the capacity nearly 100%, in addition to which the gases from the furnace are utilized, furnishing several hundred horsepower.

The old-time mill man needs to bestir himself—the industrial world is moving, and moving rapidly, and he who fails to move with it will be left so far behind that it will be far more difficult to catch up than it is to keep up.

It is a good thing for the miner and metallurgist to travel about occasionally and to take notice of how things are done in other places by other men. It is true many are so situated that they cannot move about from place to place, and the only thing left for these is to keep informed by carefully reading the technical journals, which make a specialty of their line of work. In the best of these is found the latest of everything pertaining to mining and metallurgy, and they are indispensable to the man who seeks knowledge but cannot leave home to obtain it—they lift him "out of the rut."

THE Granby Mining Co. of British Columbia have been operating their large copper property on a liberal scale, and have demonstrated that a profit is possible in mining, transporting and reducing an ore containing 1.25% copper and less than $2 in gold and silver per ton. Of course this is only possible under very favorable circumstances, where the vein or ore deposit is of great size, and the ore of a kind requiring little or no foreign admixture of barren fluxing material, and where the fuel is cheap. Since such is the case it would seem that there may be more promising copper deposits of great possibilities than has been generally supposed.

Inaccuracies in Mill Sampling.

In many cases too much dependence is placed on rudely taken mill samples, and this dependence on an unreliable source of information is prolific of much friction between the mill superintendent and the home office. Those who have had experience in taking "grab" or "car samples," or samples from the ore bin chutes of the feeder hoppers, realize better than most others the inaccuracies incident to these methods. It cannot be said that it is impossible to take a fairly representative sample of ore as it passes along its journey from the stopes to the battery in the mill, for samples may be taken, which represent as accurately as it is possible for machinery to accomplish it, the value of the ore. The usual make-shift methods of grabbing a handful, a piece, or a shovelful at stated intervals, cannot be depended upon for results which are even approximately accurate. The ore as it comes from the mine consists of pieces which vary in size from particles which will pass a 100-mesh screen to masses weighing 100 pounds or more. In the average mill the run-of-mine rock is dumped on the grizzlies, the fine passes through and accumulates in one portion of the bin, while the harder coarse pieces are fed to the breaker and usually drop from the breaker jaws into another part of the bin beneath. The result of this practice is that some of the stamps continually receive the greater part of the fines, which may be either richer or poorer than the balance of the ore, and the coarse rock passes to other stamps. The cleanup shows the difference, as a rule, between the batteries working on hard rock and those crushing the fines. Hand samples from the several feeders must give differing results.

As the material varies somewhat in the relative quantity of fines to the amount of coarse rock produced, another element of uncertainty is introduced. These ordinary methods of taking head samples in the mill cannot possibly represent the average of values, and the bullion account generally proves this to be the fact.

Samples of headings can be taken with a very fair degree of accuracy, but to accomplish this the ore must all be crushed in breakers outside the mill, and both coarse and fine run together in the ore bin.

The rock thus crushed may then be taken from one point to another on a conveyor belt or bucket line, and a sample taken at stated short intervals. The amount taken during the day's run will be large—several hundred pounds, or possibly several tons, but accurate samples of large quantities of ore cannot be taken by cutting out a few shovelfuls.

The accumulated sample of the day's run, or the shift's run, can easily be quartered down in the sampling machinery, which should be an attachment of every well appointed mill, and an accurate sample thus obtained.

Another cause for discrepancy in estimates and results is the method of estimating tonnage by basing the estimate on the number of cars trammed into the mill. At some mills thousands of cars are trammed to the mill and not a car ever weighed. The cars are of standard dimensions and are supposed to hold a stated amount—usually about 2200 pounds, sometimes more—and occasionally the smaller mine cars are trammed into the mill. If all the rock be first broken to small size, say 2½ inch and smaller, the cars, if filled level full each time, would undoubtedly weigh very closely to a constant figure, but where coarse and fine are shoveled in indiscriminately, as is generally the case, or the ore is drawn from the bin at the mine, the weight per car will vary 200 to 300 pounds. A scale should be situated on the tramway at some convenient point and cars frequently weighed, or, if not rushed for time, the trammer should weigh each car.

With such a scheme for weighing and with proper methods of sampling, the value of each day's gross value in ore can be accurately determined. If it is impracticable to adopt the suggestions here made, it were better to discontinue sampling outside the mine entirely and look to the value of the mill tailings as a guide to operations, and the bullion output and the value in the tailings will give the gross value of the ore, but this information cannot be so quickly arrived at as by the adoption of the methods above suggested, which are not only reliable, but necessary where accurate information is required.

CONCENTRATES.

METALLIC MANGANESE is unknown in nature. It is manufactured from its oxide, pyrolusite, at considerable expense for laboratory purposes.

THE tin-bearing veins near Mount Wills, near Oneo, Gippsland, Victoria, Australia, were discovered by a Government prospecting party in 1888. They first found stream tin in the gulches and later found the veins by prospecting the adjoining mountain side.

THE necessary preparations for drainage should always be made in driving a tunnel, whether the tunnel be started in wet ground or not, for, if dry near the mouth, water may be found farther in, and if the grade is not sufficient the tunnel will be wet and sloppy, a condition in which there is no economy.

IN Canada a patent issued by that government is good for eighteen years. The patented device or idea must be applied and in actual use within three years from the date of issue of the patent. If a good cause can be shown for failure to use the patent, the time may be extended at the option of the patent office.

THE "salt cake process" of ore concentration as practiced at Broken Hill, New South Wales, Australia, is a patented process. Full particulars as to its application, with details, can be obtained from D. G. Delprat, manager Broken Hill Proprietary mine, Broken Hill, N. S. W. This process is the invention of Mr. Delprat.

THE tendency for grizzlies in quartz mills to become clogged may be reduced by spacing the bars at the lower end somewhat wider than at the upper end. This can be done either by having bars wider at the upper end than below or by using wider thimbles on the spacing bar at the lower end than those at the upper end.

IF a few drops of a solution of cobalt salt, or a small quantity of sesquioxide be added to a clear, concentrated aqueous solution of calcium chloride, which is then slowly heated, oxygen is evolved, the bleaching powder being wholly resolved into oxygen and calcium chloride according to the equation: $2CaCl_2O = O_2 + 2CaCl_2$.

A BELT SHIFTER should be placed near the driven pulley and on the slack side of the belt. A shifter composed of rollers, the length of which is twice the width of the belt, is better than a straight bar of wood or iron. The shifter should be set at an angle of 75° with the lay of the belt, or the edge will be badly worn by the repeated use.

BY a 10% grade is meant a rise or fall of 10 feet in every 100 feet of horizontal distance. If the distance be measured on the slope it will fall short of the horizontal distance, more or less, according to the percentage of the grade. In saying a grade of 500 feet to the mile, the mile measured on the slope is usually meant, and not the horizontal distance.

A MILLSITE cannot be entered by a stranger for the purpose of searching for mineral veins and ore deposits, for the reason that the person so doing is a trespasser. The law presupposes that a millsite is on non-mineral ground. A millsite may be taken up by a person owning no mine. Custom works are frequently located on government lands under the millsite law.

THE expedient of double roasting silver ores with salt—that is, roasting the ore with a small amount of salt, and then again roasting it with an additional amount—has been tried many years ago, and it was found by C. H. Aaron, who made experiments in this, that the losses sustained in the first roasting were repeated in the second, and no advantage was found in the double roasting.

IT is deemed by electrical engineers impossible to place conductors carrying high voltage currents of electricity underground. It is said were an attempt made to place wires carrying 50,000 volts underground an element of danger would be created. Greater safety is found in substantial poles or towers, with a distance between these supports, which has in it a sufficient factor for safety.

BY employing a sheet of gold as a positive electrode in a sulphuric or nitric acid solution, the gold will become tarnished brown, and if continued a reddish-brown powder will be precipitated to the bottom of the electrolyzing vessel. This is hydrate of gold, resulting from the oxidizing action of the electrolytically evolved oxygen. If this gold be collected, dried over sulphuric acid and heated, it will explode.

SOME ores are amenable to cyanide after roasting in the form of small lumps, the ore being rendered porous by the roasting of the sulphides. Also, some raw ores are susceptible of treatment by this process in lumps (as run through a breaker or rolls). An example of this is found in the gold ores of Camp Floyd (Mercur) district, Utah. Most ores have to be crushed fine, however, for successful treatment by cyanide.

THE use of the pneumatic hammer drill for mine sampling has been suggested and it would, in many instances, no doubt, prove an excellent method of obtaining samples, particularly where it was desired to cut a channel across a face of hard quartz. Work with hammer and moil on this kind of vein material is slow and wearisome at best, and here the pneumatic hammer would find a useful field for its operation.

ONE of the first deep channels to be opened by a bedrock tunnel in California was one of those under Table mountain, in Tuolumne county. This channel was very rich, but also exceedingly wet. Ross Browne stated in his report on the Mineral Resources of the United States, that in one place "10 feet square, superficial measurement, produced $100,000, and a pint of gravel not infrequently yielded a pound of gold.

MORE mistakes have been made in running drainage tunnels too high than too low. Particularly is this the case where tunnels have been driven to cut and drain old river beds. Whether a tunnel be run high or low for the drainage of a quartz mine simply means more or less ore, as the case may be; but a tunnel run to drain an ancient river, or any wet gravel deposit that proves to have been run too low, is practically useless for the purpose for which it was intended.

THERE are some mineral deposits known in the Grand canyon of the Colorado river. Silver-bearing lead ores are known near the mouth of Cataract canyon, and copper ores are found in various places in the schists of the Archæan, in the inner or lowest gorge of the Grand canyon. Copper is also found on the surface of the carboniferous limestone plateau through which the canyon has cut its way. These latter ores are very superficial in character and lie upon the surface for most part.

WHAT is known as No. 1 nitro powder contains 70% nitro glycerine, and No. 2 40%. In hard, tough rock No. 1 powder is advised, as greater force is generated by the explosion of this grade of powder, and the energy can be developed near the bottom of the hole. If many of the holes fail to break to the bottom, and if the remaining portion of the hole is a foot or more in depth, the holes are drilled to an unnecessary depth, as the powder fails to break them. Try shorter holes.

GOLD is known to occur in association with a great many minerals beside quartz. It is found in calcium carbonate (marble), with scarcely a trace of silica; in garnet, in hornblende and chlorite, in pegmatite dikes, in feldspar, jasper and sandstone; in quartzite, granite, diorite, rhyolite, and in an aggregate of mica scales; also in epidote, and associated with many ores, such as copper, lead, zinc, tin, antimony, quicksilver, iron, manganese, arsenic, selenium, tellurium, and other rare minerals. Aplite dikes are often payable in gold, and also basic dikes, such as diabase.

EXTENSIVE METAMORPHISM may occur in sedimentary and eruptive rocks along a contact, but such metamorphism is not necessarily an indication of ore deposition, although similar metamorphism may occur in connection with extensive ore deposits. The idea that a copper deposit is restricted in size and value because garnets occur in the accompanying wall rocks and within the ore deposit itself is a fallacy, for some of the largest and most profitable copper mines have extensive deposits of garnets. This is more frequently the case where one of the wall rocks is limestone.

A HYPOSULPHITE solution of silver chloride may be precipitated by the addition of sodium or calcium sulphide. When there is zinc in the ore being treated, if the zinc be in soluble form, due to imperfect roasting, the solutions become deteriorated, and the hyposulphite solution loses much of its solvent power, due to the accumulation of zinc hyposulphite in it, with a corresponding loss of sodium hyposulphite, the zinc hyposulphite being a non-solvent of silver chloride. If the zinc present be precipitated as carbonate by the addition of sodium carbonate, the sodium will unite with the sulphur, forming additional "hypo" to replace the zinc hyposulphite.

NO class of unpatented mineral locations is exempt from assessment work in the United States. And the assessment for next year can not be done in this. If it was not done last year and the claim has not been relocated by another, the work done now counts for this year alone as no assessment work is now required for last year. The title remains in the locator whether he performs the annual assessment or not, until the claim is entered by another and relocated because of the failure of the original locator to perform the necessary work. Then, under these circumstances, the title is transferred to the stranger and the former occupant has no longer a legal interest in the claim.

THE dip and strike of veins is rarely constant in any direction, as both change more or less in passing over a considerable distance—300 to 500 feet. There are no rules or laws governing the dip and strike of veins, and the direction is due to various causes, such as stress and torsion of rocks. Some veins have the normal dip changed by a falling over of the inclosing strata on the side of a mountain. Thus a vein which at the surface may have a dip to the westward, on an east hill slope, in depth may be found to dip eastward—its normal dip—the west dip near the surface being due to the formation having been overturned or folded by the weight of the mountain mass above.

PRODUCER GAS in metallurgy is not new. The use of producer gas was successfully introduced at the Marsac mill, Park City, Utah, by C. A. Stetefeldt, in 1890. At that time wood was used for fuel and the gas was used in firing two dryers and a Stetefeldt furnace. Coal was soon substituted for wood and it was found that the producer gas was not only more economical than other fuel, but that its use resulted in securing a better roast of the ore. Those contemplating the employment of producer gas should carefully investigate the coal to be used. A coal should be chosen the ash of which will only slightly slag upon being subjected to high temperature. The gas producer may then be run with little difficulty or loss of time from annoying stoppages.

IN iron moulding, fine, white, beach sand, free from iron, is used in making small, smooth castings, but for large castings a coarser and highly refractory sand is required, that is, a sand which will not be readily affected by the heat of the molten iron. In the use of coarse sand there is an opportunity for the gas to escape when the metal is being poured. No kind of sand wholly free from clay is suitable for moulding, for the sand will not be sufficiently coherent from merely moistening and ramming. Where sands are free from clay it is customary to add molasses, resin, flour, clay, glue or some other substance which will cause the sand to remain in the form in which it is moulded. Some sharp sands from beds of tuffa, such as rhyolite tuff, make good moulding sand.

WHEN amalgam is squeezed through a buckskin, canvas or other fabric in the cleanup room, it is a fact—well known to mill men—that some fine gold always passes through with the mercury, particularly where the gold in the ore is very fine. After standing for a time this gold will mostly settle at the bottom of the pot or bottle in which it may be placed. A simple method of securing this gold with the minimum amount of retorting is to take a 2-inch pipe about a foot long, to one end of which is screwed a cap. A hole should be bored through the pipe about 2 inches from the bottom, and this hole fitted with a suitable wooden plug. Into this the strained mercury should be poured and allowed to settle for several hours. Then upon withdrawing the plug the mercury above the top hole which contains little gold will flow out, leaving the enriched "quick" in the bottom of the pipe. This may be retorted and both gold and mercury recovered.

THE distance from the bottom of a shaft to which it is permissible to carry shaft timbers depends upon conditions. It is rather a question of how far shaft sinking may be carried ahead of the timbering. In some cases the timbers must be placed immediately the ground is cleared, and in running ground the lagging must be driven ahead of the main members of the set (forepoling). Where the ground is so soft as to require timbering to be carried very close to the bottom, it usually requires little powder, if any, to break the ground. On the Rand, in South Africa, the shaft sinking operations are sometimes carried as much as 150 feet ahead of timbering, the ore being raised in skips, guided by cables secured from the guides to the bottom where they are made fast to a bar fitted with a screw, like a drill bar, and with an arrangement to tighten the ropes, by turning a part of the bar. This gives security and permits very heavy blasting without danger to the timbers.

THE croppings of copper veins and deposits, as well as those of other minerals, are often deceptive as to the actual conditions below. This is particularly the case with copper, for the reason that copper sulphides are readily susceptible to the decomposing influences of the atmosphere, with the formation of new copper compounds, nearly all of which are considerably richer than the normal chalcopyrite. The copper sulphide on decomposing becomes sulphate, which is redeposited in a gradually enriched deposit. These secondary products of the decomposition of copper pyrite are chiefly chalcocite (copper glance), bornite (a rich copper sulphide), malachite and azurite (carbonates), and several varieties of black oxide, beside the richest of copper ores cuprite, the red oxide. The sulphate solutions may seep downward through the adjoining wall rocks of the original vein or deposit and form an enriched zone many feet in width, but upon carrying mining operations downward into the deposit, the enriched superficial deposit gradually grows poorer and eventually only the narrow original vein is left, which is too low grade or too small to longer afford profits from its exploitation. Another reason why large outcrops sometimes are deceptive is due to the disintegration of a mass of quartz, the country rock being softer and the scattering of the float and detached boulders over the hillside often causing a vein of moderate width to appear to be over 100 feet wide. The cause here is wholly mechanical, and due to disintegration of the vein and the scattering of its debris by gravity, and is a condition in which the chemistry of ore deposition and subsequent decomposition play no part. The prospector of experience can usually readily distinguish between these two phenomena, and acts according to his judgment in the matter.

Latent Mineral Possibilities of the Pacific Coast.

Written for the MINING AND SCIENTIFIC PRESS.

The existence of wonderful mineral resources throughout the United States has been shown by governmental and private enterprise, the development of the useful metalliferous minerals is being pushed by miners all over the country, but the complete utilization of many of the most valuable minerals is, as yet, in an embryonic stage. Germany, with its scientists, is pre-eminently the pioneer in this field, and as a consequence reaps a rich harvest from the sale of products refined from crude minerals obtained in the United States. While at present apparently of limited importance, yet this branch of mineral development is destined to take a leading place among the economic industries of the country.

Recent examples are found in the use of certain rare earths in the manufacture of incandescent mantles, the adoption of tantalum as a filament for the incandescent electric light, the demand for uranium minerals in the manufacture of radium, and the use of various metals and metallic oxides in the manufacture of high-grade tool steel.

The western portion of North America is particularly rich in the extent of its mineral resources, yet, except for the mining of gold, silver, copper, lead, zinc, fuel and iron and their by-products, and some quarrying of structural material, this great natural wealth is largely undeveloped.

In Colorado, molybdenite has been developed 1 mile east of Climax, Summit county, by H. Leal. The silver and iron ores of Lake county produce considerable manganese which is used in the manufacture of spiegeleisen, and also as a flux by the smelters. Colorado is also one of the chief sources of crude tungsten ores in the United States. Largely through the efforts of A. B. Frenzel of Denver the vanadium and uranium deposits of the State are likewise receiving some attention.

Wyoming is credited with producing asbestos, graphite, grindstones, metallic paint, platinum and tin. South Dakota has done but little in the development of these mineral resources beyond the work on its tin mines, and the shipment of considerable spodumene for its contained lithia minerals, and wolframite (iron-manganese tungstate), of which there is considerable in the tin regions.

Montana is attracting attention as an arsenic producer, as the output continues from the white arsenic plant at the Washoe copper smelter at Anaconda, which collects and condenses the arsenical fumes formed during roasting of copper ore. Near Dillon and near Ophir molybdenum deposits have been developed to some extent and at times some manganese ore has been produced. The grindstone industry is also receiving some attention. Idaho occasionally produces some cobalt ore.

Washington has been a leader in the production of arsenic. The Crown Point M. Co., in Chelan county, has marketed crystals of molybdenum, and a talc deposit has been worked 7 miles from Marblemount in Skagit county, by T. M. and E. H. Alvord. Graphite has been found near Bossburg. Besides some quicksilver and platinum, Oregon's contribution to the minerals under discussion has been borax, which is found at Chetco, Curry county, as priceite, occurring, according to Chas. G. Yale, as pockets in serpentine, and in Harney county, 130 miles north of Winnemucca, Nev., as borate of soda in marsh lands. Nevada, likewise, has produced some borax and also some quicksilver. A tungsten property near Osceola, White Pine county, has been slightly developed. Nevada and Utah are listed among the States producing sulphur. Utah is also credited with producing manganese ore, uranium, vanadium and sodium chloride.

In Arizona metallic arsenic has been found at Washington camp, in Santa Cruz county, in masses attached to the walls of small pockets in dolomitic limestone. At Troy the Troy Manhattan Copper Co. has done extensive work in developing and concentrating wulfenite as a source of molybdenum, as has also Chas. Eudall of Tucson, in the Mammoth mine, at Mammoth. Near Dragoon, Cochise county, the Primos Chemical Co. has been mining and concentrating hubnerite and scheelite, used in the manufacture of ferro-tungsten and metallic tungsten. Asbestos is being developed in the Grand Canyon of the Colorado.

The U. S. Geological Survey's report on the mineral resources of the United States, from which much of the data for this article has been obtained, credits California with a greater diversity of mineral products than any other State. This includes lithium minerals from San Diego county, asbestos from El Dorado, borax from San Bernardino, Lake, Tehama, Mono and Inyo counties; chromite from several counties; graphite from Sonoma county; infusorial earth, magnesite, from near Porterville, Tulare county; Chiles and Pope valleys, Napa county; Sanger, Fresno county; Placer county, Kern county, Santa Clara county, and at Red Mountain, Stanislaus county; manganese ores, metallic paint, platinum, pyrite, quicksilver, salt, talc and tripoli.

Further possibilities in the development of these resources is suggested by work of the students in the Department of Pharmacy of the University of California. Under the direction of Prof. Frank T. Green of San Francisco, each student was required to take some raw product from his home or district and make from it a series of compounds of industrial importance.

Tulare county is represented by magnesium salts, prepared from heavy magnesium carbonate. These included the sulphate, oxide, nitrate, borate, carbonate, chloride and oxalate, and were prepared by Todd Claubes. From the supposedly worthless alkali soil of Tulare's valleys, A. M. Shaddle prepared sodium sulphate and chloride.

From a stalactite from Amador county, J. Garibaldi prepared calcium benzoate, salicylate and carbonate. Inyo county's cuprite was the basis for magnificent crystals of copper sulphate. Copper ore from Monterey county furnished the iodide and nitrate. The Copper King mine, of Fresno county, gave F. M. Carter the material for making the oxalate, iodide, citrate and ammonium-sulphate. Colemanite from Death valley, Inyo county, furnished sodium borate, boric acid, magnesium borate, potassium borate and borate of chromium.

The iodide, the chloride and metallic mercury were manufactured from San Luis Obispo county's cinnabar. Tuolumne county's pyrite yielded a series of ferric salts, including the carbonate, phosphate, citrate, ferric-ammonia citrate and ferric-quinine citrate. Galena afforded the oxide, chloride, nitrate, sulphate and metallic form of lead.

B. R. Nichols utilized San Luis Obispo's chromite to prepare potassium dichromate and lead chromate. San Francisco's pyrolusite produced manganese carbonate and sulphate. From soapstone was made talcum powder by filtration and by sifting, and from sea water sodium chloride and sulphate.

Potassium carbonate, acetate, citrate and bromide were prepared from oak wood ashes; oxalic acid from sawdust, and stove polish and chain lubricant from graphite. Potassium bitartrate and potassium-sodium tartrate were prepared from crude argol by F. W. Pottle, who also prepared zinc sulphate, acetate oxide and carbonate from franklinite.

In addition to the above, numerous other commercial products were manufactured by the students from the raw materials afforded by the States—California, Oregon, Nevada, Arizona and Idaho. These have been appropriately labeled and placed in 2-ounce screw containers of glass, and the whole placed as an exhibit in the California building at the Lewis & Clark Exposition at Portland, Or. This exhibit, numbering over 200 samples, readily shows the possibilities that Pacific coast minerals offer for the production of an extended list of mineral substances daily used in chemical laboratories.

Mining at Goldfield, Nevada.

TO THE EDITOR:—The number of men working in the mines of Goldfield district is gradually increasing. Another helpful factor is the starting up of several mills, and their successful treatment of the local ores. Four mills are now at work, and two or three more are nearing completion. The Combination Mining Co.'s mill treats the ore by amalgamation, concentration, and cyaniding. The question of a water supply for the town is rather serious. The Rye Patch source, from which Tonopah is supplied, is the most promising, but the big expenses of plant and pipe line render the undertaking rather doubtful for the present. The railroad grading is practically completed to Goldfield, and as soon as the Tonopah road is broadened to standard gauge the rails on the Goldfield line will be laid. This is promised by the latter part of July. It is said that with the advent of the railroad freight rates will be fixed at such reasonable figures that $25 ores can be shipped and smelted, and still leave one-half the gross value to the shipper.

It is reported that the electric power line running from Bishop creek, in California, will be ready to furnish power by September 1st of this year. Advertised rates range from $12 to $20 per horse power per month. This would not be considered cheap power in most countries, but it discounts wood at $18 per cord. It will hardly replace gasoline for hoisting purposes, especially where plants are already installed; but the reduction plants will find it advantageous, no doubt, and its advent will be a benefit to the district.

The future of the camp is still a mooted question. It depends upon the developments in the mines. Wise mining men whose opinions are best worth having are not indulging in loud prophesying as yet. There are decidedly hopeful indications in some portions of the camp; there are less encouraging results of development in others. The geological formation is a new one to the mining men here, and each new development is watched with keen interest. As a rule the mines of the district are in good hands, and there is no lack of capital for properties showing merit, or even for properties whose only apparent merit lies in the fact that they are located somewhere within the mineralized zone. The camp is burdened with the usual number of "wild cats," some of which may possibly eventually prove to be mines, for anything in that line seems to be possible in the Goldfield district. There is no apparent method by which the public can be protected from this class of frauds, but the individual may protect himself by either securing reliable information or refusing to buy stock. Mining men in whose hands the future of the district lie are not only hopeful but confident. Their chief concern is not so much whether the veins go down as whether the values at lower depths will stand the increased expenses of finding the ore bodies and exploiting them. Only the actual work will determine that.

Goldfield, Nev., June 30. F. N. FLETCHER.

An Interesting Ore Deposit.

TO THE EDITOR:—On one of my trips to the Black Hills, S. D., while making an examination of a property not far from Ragged Top mountain, but farther to the southwest, I came upon what occurred to me to be a peculiar state of geological conditions, and not previously either having seen anything like it or having heard of any like condition, it occurred to me that it would be well enough to send you a little description of it.

The country where the observation was made is generally pretty flat but somewhat cut by deeply eroded canyons or ravines and waterways, leaving the intermediate spaces between these canyons much like flat-top mesas, which are more or less broken on the surface by dikes of trachyte, which generally run lengthwise with the mesas and seem to parallel the general direction of the waterways. At the edge of these canyons, which are generally precipitous, one can readily see the line of limestone capping which rests upon the slates and schists. I deem by some prior dynamic disturbance the lime capping was fractured and openings were made that later became the waterways, as the slates and schists are very soft and by the action of the elements have worn away very rapidly. The material next above the slate is limestone; its mean thickness is perhaps from 50 to 75 feet and in many places crops to the surface.

Now, the peculiar part that I wish to discuss is the ore deposit which is on top of the limestone. To me it seems it must have been deposited at the time of the upheaval of the large trachyte dike, which has folded the lime strata on each side of it, and the folds run parallel to the dike—the dike having a width of from 100 to 150 feet. It seems to have pushed the lime strata back and caused the folding, and at the time of this folding it has the appearance of having been covered by water and with no surface dikes. A portion of it appears to have been deposited as a mud, or rather a slaked lime solution which must have resulted from the heat and water during time of the molten eruption of the trachyte, and it settled in the bottom of these folds as ordinary mud would settle in low places from a high water overflow. I am aware that this theory—for such it is—will be combatted by some who will claim that the overflow came with the eruption, but I see one reason to combat this, and it is due to the fact that no debris, such as broken fragments of the trachyte or unslaked lime, is present in the sedimentary deposit. Now, as to the nature of the deposit, it shows plainly the action of heat, and especially is that true in the folds near the dike, as it shows in a good many places much of the lime rock, which is not a very high-grade lime, which is burned to a bright red brick color. The sedimentary deposit, however, is not so high colored, as its color is from light gray to brown, or yellowish brown, and a great part of it is chert of a light gray color and very closely resembles that found in the lead and zinc fields of Missouri and Kansas, and the lime somewhat resembles the limestone of that country also. Much of the sediment has taken the form of chalcedony, and not nearly so firm as the chert, and the strange thing is that these settling troughs have caught some gold and have values ranging from $6 to $12 per ton. On the top of this auriferous deposit is a covering of surface debris, and of all sorts of rock, and some very large quartz boulders among the other rock and dirt. The quartz has no connection in any way with the sedimentary deposit, as these pieces of quartz are all over the surface and are a very pretty fluorine stained quartz and also carry from $10 to $15 in gold, and no place has as yet been found where such quartz is discovered in place anywhere in the vicinity. The fact that there was no covering on or above the sedimentary deposit would show conclusively that it is not at all likely that the water, or values either, came from below.

I may state in conclusion that I reported unfavorably upon this property for my people, but since that time two other men have reported favorably, stating that the conclusions reached by myself regarding the folding of the lime strata were in error, and a 100-ton cyaniding mill has been erected to treat these ores, which are well adapted to this treatment and will stand ½-inch crushing, and an extraction of 85% and up is secured from this ore by the coarse crushing and a sixty-hour treatment. ENGINEER.

Denver, Colo., June 25.

How Some of California's Early Mines Were Worked.

Written for the MINING AND SCIENTIFIC PRESS.

In southern California many years ago were gold mines which were profitably worked, the history of which is now obscure, and the whereabouts of some of the mines is uncertain. In Los Angeles and Ventura counties particularly were there profitable mines, both quartz and placer. These mines were developed and operated for most part under the direction of the priests who were stationed at the missions in the neighborhood of the mines. The missions were established late in the eighteenth century, and some of them early in 1800. It may be said that they were in the height of their success from 1810 to 1840. It was during this period that the mines were worked for gold, and if the stories told by some of the old Spanish settlers can be relied upon, and there is no reason to discredit them, the result of these mining operations was satisfactory. Some of the Indians living at San Gabriel tell of rich gold and silver mines in the San Gabriel range, north of San Gabriel. It is a well known fact that a few miles up the San Gabriel canyon, from its mouth, is a system of silver veins which have been worked more or less within the past 20 years, and some of the ore was very rich in silver sulphide and native silver. Gold also is known in the San Gabriel canyon, both in quartz and placers. In the Tejunga canyon, near the head, about 40 miles northeast of Los Angeles, are gold-bearing veins, and on Mount Gleason, southwest of Acton Station, a quartz mill was in operation a few years since.

At the time when the missions of southern California were enjoying their greatest prosperity, when there were several hundred Indians attached to each, these had to be cared for in body as well as mind. In return for this support from the padres, the Indians became the friends of the missionaries and did what they could in the way of manual labor. Each spring the padres of San Buena Ventura and San Fernando missions, who had learned of the gold in the Castec and Piru canyons, sent Indians to work in the gravel deposits to secure such gold as they could by the primitive methods of those days. This was long before the discovery of gold at Coloma, in El Dorado county, the discovery which made more history than any discovery of gold either before or since. These Indians worked under the direction of Jose Bermudas, of the mission at Ventura, and Francisco Lopez, of the Mission San Fernando. The Indians worked these placers as long as water was available, and in some instances worked by dry blowing, using baskets to toss the dirt into the air, the lighter portion being blown away by the wind. By this means only the coarser gold was recovered, the fine usually being lost. Panning with the batea or wooden bowl was the favorite method of getting the gold. Each fall the several crews of Indians returned to the missions with considerable gold.

After the missions had been closed and their property confiscated by the Mexican authorities, and mining by the Indians came to an end, Bermudas and Lopez petitioned the Mexican government to set aside the territory between Piru creek, in Ventura county, and Soledad canyon, in Los Angeles county, and extending northward to Mojave desert, as a mineral district, and asked that no grant of land be made taking in any portion of this territory, and this the government did.

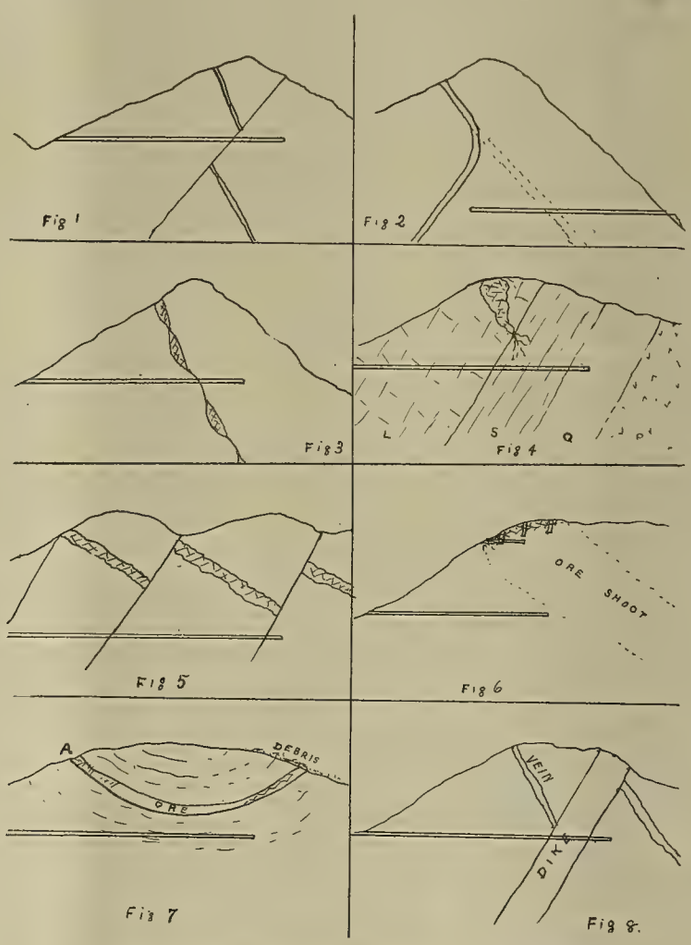
It is said that in 1854 there was considerable excitement in the district owing to a number of miners making handsome clean-ups that season. It was reported that a Mexican miner named Garcia took out in San Feliciana canyon over 200 pounds in gold nuggets, and a number of others got from $5000 to $20,000. These placers were superficial and quickly worked out. Four years later, in '58, other good strikes created another stampede, and 1500 men were mining there that season. Whether these old stories are true or not, there is scarcely a canyon or gulch in all the area extending from Soledad canyon northward to the desert and westward to Piru creek, and in the region south of Newhall, that hillsides and gulches do not show abundant evidence of extensive mining operations. Bars have been worked out, the gulches have been mined probably several times. Dry ravines have been turned over and over, as the heaps of cobbles piled alongside of the rocky beds attest. Numerous and lengthy ditches abound. Many of these are obscure, but they were undoubtedly ditches. In the stampede of 1858 many quartz veins were taken, and some of them were rich in gold, though "spotted." One man is credited with obtaining nearly $40,000, the quartz being beaten up with hammers, and the pulverized rock being washed in the batea, no amalgamation being practiced at that time. In the Fraser Mountain district are numerous gold veins, and in the region around Acton there are a score of old mines and numerous prospects. All the gulches heading into the mountains south of Soledad canyon prospect in gold, and large amounts of gold have been taken from Placerita canyon near Newhall. In upper Soledad, near Lang's, Southside, Ravenna and in that vicinity, there are great beds of conglomerate, and some believe the gold found in the gravels are derived from these conglomerates. This may be true, but the gold, if from the conglomerates, originally came from veins in older and underlying rocks. The region has been practically neglected for years, but it possesses much that is of geological and scientific interest, and careful prospecting by experienced men may discover some good paying mines in that district. Its principal drawback is lack of water. In the rainy season it is fairly abundant, but at other seasons of the year the canyons are dry and the region is little better than the desert.

Practical Mine Development.

There are numerous maxims familiar to miners, and these trite sayings are usually the result of experience—often of unfortunate experience. One of the most frequently heard of these sayings is, "follow your vein wherever it goes." Without doubt this advice has been suggested by the disastrous results financially sustained by some miners who left their vein to do systematic and methodical but ill-advised work, and whose purse was not "long" enough to accomplish the desired ultimate results. Without doubt it is good mining for the prospector whose means is limited to follow his vein by shaft or tunnel if he can. Many men in the first years of their mining experience, having found a promising prospect well up on the mountain side, think they can see an advantage in driving a crosscut tunnel several hundred feet below the outcrop of the vein, in order to get "backs," and save the expense of hoisting and pumping or bailing water. Very often this tunnel, the estimated length of which is usually several hundred feet, is started before much else has been done—perhaps not more than a fifty-foot hole has been sunk on the vein In a great many instances this is not good mining, as has been demonstrated by results There are too many uncertainties in vein formation, and in the distribution and value of ore deposits to justify uncertain and expensive development to reach veins or ore deposits which may not exist. When the development on the vein has been performed to an extent which will pay for the driving of a long tunnel, so that the miner is not out of pocket should he fail to find what he is seeking, it may be good business to undertake the long drainage tunnel through barren rock, but not before. In a far worse predicament is he who not only runs a long and expensive tunnel only to find his vein has not come down to that level, but also builds a mill or smelter in addition to the former folly.

The accompanying sketches illustrate some of the geological conditions which may result in a tunnel not finding an ore deposit or vein in depth which makes a good showing on the surface. To these might be added many others equally common and simple, and some far more perplexing in their structure.

Fig. 1 illustrates a very common occurrence—a vein displaced by a fault. The tunnel driven from near the base of the hill passes through the fault at a point where it is merely a seam in the rocks and misses the vein entirely, although it is both above and below it. Fig. 2 shows a vein deflected from its true dip by a fold in the country rock, which has carried the vein with it. The long tunnel has been driven far beyond the point where it was expected the vein would be found, and the funds of the owners being exhausted the work comes to a standstill—for a time at least. In Fig. 3 the vein is continuous, but where cut by the tunnel has dwindled to a seam of clay of knife-blade thinness and is passed through unnoticed, as there are other similar seams in the country rock. Fig. 4 shows a strong outcrop of lead-silver ore in limestone. The deposit dips regularly into the mountain, but on coming to a reef of slate the vein scatters, and the tunnel driven under the croppings fails to find anything. Fig. 5 shows a condition not uncommon in regions of sedimentary deposits, such as at Leadville, Colo. Here a series of faults have repeatedly dislocated the vein, and the tunnel finds nothing but barren rock. At Leadville



Diagrams Representing the Uncertainties of Vein Continuity,

the faulting is on such a grand scale that this difficulty has not been met with in many cases, but the principle is well illustrated. Fig. 6 is a case where a long tunnel has been driven on the vein, but the ore shoot pitching away from the tunnel, the owners become discouraged, or "broke," before the pay is reached. In Fig. 7 an anticlinal fold deceives the miners who found the outcrop at A. Debris covered the outcrop on the opposite side of the hill, and it was naturally supposed that the vein continued downward, as it had started at A. In Fig. 8 is shown a vein intersected and thrown by a dike. The tunnel driven in ignorance of this condition fails to find the vein, but enters and crosses the dike, discovering nothing on the opposite side. Each of these instances have practical illustrations many times over, and many others might be added to show the inadvisability of driving long tunnels to develop an ore body or vein of which but little is known at the surface, and particularly where the miner's means are limited.

Ammonia in the Cyanide Process.

Some experiments made by A. Jarman and E. L. Brereton, the results of which were published in the Transactions of the Institute of Mining and Metallurgy, showed that for quartzose gold ores containing cyanicides, particularly copper carbonate, ammonium cyanide is a more efficient solvent of the gold

than potassium cyanide alone, but not so good as the latter in presence of a small amount of ammonia. The amount of ammonia required to protect potassium cyanide solutions from dissolving large quantities of copper increases with the strength of the cyanide solution, but is not affected by the amount of copper up to 3%. With more than 3% of copper, a larger amount of ammonia is necessary to obtain a good extraction of the gold. With ores containing from 1.5% to 3% of copper, and with a 0.25% solution of potassium cyanide, the best extraction is effected in presence of 0.1% of ammonia. A mixture of ammonia and potassium cyanide can be prepared which dissolves less copper carbonate than either of the components alone; and the composition of this mixture is very near that of the solution which gives the best gold extraction (i. e., when using small percentages of ammonia). During the treatment the amount of dissolved copper first rapidly rises to a maximum, but afterwards diminishes steadily, while at the same time the quantity of gold dissolved increases.

Vertical Shaft Sinking on the Rand.*

NUMBER II.—CONCLUDED.

Mr. Bradford said: The figures which have been given us in relation to some of the deep shafts of the Rand, and those which are promised us by Mr. Simpson, are of very great interest. There is one thing, however, in connection with these figures which I would like to have seen stated. In the sinking of any developing shaft speed is worth more than it is in a mine which is already in operation, and consequently the cost per foot is not of such relative importance. All economies are of moment, but a mine can afford to pay a very high price per foot, sometimes, in order to reach its reef quickly. Now, in the figures which have been given us there is no statement as to the method of paying the men. You cannot get speed from any class of man—extra speed—on a mine without he is paid in proportion to it. And I should like to have the figures in reference to the bonus paid in these deep level shafts. I understand that the system of sinking in the case of the Jupiter (whether it is so on the Village Deep or Cinderella Deep I do not know) was to pay a very heavy bonus, and it would be of interest in connection with this paper to know just what these payments were. If you pay a man sufficiently you can get two days' work put into one. Mr. Roche, speaking of headgears, says rightly that they should be erected on first-rate foundations. I would add that they should have ample ore bin capacity and strength Many headgears on these fields have been built altogether too light and too small, and we are finding this out as the mines come to rapid pulling. These faults are being remedied in the headgears now going up, but if there is any error in the size of the bins, let them be too large rather than too small. Mr Roche goes on to speak of bearers in a shaft, but does not refer at all to the blocking, which is of vital importance. As I understand bearers, they are simply a safety catch for the timbering of a shaft. In other words, the blocking of a shaft should be so put in that it carries the weight of the timbers, leaving practically as little weight as possible to the bearers themselves. I presume it has been the experience of many mining men here who have gone over shafts to find the blocking sometimes looking down a shaft and sometimes perfectly straight; and I have seen some places where the blocking was against the studdles, or against the wall plate, midway between the dividers. This is all wrong. In a properly timbered shaft the blocking should be against the wall plate directly opposite the dividers and looking up the shaft, forming a series of trusses which should practically carry the weight of the timbering. I do not mean to say that you should not have bearers at regular and frequent intervals, but they should be for safety in the event of the pit work settling, and not primarily to carry its weight. With the blocking comes the question of hand sinking and machine sinking. In most machine sunk shafts here the walls are excessively rough. It is impossible to sink a clean wall with machines, and easy to do so in hand sinking; and a clean wall makes a great deal of difference with the blocking. In regard to kibbles and skips, I fully agree with Mr. Roche that skips are preferable. Very many of the fatal accidents which have occurred in deep level shafts sunk on these fields have been directly traceable to the use of kibbles. Where skips are used the danger to the lives of the men engaged in the work is greatly reduced. In the matter of the size of the machines, which has been touched on at some length in the discussion just read, I also heartily agree with Mr. Roche. I believe the more work you can get out of a machine that you have once got rigged the better. At the Wolhuter mine in 1902, where a record was made by T. J. Britten for inclined shaft sinking on these fields—and I think a world's record—the machines used were 3½-inch Sluggers. The method of sinking was to break everything to the center cut, drilling the face over to a depth of about 9 feet, with all but the side holes working toward the center. Mr. Britten once told me that he found it advantageous to miter out a short cut first. and when this had broken to fire the remaining holes; but I understand that later he found this unnecessary. In the Star of December 9, 1902, there is an account of this shaft, and I quote from it the following table, which shows what big drills can do, and is a record of excellent work:

SIZE OF SHAFT, 20 FEET BY 7 FEET 6 INCHES, 932 FEET BEING SUNK VERTICAL AND THEN TURNED ON THE UNDERLAY.

	Aug.	Sept.	Oct.	Nov.
Depth of shaft on first month (1902)..	1,115	1,294	1,476	1,680
Sunk during month	179	182	204	209
Number of days worked	31	30	31	30
Number of blasts per day	31	30	32	33
Average sunk per day	5.78	6.07	6.5+	6.97
Average number of holes per blast...	28	28	28	28
Depth of holes from 7 ft. to 9 ft. 6 in., average	8.17	8.5	8.5	8.5
Tons of rock broken and hauled per month	2,237.5	2,275	2,550	2,612.5
Tons of rock per daily blast	72.17	75.83	79.69	79.1
Tons of rock broken per drill per day.	18.04	18 96	19.92	19.77
Average number of drills employed..	4	4	4	4
Amount of gelatine used, cases.....	84	100	106	120
Gelatine used per blast	2.71	3.33	3 31	3.63
Average number of 1¼-in. cartridges per hole	7	8	8	8
Total pounds gelatine used	4,200	5,000	5,300	6,000
Pounds of gelatine per ton of rock broken	1.88	2.20	2.08	2 29
Average time of drilling per day....	12	12	12	12
Average time for clearing rock broken, hours	8	8	8	8

Price paid contractors, £6 per foot. Contractors employed and paid unskilled white machine helpers. Company cleared away all rock broken with white lashers, who were held ready to go down at any hour on signal.

Now, it seems to me that the same argument which applies to the use of big drills in incline shafts applies equally to vertical shaft sinking. If you are going to sink deep holes you must have long, heavy bits, and a big machine is essential to get the necessary pull back. You cannot sink deep holes with light steel, nor can you pull back heavy drills with a light machine.

As to the number of machines, I believe in working just as many as you have room for, because the great thing is to drill the shaft over as quickly as possible. Time is the essence of option. If time is lost in putting the drill holes down, it is lost straight through the month, and you cannot make it up. I do not agree with the writer as to the advisability of Cornish pumps for deep level shafts. High lift air or electrically driven pumps seem to me better adapted to the work, but in the matter of bratticing, instead of putting in ventilating pipes, I think he is quite right. In reference to the comparison of costs, he is also unquestionably right, because there are probably no two mines on these fields outside the same groups where costs are kept in exactly the same way. I remember an amusing story, told me once by the late Major Seymour about a certain headgear on these fields. The costs were particularly high, and when they came to investigate, among other things they found that a span of four mules and harness had been charged to the headgear.

In equipping a vertical shaft with hauling roads where the skip is to run around the turn at the foot of the vertical on to the incline, the general practice on these fields is to put in heavy T rail, carried on the wall plates, and either corresponding T rail or angle iron on the dividers. It is better to use all T rail than rail and angle iron, but it would be still better to do away with such roads altogether, and run the skip in the vertical either on steel or wood guides. The wear and tear would, in my opinion, be much less than with the present system. Certain experiments are now being made in this direction, and if they succeed we shall be able to run our incline skips through the vertical part of the shaft, exactly as the cage runs now, it being so arranged that the skip may leave its guides and take the angle irons at the turn. If this system can be perfected it will be economical, and will conduce to smoother running in the shafts. In the matter of fastening these guides, there is only one mine on these fields I know of which uses a center studdle at the back of the guides. When the Robinson Deep shaft was gone over and retimbered center studdles were put in. As a usual thing, wooden guides are bolted with through bolts to the dividers, so that at the ends of each length of guide the divider carries say four bolts when a guide is 8 inches by 4 inches, or two bolts if it is a 4-inch by 4-inch guide, whereas if a center studdle is used the guides, instead of being always joined at the dividers, are joined between them and bolted to the center studdle, as well as to the dividers, making a solid job from the top of the shaft to the bottom.

T. L. Carter remarked: I have not come prepared to say very much upon this paper, but I should like to raise three points, and one of them is well worth noting, for it will be an important matter in the future. It is the question of good workmanship versus speed in shaft sinking. It is desirable to get the shafts down in record time, but I think there are cases where it is better to make less speed and be surer of the work. Of course, I do not say you cannot have both speed and good workmanship, but if there is any doubt about the thoroughness of the work, I should let off a bit in sinking, timbering, etc. I have seen instances where mines have been hampered for years by shafts being a few inches out of vertical, due to timbers not being attended to properly. In 1896 a bad accident happened on the Rand, in which three white men were killed in a vertical shaft. It was found that the accident was due to slipshod workmanship in putting in the bearers when sinking the shaft. The shafts on a property correspond with the main arteries of the human body, and they are of vast importance in the future working of a mine. If they go wrong, of course, everything is absolutely hung up, and for this reason I think it is a matter worth thinking about to have everything about the shaft as permanent as possible. The preservation of timber, for instance, has reached a high stage, and it is a matter worth going into whether you should not "treat" the timbers before putting them into a shaft. The initial expense will be a little higher, but the final result will be better. The same argument holds good with headgears. The Rand is so well established that most of the mines in future will be mines whose lives will be twenty-five to thirty years. It seems to me a mistake to start off with a little tin pot headgear. It is a permanent affair and should last the life of the mine. For this reason I do not think we should ever use wooden ones at all in a mine of twenty-five or thirty years. We should have best steel headgears, and for the future we should think of no other. In the course of five or ten years a wooden headgear is almost rebuilt with patches here and there, while a steel headgear, although the initial cost is high, is a permanent structure and will last the full life of the mine. Too small bin space is allowed in many of the mines of the Rand, liberality in which is the best policy.

*Trans. Jour. Chem., Met. & Min. Soc., S. A.

Prospecting in the Desert.

With the coming of midsummer reports begin to reach the outside world of the hardships and loss of life on the great desert of southern California and Nevada. There are few people who have never been in that arid region who fully realize the discomforts, the hardships and the dangers attendant upon a trip through this desert in midsummer. The rains have ceased, the heat of day is indescribable, and it lasts far into the night. If it were not for the cool hours from about 11 P. M. to sunrise, which permits the denizens of that region to, in a measure, recuperate their energies, life would be unendurable there. Although after midnight it is almost invariably cool, eighteen hours out of twenty-four of each summer day are so hot that it is all that the average human being can do to exist through it, and yet there are thousands of men and women, and children, too, who have gone into that section within the past few months in the effort to snatch from opportunity a fortune as it whirls by in a cloud of heated desert sand and alkali.

Soon after sunrise the power of the sun makes itself felt. Metal expands and crackles like in a quickly heated stove as the sun's rays grow steadily hotter and hotter. By 7 o'clock in the morning the temperature has usually reached or passed the 100° mark, and shortly after midday it is not uncommon to see the thermometers register anywhere from 110° to 125° in the shade. The heat is dry, intensely dry, and this is the only salvation of the unfortunate beings who have, in most cases, voluntarily exposed themselves to this summer climate of the Great Basin region. Were there much of humidity in the atmosphere at such a temperature human existence would be impossible. The bright metallic glare of the midday sun is terrible, even to those who have for years been accustomed to it, but for those who cannot stand high temperatures, life on the desert in summer is a veritable hell on earth. If the lot of those who remain in the towns is thus made almost unbearable, what of the less fortunate prospectors who venture out into the hills or attempt to cross some scorching stretch of sand to reach the mountains on the opposite side — seemingly so near, but really a long day's journey and perhaps two, distant—for distant objects seem near on this southern desert? One may stand on a hilltop and gaze out across a desert valley in the center of which is a patch of clay colored earth, level as a floor — a dry lake, or perhaps it may be as white as the new fallen snow, due to the deposit of mineral salts on its surface. No object attracts the eye in this lonesome death-like valley. Take a powerful field glass and scan the desert closely, and perchance you will see two or three mere dots on the dry lake. Watch them and you see they are moving. Lower the glass and you discern nothing. The distance is too great—5 miles or more — and yet it seems less than a mile away. These moving dots are probably prospectors with their hardy little burros making haste to cross the valley to the hills beyond for the purpose of searching for a mine. Blistered by the scorching rays of the sun, tormented by the whirling clouds of dust and the eddying columns of alkali, these men plod slowly on to fortune, sometimes, more often to a hopeless ending of their dreams, and not infrequently to their death. Some imagine that with a canteen of water there is no danger on the desert, but such is not the case. Men die on the desert from other causes than lack of water. The intense heat drives

them to insanity and they wander from the trail and are lost. Canned goods are commonly used on the desert, but all who use this class of provisions should know and remember that having once opened a can of fruit, vegetables or meat, it should be removed at once into a crockery, glass or enameled vessel of some kind, for in the heat of that country ptomaine poison quickly develops in opened canned goods — particularly in those which contain acids, such as tomatoes, apricots, etc. Canned milk is also dangerous to leave in the cans when opened. The excessive use of salted meat should be avoided, although unfortunately this is about the only kind that can be carried about with the camp outfit. Bacon, ham, dried beef, canned corned beef, etc., are staples and are almost indispensable, but they should be used in moderation, for the liberal use of these meats only intensifies the thirst natural in this heated dry atmosphere. When stationed in a camp the water should be kept in a barrel or a canvas sack. The latter if hung up will keep the water several degrees cooler than the atmosphere. If the water is in canteens keep the outside covering of the canteens wet continually and put them in the sun, which will have a tendency to quickly dry out the moisture. The rapid evaporation lowers the temperature and cools the water. It is only due to this rapid evaporation of moisture that human beings, horses and other animals can exist under such conditions. No matter how freely one perspires the moisture is rapidly evaporated, and thus the heat is bearable. In the middle of the day it were better to rest and not attempt to travel. Experienced desert men make early and late journeys, resting for several hours during the middle of the day — from 11 A. M. to 4 P. M.—and where possible travel mostly at night.

Some think that the only really dangerous portion of the desert is in Death Valley, but the difference between the climatic conditions in that noted depression and in the region surrounding it is scarcely worth mentioning. The entire region is hot, dry and extremely dangerous to those unaccustomed to its terrors. The months of July and August are the hottest usually, and it would be well for strangers to the desert and its conditions to put off a contemplated journey to that region until October or November at least.

THE PROSPECTOR.

The white rock sample from Camborne, B. C., is marble of fine texture, and if found in large blocks, free from cracks and stains of iron, or other oxides, might prove on development to be a valuable structural and ornamental stone.

The samples from Isabella, Cal., are: No. 1, fine grained mica schist, somewhat silicified, and containing pyrite with possibly gold. No. 2 is a granular quartz rock in which is a considerable amount of iron oxide, both hematite and limonite. Rock of this description is sometimes gold bearing, but is usually extremely irregular in the distribution of values.

The rock samples from Grub Gulch, Cal., are: No. 1, grano-diorite; 2, mica-bearing diabase; 3, crystallized limestone; 4, felsite; 6, ankerite with scales of green mariposite; 7, black clay slate; 8, mica slate; 9, steatite (talc); 10, quartz, apparently a silicified hornblende slate. It is stained green by chlorite and contains pyrite, probably gold-bearing; 11, mispickel (arsenical iron sulphide) in quartz. It shows some gold; 12, pegmatite (granite); 13, diabase; 14, magnesite (magnesium carbonate).

The black rock samples from Althouse, Or., are white quartz containing 2% or 3% pyrite and a large percentage of magnetite (magnetic iron oxide). The rock is unusual in carrying magnetite and pyrite. The magnetite looks much like black manganese oxide, but the magnet will readily take up every particle of it.

The red mineral from Terlingua, Texas, is cinnabar; the white specimens are gypsum (calcium sulphate).

The mineral specimen from Bisbee, Ariz., is pumice and of good quality. Pumice is used as an abrasive material and is salable occasionally. A large amount of pumice is brought to the United States from the Hawaiian islands.

The rock samples from Prescott, Ariz., are: No. 1, andesite; 2, basalt; 3, quartz containing fine needle-like crystals of tourmaline; 4, cinnabar in iron ore; 5, quartz carrying scales of micaceous iron; 6, granite.

The rock sample from Daggett, Cal., is basalt. This rock is of volcanic origin and of comparatively recent age. The bottle green crystals in the black mass of the rock are crysolite (olivine). This mineral is abundant in some basalts and in other basic igneous rocks.

The rocks from Tybo, Nevada, are: No. 1, limestone; No. 2, chert; No. 3, rhyolite; No. 4, porphyry, possibly an altered rhyolite, too much decomposed for determination.

Ore Deposits of the Cœur d'Alene, Idaho.

Written by F. L. RANSOME.

One of the most important lead-silver producing districts of the world at present is that about Wardner, in the Cœur d'Alene district, Shoshone county, Idaho. The following abstracted from Bulletin 260 of the United States Geological Survey written by F. L. Ransome is the most important contribution to the geology of that important region, and is of interest to all miners who are learning to appreciate the value of a knowledge of geology as related to their ore deposits:

Although the Cœur d'Alene region of northern Idaho produces more argentiferous lead ore than any other district in the United States, its geological features are comparatively little known. Lindgren has published brief accounts of some of the mines and has described the principal mineralogical features of a few of the ores. Finlay has given a good general description of the lodes and mines, mainly from the technical standpoint, and has devoted about a page to the geology of the region. These are the only important publications relating to the geology of this part of Idaho that have appeared.

GEOGRAPHY.—The area which may be conveniently called the Cœur d'Alene district (although for purposes of record and administration it has been divided into a number of local mining districts) is, so far as its productive portion is concerned, in Shoshone county, Idaho. It lies almost entirely upon the western slope of the Cœur d'Alene mountains, a broad and rather complex member of the main Rocky mountain chain. The Cœur d'Alene mountains extend from Pend Oreille lake on the north to the headwaters of the North Fork of the Clearwater, or nearly to Lolo Pass, on the south. The eastern slope of the range descends in from 10 to 25 miles to the valleys of Clark Fork and the Missoula river. The western versant slopes as a broad, dissected plateau down to the basaltic plains of Spokane and eastern Washington. The breadth of this western slope is 50 or 60 miles.

Wallace, the principal town of the region and the seat of Shoshone county, has a population of about 3500. It is situated in the south central part of the district, at the confluence of Ninemile and Canyon creeks with the South Fork of Cœur d'Alene river. It is essentially a supply point for the mines, the mining population being housed for the most part in the smaller towns of Wardner, Mullan, Burke, Mace, Gem and Murray.

GENERAL CHARACTER AND DISTRIBUTION OF THE ROCKS.—The prevailing rocks of the Cœur d'Alene mountains are arenaceous and argillaceous sediments of great thickness. They constitute an apparently conformable series, of which neither the stratigraphic base nor top appears in the district nor, so far as known, in the surrounding region. No fossils have been found in them, and they are probably of Algonkian age.

On the west the sediments extend to Cœur d'Alene lake, where they are probably faulted down against the granitic and gneissic rocks forming the western shore of that picturesque body of water. On the north practically nothing is known of the extent of these Algonkian rocks. It is not unlikely that they continue northward past Pend Oreille lake and are connected with the great series of Algonkian beds known to occur in the northwestern corner of Montana. On the east, beds of the same character as those occurring in the Cœur d'Alene district extend to the Missoula river at the mouth of the St. Regis de Borgia. Here there is apparently some change in lithological character, but quartzites and red and green siliceous argillites, probably of Algonkian age, extend at least to the town of Missoula, in Montana, and probably for a distance farther east. The area of Algonkian sediments has a width of about 80 miles between Cœur d'Alene lake and the Missoula river, and it is probable that extensive exposures of Algonkian beds continue 100 or more miles to the eastward, connecting the Cœur d'Alene area with the known Algonkian areas of central and northern Montana.

On the south, Lindgren has shown that the sedimentary rocks near Lolo Pass, which are probably part of the same series that prevails in the Cœur d'Alene mountains, are cut off by the great granitic batholith of central Idaho.

In the Cœur d'Alene district alone, the Algonkian rocks have a thickness of at least 10,000 feet, and it is certain that by no means the entire series of rocks of this age developed in northwestern Montana is represented.

As a whole, the Algonkian sediments of the Cœur d'Alene region exhibit little lithological contrast. They are chiefly shallow water deposits, as shown by the prevalence of ripple marks and sun cracks They comprise dark argillites (mud rocks), graywackes (mud-sand rocks), quartzites of various degrees of coarseness, and usually sericitic, quartzitic sandstones, and impure limestones or calcareous argillites. Secondary cleavage is frequently present in all but the coarser arenaceous beds, but this slaty structure varies greatly in development in different parts of the field.

No sediments younger than the Algonkian occur in the Cœur d'Alene district, with the exception of fluviatile deposits, some of which may be of Tertiary age.

The Algonkian rocks are cut by a number of masses of syenite most of which have the form of small intrusive stocks, and by a few dikes of diabasic, dioritic, and minette-like habit, which have not yet been studied. The principal syenitic intrusions occur northeast of Wallace along a northeast-southwest line. There is no means of determining the age of these intrusions. If the syenitic stocks were intruded at the same time as the great granitic batholith of central Idaho, they are of post-Triassic and pre-Miocene age.

DIVISIONS AND LITHOLOGY OF THE SEDIMENTARY ROCKS.—Owing to the rather monotonous sequence of the Algonkian sediments, and the absence of fossils or unconformities, division of the group into distinct formations is difficult. Sands and silts accumulated on the subsiding bottom of a shallow sea to a thickness of over 10,000 feet. So shallow was this sea that most of the sediments retain the marks of pre-Cambrian ripples and were occasionally laid bare and cracked by the sun. Throughout the entire period of deposition there was no abrupt change in the general character of the sediments. Muddy silts graded into sands and these again into silts.

The Prichard slate is the thickest and the most homogeneous of the formations in the Cœur d'Alene district and occupies the greatest area. It is also one of the most distinctive, the regularly banded bluish-gray slates being readily recognized. It can be distinguished from certain somewhat similar beds in the Wallace formation by its noncalcareous character and by the fact that it weathers in reddish-brown tints, while the weathered exposures of the Wallace formation are yellowish gray. Slaty cleavage is usually fairly well developed and of a more regular character than in the younger formations of the district. It rarely obscures the bedding, to which it is usually inclined at considerable angles. In some places cleavage and bedding coincide, as in the excellent exposures by the roadside just east of Kellogg.

This formation is the prevalent rock along the South Fork from Kellogg to Osburn and occupies almost the entire drainage basin of Prichard creek. It is essentially the gold-bearing formation of the district, though it contains also some promising lead-silver veins, mainly in the transitional beds of its upper part.

The Burke formation consists principally of thin bedded, often shaly, fine grained, sericitic quartzites of prevailingly light tint. With these, however, are included some more massive quartzites, such as form the summit of Tiger Peak, and thin beds of grayish-purple argillaceous quartzite or graywacke. The latter are a more prominent feature of the Burke formation in the eastern part of the area than in the western part. Near the eastern border of the district these purplish-gray beds form the greater part of the upper portion of the Burke.

The Burke is not a very well-defined formation, as the thin-bedded sericitic quartzites and quartzitic shales that characterize it pass gradually downward into Prichard slate and gradually upward into the massive white quartzites of the Revett formation. It is, however, exceeding important from an economic standpoint as it contains the principal lead-silver deposits.

The formation is typically developed along Canyon creek from Burke to Gem, in the vicinity of Wardner, and in many other parts of the district, particularly along the eastern border.

The Revett quartzite is fairly homogeneous and is composed almost entirely of moderately thick beds of white or pale greenish-gray quartzite. The greenish tint is due to the presence of sericite, which forms a considerable part of some of the beds, while others consist of nearly white, pure quartzite. The softer sericitic beds are characteristic of the upper and lower parts of the formation and are in reality transition beds with reference to underlying and overlying formations. The thick white medial beds of the Revett quartzite are exposed chiefly in the eastern part of the district near the Idaho-Montana divide. They contain the copper deposit of the Snowstorm mine, and surround Lake Revett, whence the formation derives its name.

The St. Regis formation consists of siliceous shales or argillites, shaly sandstones, and impure, fine-grained quartzites, characterized throughout by features indicative of shallow water deposition, and by rather bright-green and purplish-gray tints. An irregular slaty cleavage is fairly common. The formation is far from uniform in aspect, however, and shows considerable lithological variation in different parts of the field. It contains beds not ordinarily distinguishable from certain beds in the Burke and Wallace formations, so that it is sometimes difficult to identify the formation when but small areas are exposed. The formation is thickest and best exposed in the southeastern part of the district, particularly about 3 miles northeast of Mullan and in the vicinity of St. Regis Pass.

The Wallace formation in thickness and areal extent is second only to the Prichard slate. It is the

most heterogeneous of all the formations distinguished. The dominant rocks are thin-bedded, light-green shales consisting chiefly of quartz and sericite, associated with impure limestones, bluish-gray argillites, and calcareous quartzites, and characterized from top to bottom by ripple marks and other evidences of shallow-water deposition. In addition to the dominant constituents, nearly all of the beds contain more or less calcite, dolomite, and siderite (or other ferruginous carbonates), which on weathering give a yellow tint to the exposures of the formation. A slaty structure is common, the rocks often being highly fissile, though the cleavage never approaches in regularity that of ordinary clay slate. Fresh surfaces of these green-banded slates have usually a peculiar waxy luster that is very characteristic of the Wallace formation, as is also the presence of carbonates.

The formation is well exposed at the town of Wallace, particularly at the Northern Pacific Railway station. It occupies large areas all along the southern border of the district, and is the principal rock along Beaver creek. The mines and prospects in the so-called "dry belt," between Wallace and Wardner, are mostly in the Wallace formation.

The Striped Peak formation is the least extensive in the district. The largest areas occur near the peak whence the formation derives its name. Lithologically it is almost a repetition of the St. Regis formation, with unusually abundant ripple marks.

IGNEOUS ROCKS. — The most important igneous masses in the district are the irregular stock-like intrusions of syenite. The typical rock of the larger areas, as determined by Mr. Calkins, is a coarse-grained syenite with a tendency toward porphyritic development of the dominant alkali-feldspar. The other essential constituents are plagioclase, amphibole, and pyroxene. Biotite is rare, and neither quartz nor nepheline has been detected. From this central type is considerable variation, particularly near the contacts and in the smaller masses, which consist usually of syenite porphyry. In the largest mass, near Gem, are found monzonitic facies and a number of interesting peripheral modifications rich in amphibole and pyroxene.

The larger syenitic intrusions are surrounded by well-marked zones or aureoles of contact metamorphism. The quartzites are altered to hornfels. The impure quartzites and argillites are recrystallized as aggregates of andalusite, garnet, sillimanite, biotite, muscovite quartz, and feldspar, and in the calcareous Wallace beds amphibole and pyroxene are developed.

The dike rocks of the region, which seem to have no direct connection with the syenitic intrusions, are not of great structural or economic importance. They have not yet been carefully studied, but will be described by Mr. Calkins in the final report on the district.

STRUCTURAL FEATURES OF THE DISTRICT.—The sedimentary rocks of the Cœur d'Alene district have been complexly folded, the folds in several instances being overturned, so that the older formations overlie the younger. They have also been extensively faulted and so strongly compressed as to develop slaty cleavage in all but the massive quartzites. While the prevalent strike of the beds is northwesterly, it is plain that no simple compression along northeast-southwest lines can satisfactorily account for the often highly complex character of the folds and the numerous and important deviations from the dominant northwesterly strike. In the greater part of that portion of the district lying south of the South Fork the strike is about west-northwest, and the axes of the major folds are traceable for considerable distances. In the vicinity of Kellogg peak and Wardner, however, the strike becomes more northerly and the folds more irregular. In the region lying north of the South Fork and west of Beaver and Nine Mile creeks the essential structure is that of an anticline, with a steep pitch to the north. The oldest formation exposed in this anticline is the Prichard slate, which occurs along the South Fork from Osburn westward, and in consequence of this structure forms a semicircular area north of the river.

From Mullan northward past Murray is a broad belt of close and complex folding in which north-south strikes prevail. This structure passes into a zone of more open folds to the east.

The region contains a number of important faults, of which the majority strike nearly west-northwest. Both normal and reversed faults occur, the dip of the reversed faults being usually steep. The west-northwest faults are particularly abundant in the southern part of the district, where seven important dislocations of this group have been mapped and studied by Mr. Calkins. These have throws of from 1000 to at least 4000 feet and observed lengths up to 18 miles. The most prominent fault of this group extends from a point east of Mullan, past Wallace, through Osburn, and for an unknown distance west of Wardner. The fault is normal, with downthrow to the south, and the dislocation brings the Wallace formation against the Prichard slate, near Osburn—a relation that implies a throw of at least 4000 feet.

The west-northwest faults have approximately the same general strike as the lead-silver lodes and were produced by the same or similar stresses. That some of the faults were formed prior to the deposition of the ore is fairly certain.

In addition to the west-northwest faults there are several dislocations of nearly north-south trend, which attain their greatest structural importance in the central part of the district. The most prominent member of this group is the Dobson Pass fault, which has been traced from a point about 3 miles north of Wallace to within 2 miles of Eagle. The fault dips to the west at an angle of 35° or less, and is normal. At Dobson Pass, 5 miles north of Murray, the fault has dropped the Striped Peak formation against the Prichard slate, indicating a throw of at least 6000 feet.

Another great dislocation of this group is the Carpenter Gulch fault, which has been followed from the northern boundary of the district southward, past the mouths of Prichard and Beaver creeks, for 12 miles to a point about 3 miles northwest of Wallace. Its course is irregular and it dips west and southwest at a moderate angle. This fault is an overthrust of approximately 1000 feet.

Slaty cleavage, usually of a rather irregular character, is a well-marked structural feature of the finer grained rocks of the Cœur d'Alene region, and a distinct fissility has in some places been produced in moderately coarse quartzites. It is best developed in the Prichard slate and in the lower part of the Wallace formation. This cleavage is usually independent of bedding, and shows a marked tendency to conform in strike to the general trend of the longer folds and in both strike and dip to the major faults. Local zones of slaty cleavage are the usual accompaniments of the lead-silver lodes of Mullan and Canyon creek. In no case does this structure attain the perfection found in roofing slate. The cleavage surfaces intersect at small angles, and the rocks split somewhat irregularly into lenticular flakes. The dip of the cleavage nearly everywhere ranges from southwestward to southward or westward.

(TO BE CONTINUED.)

Discovery and Development of the Homestake Mines of South Dakota.

NUMBER IV.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS.

The adoption of the room and pillar method of removing ore was eminently satisfactory from every point of view, except that it did not remedy the heavy expense of timbering. It had been the custom in these mines for years to drive great headings in advance of the stopes, and in which no timbers at all were placed. So solid were the walls that it was not unusual to see these cuttings 100 feet long, 40 to 50 feet wide and 30 feet high. On the floor tracks were laid and cars were trammed to the working faces, and the ore broken down was shoveled into the cars and trammed to the nearest shaft. The excellent standing qualities of the ground no doubt suggested the idea of mining without timbers. The miners were well aware, from experience, that there was a limit to the extent to which this idea of great timberless headings could be carried, and therefore had to devise a method of stoping which would permit the removal of ore in safety, and not result eventually in a cave.

A method was finally adopted known as the Homestake system. As in the method last described, the stopes are opened in series, stopes and pillars alternating, and sills are laid on the floors of the rooms in the same manner as in timbered stopes. Concerning this new method of stoping, B. C. Yates says in a paper devoted to the subject:

When the sills are in, three lines of track are laid running lengthwise of the stope, but crossing the ledge, with as many cross tracks connecting them as are necessary. The sill floor posts are put up and lagging placed over the top. The tracks are protected by double lagging on top and the rock is prevented from running in at the sides onto the tracks by lagging or slabs spiked to the posts.

As soon as the timber is in position the mining operation begins. The ore is broken down and allowed to fall through the lagging, entirely filling the sill floor sets, with the exception of the carways The lagging, which serves merely as a staging, is removed as fast as the sets are filled with broken ore. No rock is removed from the stope until this filling is finished. When the next cut or breast is carried across the stope some ore must be removed to make room for the miner. The timbers are carried only one set high.

In the large stopes two D-24 Ingersoll machines are employed, with from one to two "baby" machines, which are used to drill block holes in the large boulders.

Somewhat of an innovation in machine drills for block holing has been introduced. A small pneumatic hammer, such as is used in shops for chipping and caulking, fitted with a rotating movement, operates a small drill bit about 1 inch in diameter. This machine will drill holes from 6 inches to 12 inches deep and has so far proven very successful in block-holing large boulders in the open stopes.

As there are no timbers to break, no limit is placed on the miner as to the amount of rock he may bring down at one blast. The stope should be finished as quickly as possible so that the broken rock may all be removed if needed. Consequently large slabs of ore are blasted down, and these must be broken up to regular car size, either on top of the pile or on the sill floor as it is drawn down by the shovelers.

On account of the uneven size of the rock, chutes are not generally used in these stopes, but the car men shovel the ore into cars from the level of the track, there being as many places to shovel from as there are spaces between posts along the track. However, where the rock is soft and where it breaks fine, chutes are used to advantage.

Should a large rock come down which the shoveler cannot break with a rock hammer, he moves his car to another opening until the "block holer" comes around.

Two or three regular sets on each side of the stope are carried up as fast as the stope is worked, in which are placed the ladders and air pipes. These open sets also assist in ventilating the stope.

When the stope is worked up 80 or 85 feet, raises are made to the level above, through which the filling is to be dumped, and the ore is then drawn out. While the ore is being drawn out the walls and roof are carefully watched and all loose material is dressed down. No accident of a serious nature has occurred in one of these stopes during the two years in which this method has been employed that could in any way be attributed to the method.

When one end has been emptied of ore a section of the sill floor is lagged and the filling is dumped in until it begins to run over the lagging. In this way the filling follows the shovelers and the walls of the stope are supported at one end by the ore and at the other by the waste.

When small ore bodies are worked by this method no pillars are left in, but when one section is worked up a sufficient height another section is started at one end, and the ore is left until the entire body is worked.

Stoping without timber is not confined to the Homestake mine, but there are certain features of the method as employed here peculiar to the Homestake, and which are considered necessary to suit the conditions. In the Treadwell mine, Alaska, the sill floor is not opened on the station level, but drifts are run in the ledge and raises put up from these drifts to a level some 15 feet above.

No timber is required except for chutes, but a back of ore is left in, which takes the place of the sill floor timbers used in the Homestake. The cost of the timber would, in a great measure, be offset by the cost of making raises and putting in chutes. The accessibility of the ore is another advantage in favor of the Homestake method and becomes a necessity in a mine which furnishes nearly 4000 tons of ore every twenty-four hours.

As only a small per cent of the ore can be removed before the stope is finished, there is of necessity a large reserve always on hand, which allows the mine to lay off whenever desirable. The present broken ore reserve of the mine is nearly one million tons.

Timbering at the Mount Rex Tin Mine, Ben Lomond, Tasmania.*

Written by MARK IRELAND.

The ore body being worked is about 100 feet in length by 70 feet in width. A face of about 15 feet is stoped over the whole level at one operation, this height standing without any timber.

Double lines of logs, 20 feet in length and from 10 inches to 1 foot in thickness at the small end, are then laid longitudinally, butt to butt, and breaking joint from end to end of the ore body; they are at 10 feet centers from wall to wall. The starting logs are single for the first 10 feet and their ends are hitched into the solid rock. These are called "runners" and are the logs which are picked up as the level underneath is worked up. The double layer gives a better chance of picking up. Logs are now laid from the center of the ore body at right angles to the runners, the ends being hitched into the walls. A space, 7 feet wide, is left open right through the center of the ore body, and a similar space through from the cross-cut leading to the shaft. The cross logs are spiked down 4 feet apart to the runners. Decking of small spars from 3 to 6 inches thick is then laid down. Timber cribs, or pig-styes, are now built up, 4 feet wide, on each side of the open spaces previously referred to, forming a skeleton drive. The pig-styes are constructed as follows: Two logs are laid parallel, 4 feet apart, and upon them in notches at the ends and the middle, three cross-sills are laid, two more logs are laid upon them in turn, and so on until 7 feet high in the clear is obtained. In the spaces between the logs waste rock is filled in as fast as built. Strong caps, 12 to 14-inch timber, are then laid 4 feet apart across from pig-stye to pig-stye. Decking is laid over these caps as on the level. Shoots and traveling ways are then built, and the level is then ready for filling in with waste sent down from the surface. This method is strong and very cheap as compared with the square sets. But little dressing is required, an axe, saw and auger only being required, and any rough but fairly straight timber will do. An additional advantage is that no blasting, however heavy, can injure it.

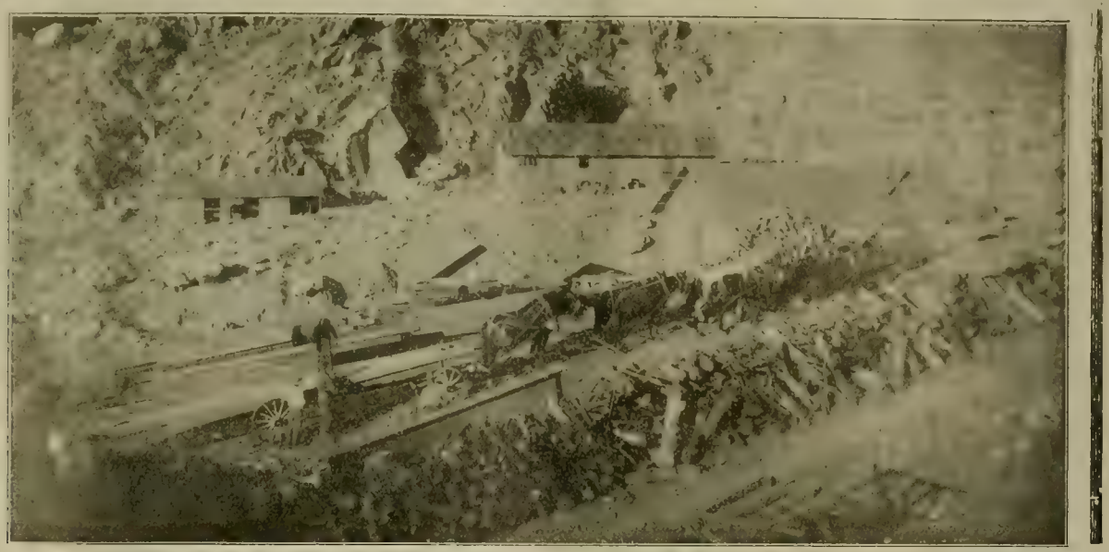
The Panamint Mining District of California.

In the news section of this issue is a communication from Panamint district, California, which at this time is again beginning to attract attention. This is one of the high desert ranges in southern Inyo county, and is in many respects more favored in climatic conditions than some of the other desert ranges of lower altitude. The large number of prospectors going into this only partially prospected district is likely to result in the discovery of valuable mineral deposits. The men now scouring the Panamint range are really the overflow from the crowded new camps of southern Nevada, and many of them who dread the intense heat and the dangers of the lower hills are contented to search in this higher mountain range where the heat, though intense, is still bearable. In Bulletin 208 of the United States Geological Survey, J. E. Spurr thus describes, in part, the geology of the Panamint range:



Hauling Lumber Into Panamint, Cal.

The Panamint range is one of the most important of the ranges auxiliary to the Sierra Nevada, which lie in the belt east of it, and runs northeast and southwest parallel to its front. The range is about 130 miles in length. At its northern end it merges into lava flows, which unite with the northern end of the Grapevine range, while at its southern end it passes into low hills of Tertiary (later) strata and associated lavas capped by later basic volcanics. It forms the southwestern barrier of Death valley, which it fronts with a steep slope. This range has been very little explored and not much is known concerning its geology.

On the east front of the range, above the road from Furnace creek, in Death valley, to the crossing of the range at Wing Gap, a large portion of the range consists of the older stratified rocks, which seem to lie beneath unturned Tertiary (later sediments and associated volcanics), and are cut through by masses of intrusive granite. The drift shows them to be in part finely crystalline blue limestone, and in part quartzite, white, grey, or green, often considerably altered and often coarse grained. The amount of quartzite in the drift implies a considerable thickness of this rock and suggests that the strata are of Cambrian age, as this is the only division of the Paleozoic in this region which contains great amounts of quartzite.

From this neighborhood northward the Panamint range is composed chiefly of old Paleozoic stratified rocks till near its northern end, as can be plainly seen from Death valley. H. W. Fairbanks found on the western side of the range, north of Windy Gap, as far as the Pinto range (which is a spur of the Panamint range running northwesterly from the Wild Rose mining district), that a portion of the rocks are mica schists, quartzites and marbles, which have been cut by intrusive granite. The strike of the folds is parallel with the trend of the range, so that unless disturbed by cross faulting the same general formation will be found for many miles. Therefore the Cambrian and Silurian have been represented as extending northward until covered by volcanic flows at the northern end of the range. The eastern flanks of the range fronting Death valley, as seen on the road between Furnace creek and Windy Gap, are composed of upturned, yellow-green strata and associated volcanics lying upon the older rocks with no evident unconformity and partaking of their folds. This belt of interbedded volcanics and sediments grows wider toward the south. The same series occurs along a great part of the road which crosses the range to Windy Gap. The lava in these belts proved, in three different samples, to be andesite.

This series of conglomerates, breccias, tufts, chemical precipitates and lavas is the same as that exposed on the opposite side of Death valley, where it forms practically the whole mass of the Funeral mountains. In the Funeral mountains these rocks have been provisionally correlated with the Esmeralda formation in the Silver Peak range.

In the southern portion of the range the core of the mountains for some distance is made up of a body of massive granite, which varies to granite-porphyry; the granite, which cuts the ancient limestones and quartzites in the mining regions on the east side of the Panamint, is a hornblende-granite with much quartz.

As already stated, volcanic rocks make up a considerable portion of the Tertiary formations. Three specimens of these rocks examined all proved to be andesite, but probably other rocks occurred in these series. Overlying these older lavas unconformably is a later flow of more basic rocks, which cover a considerable area in the neighborhood south of Windy Gap. Mr. Fairbanks states that on the northern slopes of the Panamint range, overlooking Mesquite valley, there are scattered sheets of andesite and basalt. Yet another series of volcanics is exposed in this region. It is that forming the greater part of the Slate range, which lies immediately west of the southern end of the Panamint range. The highest portion of the Panamint range for a number of miles east of Panamint, a body of ancient rhyolite, is regarded as one of the most ancient lavas observed in the region. The northern end of the Panamint range, the Paleozoic rocks, are here covered by extensive flows of lava, which appears to be nearly continuous with the lava area at the extreme southwestern portion of the Silver Peak range.

A Mining Camp in Panamint Range, Cal.

Structure.—That portion of the Panamint range between a point opposite Furnace creek and Windy Gap appears in general anticlinal. There is here a series of alternating anticlines and synclines, having trends due north and south. Each of these folds may be traced continuously for a number of miles. The explanation of this phenomenon may be a series of east-west faults, which fault the folds systematically to the east on the south side. In the Panamint range much of the deformation must be of comparatively recent date. We know much of it occurred since the deposition of the Tertiary beds and associated lavas.

Near Postoffice Springs, H. W. Fairbanks describes gold deposits occurring in folded limestone strata, with slates below and on both sides. The ore is high grade. Near the old town of Panamint is found sil-

ver-bearing sulphide copper ores, with arsenic and antimony. The veins are found in all the sedimentary rocks of the district. In the Wild Rose district similar ores are found.

Panamint is one of the oldest mining districts in Inyo county. It is 70 miles southwest of Bullfrog and about 130 miles due south of Goldfield, Nev. The town of Ballarat is located in the Panamint valley, 63 miles from Randsburg, which is on the Santa Fe Railroad. The district is easily accessible from the different railroad terminals of Keeler, on the Carson & Colorado, and Randsburg, on the Santa Fe.

There are streams of running water in the canyons, always enough for milling purposes and in many cases for power, and forests of pinion pine are to be found near the summit of the range.

The town of Panamint is on the west side of the range, near the head of several large canyons, at an altitude of 6000 feet, and at this place, in the early 70's, a large silver mill was built with a Stetefeldt furnace attachment for roasting the base ores. The mill was destroyed by fire, since which time, until the present, little attention has been given it.

Reclaiming of Bouldin Island, Cal.*

Written for the MINING AND SCIENTIFIC PRESS by JOHN A. YEATMAN, M. E.

An engineer glories in overcoming adverse conditions presented by nature. A detailed account of such work suggests by analogy how other difficulties that perplex the engineer may be met. Mining engineers may learn much for their own use by reading of the engineering achievements of their fellows. Much reclamation work is being done on the Pacific coast, but the following is believed to be unique.—ED.

The annual spring flood waters of the Sacramento and San Joaquin rivers of California are well known. The soil of the lower Sacramento valley is light and unsuited when formed into embankment to resist the force of these streams during flood season. During the past twenty years there has hardly been a year that one or more of these delta islands have not been completely submerged. The flood waters of 1904 reached their highest level in the latter part of March, with the result that Bouldin island, Tyler island, Stattin island and Edwards island, containing 31,000 acres, were submerged, besides twice this acreage on the lower San Joaquin, which was not in such a high state of cultivation. The loss, measured in reconstructive cost and pumping on these three islands, amounted to about $800,000, together with the loss of one year's crop and the unmeasured sum of restoring the land to its former state of cultivation. On March 23, 1904, after contending with flood water for four days, the embankment near Central Landing, on Bouldin island, in a bend of the Mokelumne river, near where it joins the San Joaquin river, gave way, undulating the entire island of 7000 acres to a depth ranging from 7 to 12 feet.

This break is one of more than ordinary interest, owing to the fact that a part of the embankment was routed out to a depth of 97 feet below the river level. After the water started over the embankment, the opening continued to widen until it had reached a width of 700 feet, 400 feet of which consisted only of the surface levee, being washed away; the remaining 300 feet covered the real rupture to the depth of 97 feet, the bottom being defined by a stratum of clay.

Within a week the water had subsided sufficiently to begin the work of reconstructing the levee (repairing the break). The first attempt was made after the regular manner of repairing levee breaks on the river. This being a larger break than usual, seven dredgers were engaged, two of them being suction dredgers, an aggregation of 750 H. P.; the other four dredgers were clam-shell type, having 2½ cubic yard buckets. Night and day for thirty days these dredgers poured their material into the break, the result being that the 400 feet of levee on each side of the break proper was restored; the depth to bottom of break was now 85 feet and no increased effort could decrease this. As the current washed through and carried the material inward and as the tide went out the waters retreated, to have the operation repeated the next day. Further effort along these lines being futile, it was decided to change the method of operation. Accordingly, two floating pile drivers and two hundred 100-foot piles were secured, including three barge loads of brush mats. Two clam-shell dredgers were retained. In this second effort it was proposed to drive pipes in bents of six piles each every 10 feet apart across the break to sink brush mats, which would be held in place, in part, by the piles, thereby breaking the flow of the sub-surface currents, that material might be deposited and remain. Night and day gangs worked at this breach of 300 feet until the season was so far advanced that it became evident that the annual crop could not be recovered. Work progressed from each end with fair success until the last 60 feet was reached, when it was found that the current was so swift—due to the contracted passage—the depth so great and the supporting surface for the piles so meager that all hope of closing the same by this method had to be abandoned. Piles 14 inches in diameter, 100 feet long, driven into 10 feet of sand and into a stiff clay strata and anchored at the top, were readily torn away by returning current after a tide. This second effort occupied about three months, and, while not successful, was contributing to the final closing of the break.

In the third effort it was decided that nothing but rock would ever baffle this current. Accordingly plans were made to lay a base of 80 feet, and as the deposit increased in height to make it narrower. Contracts were made for rock and hauling and the work began. As the nearest available quarry was some 30 miles away, and a large barge load was such a small portion of the embankment to be made, the reader can form some idea of the cost and magnitude of the undertaking. About the time the first 20 feet of the base was in place it was decided to secure an unworthy sea-going ship of 25 feet beam and 250 feet in length to sink across the break, to intercept the current and assist in filling. The ship was secured and sunk on the island side of the break. The feat was accomplished with dispatch and success. From an engineering point of view, it is a question whether the results justified the use.

Depositing rock continued until within 40 feet of the surface, when, to expedite the work that a second year's crop might be secured, it was decided to drive two rows of piling 10 feet apart and fill in the intervening space with rock, thereby reducing the amount to one-third of what it was estimated was yet required. Work of piling was begun on each side and the filling followed after, when the piling was brought within 25 feet of each other. No further piles were driven until the rock work was well carried forward and brought up to 7 to 10 feet below the surface, when it was discovered that the current was so strong as to be actually able to carry the rock away. This was overcome by depositing the rock in a diagonal manner, so that the water could not enter except by reverse current, and in this manner the work proceeded until in November, 1904, eight months after the break, the same was closed and the river excluded. Suction dredgers were again set at work and reinforced the rim of rock embankment. Pile work now proceeded to reinforce the material that had been put in place and to provide foundations for the largest reclamation pumping plant ever placed on the river.

The break being repaired and the 20 miles of levee around the island being in condition to resist the external waters, the work of removing the water from the island was undertaken. It was estimated that the water to be handled was between fifteen and sixteen billion gallons. The height to which it was to be raised was from zero at initial pumping to 12 feet maximum, with a possible 16 feet at high tide. The average pumping head for the entire mass of this water would be about 5 feet.

The time apportioned to accomplish this work was limited to sixty days. There were several reasons why the time was so limited. Chief among these were that it was necessary to remove the water by March 1, 1905, that the 1905 crop would be available; further, it was desirable that the final pumping be done quickly, that the sun would not heat up the water and sicken the asparagus plants. Accordingly purchase was made of four large centrifugal pumps, to be direct connected to short-stroke, cross-compound, high-speed engines, and contract was made with the United Iron Works of San Francisco, Cal., for the installation of the same. Owing to the unstable condition of the embankment, where it was

*See illustration front page.

necessary to place the pumping plant to most effectively drain the island, it was a matter of first importance to drive additional piles for foundation In addition to the many piles already driven, it was necessary to pile an additional area of 60x120 feet, and, upon examination, it was decided that, by using mechanically balanced engines, piles spaced 10 feet each way, securely capped and cross-capped, would afford ample stability to carry the load and resist the vibration. Such a foundation was prepared and proved to be all that was required.

Heretofore all the large pumping plants have been placed on the island side of the levee and have been placed so low as to permit the discharge pipes to pass through the embankment. This was impossible in this instance, as the water on the island was on a level with the water without. To cofferdam and provide a place was impossible, and the only thing to do was to install syphon plants, as illustrated herewith. This was the motive that characterized the hydraulic arrangement, and the same proved to be a money saver and an ideal arrangement, insuring safety and facilitating the installation of the machinery.

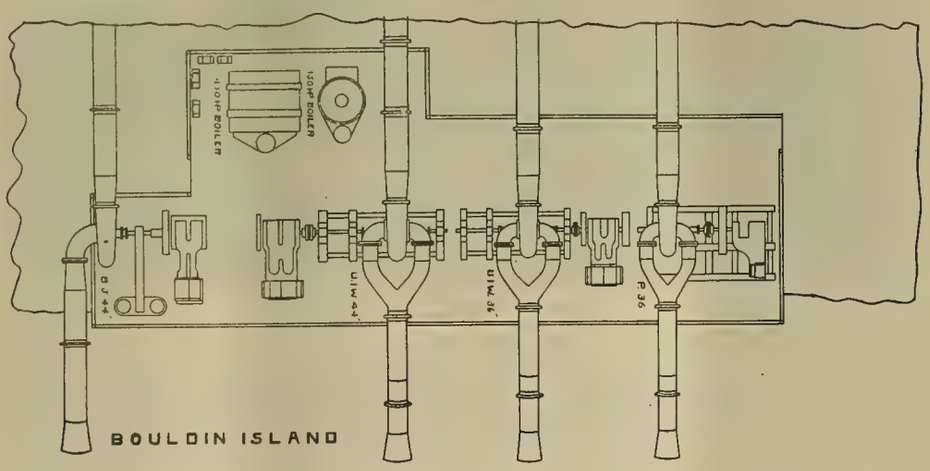
The plant consisted of the following units: The largest pump was furnished by the United Iron Works, having 44-inch suction and discharge openings, connected to 48 inch suction and discharge pipes, having a capacity of 60,000 gallons per minute when running at 230 revolutions per minute. This pump was direct connected to a 350 H. P. Ball cross compound engine on substantial steel sub-base, by means of a flexible link coupling; occupied a space of 28 feet long by 12 feet wide. The top of the pump was 13 feet above the floor and the floor line for all was 2 feet above the water line. The second pump was a 36-inch United Iron Works pump connected to 40-inch suction and discharge pipes, having a capacity of 35,000 gallons per minute when running 250 revolutions per minute. The same was direct connected to a 200 H. P. Ball cross compound engine on I-beam sub-base by means of a special solid coupling. This unit occupied a space of 20 feet by 10 feet; both of these pumps occupied more space than they otherwise would, because they had been prepared to be operated either belt driven, or direct connected, as desired. The third unit was a Byron Jackson Machine Works 44-inch pump connected to 48-inch suction and discharge pipes, having a rated capacity of 50,000 gallons per minute when running at 200 revolutions per minute; was direct connected on I-beam sub-base by solid coupling to a Jackson single valve cross compound condensing engine with jet condenser. The same occupied a space of 14 feet by 14 feet. The fourth unit was a Price 36-inch pump, having a rated capacity of 35,000 gallons per minute when running 210 revolutions per minute. This pump was direct connected upon timber sub-base by solid coupling to 200 H. P. Brownell automatic high speed engine. The space occupied was 14 feet by 12 feet in width.

Steam was supplied by a stationary plant of 550 H. P. and a river steamer (City of Stockton) having a rated capacity of 450 H. P. The stationary plant consisted of one 400 H. P. Scotch marine boiler 12 feet diameter, 13 feet long, having three fire tubes, each fitted with the latest improved oil burners, and one 150 H. P. vertical, 7-foot by 12-foot, boiler. The river steamer was moored to the wharf and steam carried ashore through 125 feet of 8-inch pipe. As the tide varied the water level 3 to 4 feet twice a day, it was necessary to have a flexible connection between steamer and shore line. This was accomplished by means of ball joints, as shown in cut. All boilers were fitted with oil burners. Oil was supplied by oil barge and temporary storage was made in one 10,000-gallon wooden tank and two auxiliary 5000 gallon galvanized iron tanks. Every known precaution was taken to insure safety in handling the oil and maintaining the fires.

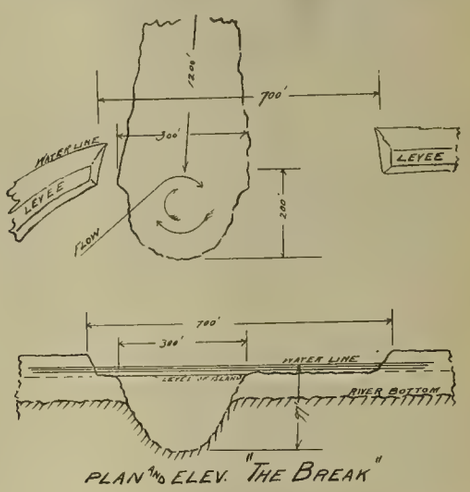
Each pump was primed by steam and no difficulty was encountered, even when water receded to a point 26 feet below the top of the pump The time required at first priming was about twelve minutes, which increased until it took over thirty-five minutes when the last of the water was being handled. No pump unit was run at full speed when all the pumps were in operation, for the pump and engine portion of the plant were in excess of the steam generated. The operation and performance were ideal, and all that could be expected of such a large plant, installed so quickly in face of the difficult conditions surrounding the same.

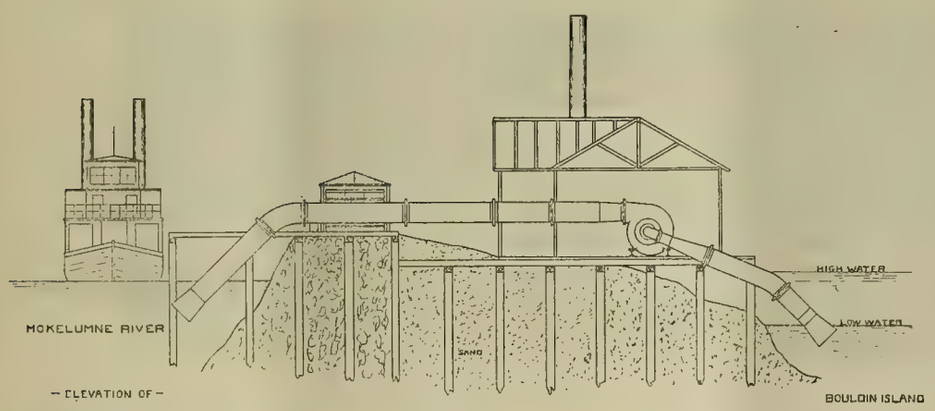
With all pumps in operation the capacity was about 165,000 gallons per minute—equivalent to 10,000,000 gallons per hour. During the time of pumping no less than 6 inches of rain fell on the island, which increased the duty to be performed about 1,200,000,000 gallons. Fortunately, this rainfall occurred during the earlier period of pumping, thereby saving much in head effect. The oil consumption ranged from 60 to 110 barrels per day of twenty-four hours, and 2500 barrels of oil was used in draining the island.

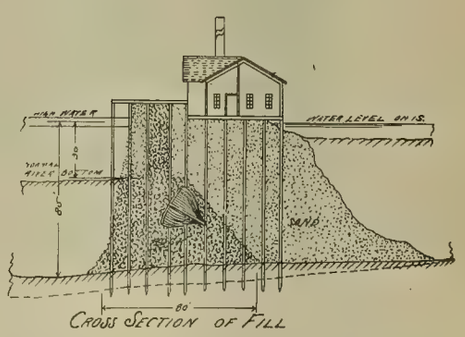
Pumping was begun December 8, 1904, before the plant was entirely completed. All pumps were in operation by January 10, 1905, and operated continuously for thirty days, after which time stops were made on first one pump and then another to lower the suction pipe. By February 15, 1905, the island was practically drained, although intermittent pumping was continued to July 1, 1905. Credit is due to Henry Voorman for foundations, to Walter M. Willet on problems of plant design and materials and to F. W. Langley, of the United Iron Works, on plant installation and operation. Upon these men fell the responsibility of the problems encountered, and to them belongs the credit of successfully performing a piece of work of larger magnitude and more serious import than the above words imply.



Plan of Pumping Plant.







Electric Mine Signals and Telephones.

Written for the MINING AND SCIENTIFIC PRESS by GEORGE E. WALSH.

The introduction of electricity in a mine for power or lighting purposes is usually followed in the course of time by equipments for telegraphing, telephoning or general mine signaling. The mines of Germany and the continent of Europe have developed more efficient systems of electrical communication than in this country, but indications are not lacking that engineers are steadily availing themselves of telegraphic signaling in the Far West where electricity is used in the mines. The harnessing of mountain streams for generating electric mine power is rapidly changing conditions in many of the Western mines and, with current supplied in abundance at a low cost, the work of extending the electrical equipment to all kinds of mechanical operation progresses rapidly. While few, if any, mines are operated throughout solely by electricity, there are many which are electrically equipped, and in some of them nearly every phase of mine work is performed.

In the continental mines lighting, signaling, hoisting, drifting, ventilation, hauling and tramming, and firing of shots are operated by electricity—and as a valuable and economical auxiliary the electric plant has few equals. In the matter of lighting and signaling, electricity has received more attention on the continent of Europe than for power purposes. In a good many mines where steam and compressed air still hold their own for operating machinery, electricity is employed for lighting and telegraphing. Where a small plant is employed for lighting purposes, the installation of a complete signaling system is not difficult or costly to operate. The tendency is thus to use both the telegraphic and telephonic methods of mine signaling.

The telegraphic systems which have been developed for mine uses vary somewhat, but in their final results they attain the same trustworthy end. Usually a transmitter and receiver are installed in each station. In many cases the telephone is used in connection with the telegraph. The voltmeter is arranged with a dial, around which a number of signals or orders are arranged. This receiver is plainly marked, and the signals easily read. The transmitter consists of a magneto machine, provided with a dial and corresponding signals or orders. When the operator transmits a message, he turns a crank on the machine until the handle reaches the signal on the dial. Immediately the voltmeter indicates the

transmission of the message and records the result. In a few mines a further precaution is obtained by a small electric bell, which is immediately thrown in circuit, and the strokes of this bell correspond to the number of the signals: The danger of mistakes appears almost entirely eliminated by this method, but where extreme precautions are demanded the operator must have his message repeated, so that he is sure that the receiver on the other end understands the communication.

At first thought it would appear as if this method might be slow and clumsy, but experience has demonstrated the contrary. The dial is very small and the needle a very fine one, so that the operator can actually send more messages in this way than any other. Repeating the messages furthermore places any mistake in transmitting orders upon the shoulders of the right person, who, realizing his responsibility, is more apt to exercise greater care. The ordinary telegraphic code is employed in parts of the mine where communication is important and frequent, but often only ordinary "sounders" are used for the signaling.

Where simple sounders are used bare wires are strung down the mine and through the different galleries. Nothing is simpler and easier than to equip every part of a mine with such a telegraphic system. With two bare wires running from the signal bell at the hauling engine through the galleries to the trams, the service permits ready adjustments to any conditions. An ordinary piece of metal of any kind completes the circuit for the transmission of signals at any point. The elasticity and portability of such a method of mine signaling particularly recommends itself to mines where the work of the day is shifting constantly from one point to another. Wherever the miners are working they are kept in close touch with the central operator and the managing office itself.

The introduction of the telephone in the mines is of more recent occurrence, but its service is rapidly becoming invaluable. The portable telephone outfit permits operators of any gallery to keep in direct communication with headquarters at every step. The safety and rapidity of signaling by this method proves of great economy in large mines where a large number of men are working. In the German mines, where telephonic communication has been established between the manager's office and the different gangs of workmen, the saving of time in transmitting orders has proved of vital importance in a number of instances. Dangers have been averted in this way, and the miners in more than one instance owe their lives to the underground telephones.

Special telephones have been manufactured for such underground use in Europe. Owing to the noise made in the mine by the cutting or drilling machinery, it is difficult sometimes to hear through the ordinary telephone. To obviate such difficulty loud-speaking telephone instruments are employed. They are also provided with movable receiver tubes, which can be adjusted to the ears to make certain of any messages transmitted. Both the receivers and transmitters are provided with rubber stops, which close them when not in use.

The installation of a telephone system with the different parts of a mine is of a simple nature, and owing to the fact that the wires can be easily strung along the sides or carried on a tram car, by means of an automatically working reel, the expense is not great. The telephone is kept in circuit with the various lines by means of a series of push buttons. The operator at headquarters can thus connect with any gallery when needed, and the foreman of any working gang can as easily call up central for orders. The use of the portable telephone outfit for mines gives an elasticity to this method of communication that cannot be surpassed.

Accidents in mines frequently happen through mistakes in signals. In most cases this is the result of temporarily forgetting the different signals, either in receiving or transmitting, but such mistakes could hardly happen where the orders are given by word of mouth through telephones. As the size and importance of a mine increases, the need of safer and more efficient signaling systems is felt—and in the end the best pays.

Handling Ore Cars.

Herewith is shown a 15 H. P. distillate locomotive, built by the Union Gas Engine Co., San Francisco, Cal., for the Yellow Aster Mining & Milling Co., Randsburg, Cal. The engine is a 15 H. P. double cylinder "Union" of the 1905 type; all parts are so arranged as to be easily accessible. It is fitted with a sensitive governor designed to allow fuel to be used only in proportion to the work performed. It has a speed controller by which the speed can be set at any desired rate and maintained without any further attention. The oil and water tanks are mounted on the rear. The pulling power of this locomotive is stated to be thirty tons gross load 6 miles per hour, on a level straight track, and with a variable speed that permits of slowing down on heavy grades or around curves. The total weight of the locomotive, with water, is 6200 pounds. The net weight of the engine only is 2085 pounds. The Yellow Aster Mining & Milling Co. have been using five "Union" hoists, one of which is of 130 H. P., for the past five years.

"Union" Distillate Locomotive.

"Union" Distillate Locomotive and Train Hauling Ore From the Yellow Aster Mine, Randsburg, Cal.

Compact Oxygen.

A new chemical for metallurgical and other industrial and sanitary purposes has been introduced by the Roessler & Hasslacher Chemical Co. of New York, which affords possibilities for supplying oxygen to charges of ore in the cyanide process. This new substance is called oxone, and comes in solid form. It is described by the manufacturers as follows:

A stone about 1 cubic inch in size, weighing two to three ounces, generating upon contact with water 130 times its volume on pure oxygen gas, is certainly of great value. This is oxone. Oxone is a compact oxygen compound made for the purpose of providing anybody with the means to produce instantaneously, free, chemically pure oxygen gas in a simple manner. As the generation of oxygen is at once obtained upon throwing a piece of oxone into water, and as the amount of gas produced can easily be regulated by varying the quantities of oxone, or controlling the water flow, it is obvious that by this means the important question of an abundant oxygen supply for general use has progressed considerably. Not only will all the users of the gas be benefited, but a number of new fields in hygiene and industry will be opened to that simple and reliable source of oxygen gas.

The way in which oxygen up to this date came on the market was in form of gas compressed in iron tubes or drums. The inconveniences in connection with this means are well known. The expenses of shipping, the clumsy way of handling these heavy containers, the trouble of reshipping for the sake of refilling same, the leakage due to high pressure, the danger in connection with it, and—last not least—the gas being never more than 90% pure; all these facts point to the necessity of adopting a better means to provide us with this most valuable gas of the predominating of all elements—oxygen. The claim is made that oxone produces oxygen gas instantaneously. A light weight and small volume for shipment yields a large amount of gas. It can be stored and used at any time, it is easy to handle, and is not explosive nor combustible. The only precaution to be taken is to protect it against moisture to prevent untimely decomposition. One pound of oxone furnishes fully 2 cubic feet or 57 to 60 liter of oxygen, or 100 grams generate 13,000 c.c.

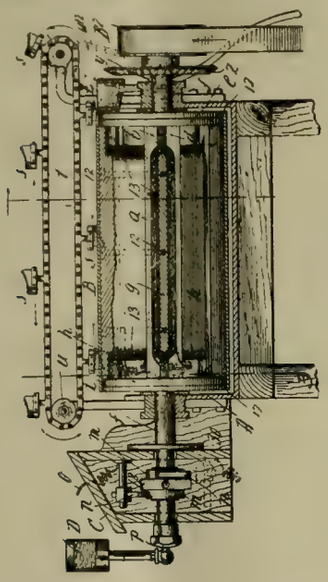
AS THE RESULT of a personal inquiry into the vexed question of the damage done to water courses and water supplies by dredging, the Victorian Minister for Mines is convinced, says the Town and Country Journal, that, with proper conditions as to the leases and the construction of modern types of dredgers, the beds of rivers can be dredged, not only without injury to the streams themselves, but with positive advantage to the rivers. In Victoria, during the last five years, gold to the value of £1,100,000 has been won by dredging and sluicing, in addition to which stream tin to the value of about £15,000 was obtained. The plants employed are valued at £250,000, and there has been about £400,000 of capital called up. In 1903 the industry kept 1310 miners in employment. The companies worked 240½ acres in that year, including the beds of streams that were turned over, and the yield averaged 2.35 grains per cubic yard, giving an average of £636 per acre. Last year £97,000 was paid in dividends by various companies, exclusive of the amounts paid to shareholders in small companies, of which the Mines Department has no record.

Mining and Metallurgical Patents.

PATENTS ISSUED JUNE 27, 1905.

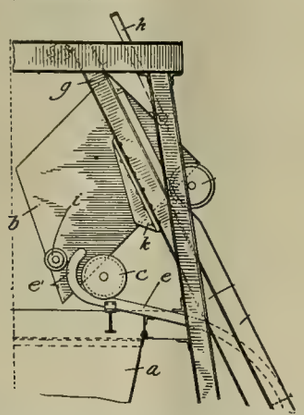
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MAGNETIC SEPARATOR.—No. 792,776; E. C. Kavanaugh, Holyoke, Mass.



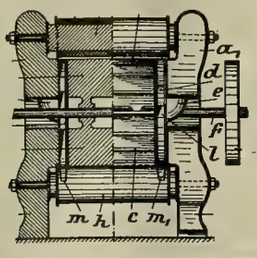
In magnetic separator, inclosed magnetic cylinder rotatably mounted in pulp receptacle, or conduit, having pole pieces and magnetic coils therein, and having hollow endwise-extending journal having at extremity stuffing box, combined with suitably elevated oil receptacle having depending conduit provided with horizontal limb entered within extremity of hollow journal through stuffing box thereat, and communicating with spaces within cylinder.

GUIDE FOR SKIP CARS OR THE LIKE.—No. 793,102; R. Schneider, Sharon, Pa.



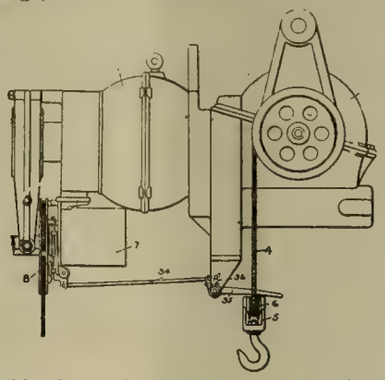
In combination with hopper of blast furnace or like, skip car having front and rear wheels and hoisting means for car, inclined track leading to top of hopper upon which wheels run, track portions curving inwardly at inner ends upon which forward wheels only run, when car reaches top of furnace, and having upwardly and rearwardly turned ends and other track portions on which rear wheels only run, and contact members on car for engaging upwardly turned ends when car is overhoisted.

ELECTRO-MAGNETIC ORE SEPARATOR.—No. 793,137; E. Langguth, Euskirchen, Germany.



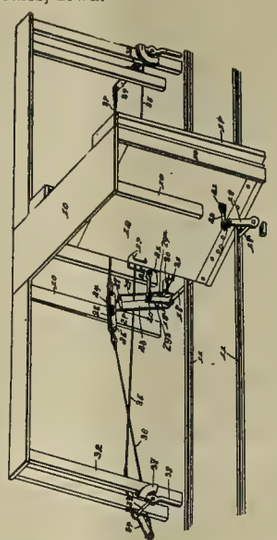
In magnetic separator, combination with primary pole piece, of rotary member provided with plurality of secondary pole pieces and arranged to rotate adjacent to and parallel with primary pole piece, part of path of rotary member being out of field of influence of primary pole piece, and casing of non-magnetic material between primary pole piece and rotary member.

ELECTRIC HOIST.—No. 793,626; P. J. Darlington, Glenridge, N. J.



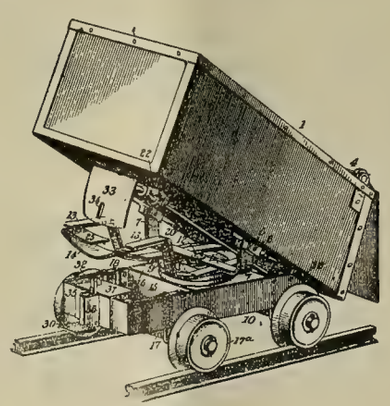
Combination with winding drum and pulley block to be operated thereby, of electric motor for operating drum, electric circuit including motor, controlling switch in circuit, operating member, means for locking member to movable contact carrying member of switch, means for returning contact carrying member to its "off" position when members are unlocked, and means controlled by pulley block for unlocking members and allowing switch to return to "off" position.

AUTOMATIC MINE DOOR.—No. 793,452; O. W. Lundholm, Des Moines, Iowa.



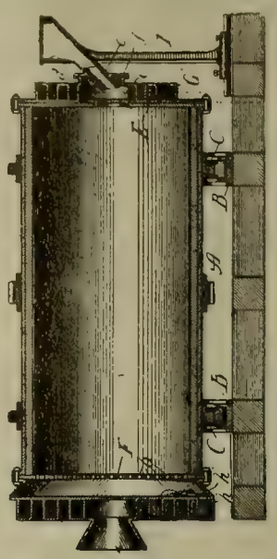
Combination of two door sections, in closed positions standing approximately at right angles to each other and means for pivotally supporting each of door sections at upper and lower ends at points between center and outer end, and stationary partitions arranged to engage outer ends of door sections when sections are in open positions.

DUMPING CAR.—No. 793,385; A. Mieden, Seattle, Wash.



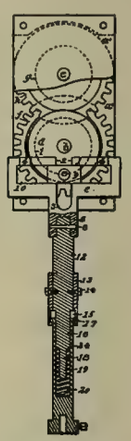
In device of class described, combination with dumping body having door, of plate or member mounted on door and beveled to form inclined and angularly disposed face, and shaft provided with V-shaped arm having inner portion disposed at obtuse angle to shaft, and outer portion arranged at inclination and presenting inclined face to door when in engagement with same, inclined face of catch co-operating with inclined and angularly disposed face of the plate or member.

PEBBLE MILL.—No. 792,778; W. A. Koneman, Chicago, Ill.



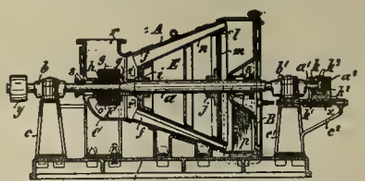
In pebble mill, combination of rotatably supported cylinder having feed opening in eccentric position in one end, central feed chamber on end with means for feeding thereto material to be ground in cylinder, spiral conduit on cylinder end extending from chamber to feed opening to discharge into latter, and centripetally acting discharging means for material on opposite end of cylinder.

HAND ROCK DRILL.—No. 793,319; C. F. Paul, Jr., Peekskill, N. Y.



In hand rock drill described drill spindle secured to operating yoke comprising main spindle with reduced ends to receive sleeve-drill holding spindle and spiral spring, sleeve-drill holding spindle with spring end of main spindle forming recess for spring, spring in recess, flange on sleeve end of drill-holding spindle inclosed within recess formed by reduced part of main spindle and recess in clamping sleeve.

APPARATUS FOR PURIFYING BLAST FURNACE GASES.—No. 793,544; W. Schwarz, Dortmund, Germany.



In apparatus for purifying blast furnace gases, combination with stationary casing, of rapidly rotating conical drum and dispersing member, both rotating within casing about common axis.

PROCESS OF TREATING THE METAL MIXTURES PRODUCED AS A BY-PRODUCT IN ELECTROLYTIC METAL REFINING.—No. 793,039; A. G. Betts, Troy, N. Y.

Process of treating anode slimes which consists in treatment with solution of ferric sulphate, and separating solution from insoluble material; dissolving copper in solution; electrolyzing solution with insoluble anodes for simultaneous production of ferric sulphate solution and deposition of copper; and in operation of extracting antimony from material undissolved by ferric sulphate solution, by treatment with solution containing hydrofluoric acid, and removing antimony therefrom by electrolysis with insoluble anode.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

F. H. Oliphant of the United States Geological Survey gives the following statement regarding the total quantity and value of crude petroleum produced in 1904:

State.	Quantity. Barrels	Value	Value per Barrel.
California	29,649,434	$ 8,265,434	$0.279
Colorado	501,763	578,035	1.152
Indiana	11,339,124	12,235,674	1.079
Indian Territory, Oklahoma Territory	1,366,748	5,447,622	0.969
Kansas	4,250,779		
Kentucky, Tennessee	998,284	984,938	0.9866
Louisiana (a)	2,941,419	1,068,605	0.3633
Michigan, Missouri	2,572	4,769	1.854
New York	938,234	1,526,976	1.6275
Ohio	18,876,031	23,730,515	1.257
Pennsylvania	11,300,792	18,507,103	1 6377
Texas	22,241,413	8,156,220	0.367
West Virginia	12,644,686	20,583,781	1.628
Wyoming	11,542	8 1.794	0:70
Totals	117.598,421	$101,170,466	.864

(a) In addition to this quantity 3,670,000 barrels were produced and unsold at close of 1904.

California, Utah and Virginia were the only States that produced manganese ore in 1904. The total production amounted to 3146 long tons, valued at $29,466, or $9.37 a ton. Of the total production, 3054 tons, or 97%, came from Virginia, 60 tons, or 2%, from California, and 32 tons, or 1%, from Utah. In addition to the true manganese ores, considerable quantities of manganiferous iron ore are obtained in Colorado, Arkansas and in the Lake Superior region. This amounted in 1904 to 383,246 long tons, which had a reported value at the mines of $691,677. Ore of this class carrying 28% of manganese and 10% to 14% iron was mined and used in the manufacture of pig iron, with 1% or over of manganese. The Colorado manganiferous iron ores are utilized primarily as flux by the precious metal smelters, the remainder being employed in the manufacture of spiegeleisen. In the Lake Superior region quantities of iron ore are mined which analyze from a fraction of 1% up to 20% of manganese. In mining silver ores in Colorado a considerable quantity of mineral is obtained which contains insufficient percentages of the precious metal to make it valuable on that account, but which is used as a flux by the smelters. In 1904 the production of manganiferous silver-iron ores in the United States amounted to 105,278 long tons, valued at $348,132. This is considerably less than the production of 1903, which amounted to 179,205 tons, worth $649,727. A by-product in the manufacture of zinc from ores mined in northern New Jersey, containing iron and manganese, is utilized in the production of spiegeleisen. In 1904, 68,189 long tons of this class of ore were obtained. The total quantity of manganese ore, manganiferous iron ore, argentiferous manganiferous ore and zinc residuum produced in the United States in 1904 amounted to 559,859 long tons, valued at $1,137,264.

ARIZONA.

Cochise County.

(Special Correspondence).—The Black Diamond Copper Co., whose mines and smelter are located near Pearce, in the Cochise mountains, has proved that its smelter has a capacity of 200 tons a day and that its ores are self-fluxing. A water plant has been put in. Its ¾-mile aerial tramway from the mouth of the tunnel to the smelter has proved efficient.

Pearce, July 2.

(Special Correspondence).—The Tombstone Con. Mines Co. are shipping regularly and expect to open up more of their mines. The new pump ordered will have a capacity of 2,500,000 gallons, which will increase the capacity of the pumping plant to 6,000,000 gallons a day. Work has been started remodeling the old 20-stamp Girard mill, which will be increased to a capacity of forty stamps. A concentrator will also be put up on the grounds, so that the ore can be concentrated and the waste removed and save considerable expense to the company in shipping ore.

Tombstone, July 1.

(Special Correspondence).—The Consolidated M. Co. has made a new strike on the Davis group in the Chirichuahua mountains, near Douglas. The ore is refractory, but the extraction problem has been solved in the arrangements to put in a concentrator of large capacity for testing the new ore.

Douglas, July 3.

It is reported that the Pittsburg & Hecla property at Bisbee has reverted to the original owners. Lands are the Gold Hill group in Solomon Springs district, 3½ miles southeast of Bisbee. Work for the present has been suspended.——The cyanide plant of the Fortuna mine, in the mountains south of Gila Bend, is being moved to Fairbanks. S. Anderson is superintending the moving of the plant.

Gila County.

The Arizona Commercial Copper Co. of Globe has made arrangements with the Old Dominion Co. whereby the fluxing ores of the former will be treated by the latter. A track will be laid from the Arizona Commercial to the Old Dominion. The excess supply of ore not sold to the Old Dominion will be sent to Douglas. The directors state that a reduction works, including a smelter for the handling of the ores, will be erected within a year. The ore now being sent to the Old Dominion smelter is of a quality that has previously been shipped into Globe from a distance. It is working excellently in the furnaces of the Old Dominion and will simplify another one of the problems of the company. Besides its workings on the Black Hawk property, the company has a 600-foot shaft on the Copper Hill property.

Graham County.

(Special Correspondence).—The superintendent of the Standard mines, near Metcalf, reports that the mine is doing well. A 20-inch streak of glance is being developed in the San Jose and shipments will be made this month, the first shipments from the San Jose since it was acquired by the Consolidated Co. At the Copper Center claims the main shaft is down 160 feet and three levels are being run.

Clifton, July 3.

It is reported that the Ash Peak mines, near Duncan, will begin operations under the direction of T. Larkin.

Maricopa County.

(Special Correspondence).—J. H. Strite has charge of building the mill near Wickenburg for the White G. M. Co. Twenty stamps are being put in, with provision for twenty more; the cyanide plant can handle tailings from a 40-stamp mill.

Wickenburg, July 3.

(Special Correspondence).—C. D. Pickering, superintendent of the Yucca Cyanide M. & M. Co. at Cedar, reports that work has been stopped on the shaft of the San Francisco mines on account of a larger flow of water than the pump could handle, but that as soon as the new pump is received work would be resumed. The shaft is down 570 feet and is in good ore. The mill is crushing twenty-five tons of ore daily and making a product of lead, silver and gold.

Kingman, July 3.

Superintendent G. Hamlin of the Relief G. M. Co.'s properties at Relief, 23 miles northwest of Phœnix, states that he is operating 500 feet west of the main shaft and is down 40 feet in a winze that he is running to the water level. Water has been secured by sinking a 500-foot shaft on the vein.

The Oro Grande mill at Wickenburg is operating ten stamps on ore taken out in development work.——It is reported that work has been resumed on the Goddard mine, near Wickenburg.

Mohave County.

The Monarch G. M. Co.'s property is being worked, with E. Hilty of Kingman as general manager.——The German-American mill, near Vivian, is working to its full capacity, and is said to be making a good saving of values. The mill is of ten stamps and will handle thirty-five tons of ore daily. O. F. Kuencer is in charge.——The 10-stamp mill of the Blue Ridge M. Co. is running full capacity. A cyanide plant for the handling of the tailings is contemplated.——T. Ewing is working four properties in the San Francisco district, within a radius of 6 miles of Vivian—the Vivian, Virgin & Victor, Hardy and Homestake.——W. A. Mensch of Kingman is putting hoisting machinery on the Enterprise mine.——T. R. Garnier, regarding the St. Louis mine at Cerbat, reports that the tunnel is in 375 feet on the vein.——The Treasure Hill mines are being unwatered to the 200-foot level, when crosscutting to the veins will be commenced. J. D. Jordan has charge.——E. M. Carson of San Francisco, Cal., proposes to build a 100-ton smelter at McConnico.

The Chloride G. M. Co. is planning putting in a second compressor and sinking the working shaft to a depth of 800 feet. Development of the Samoa group, near Chloride, has blocked out a large quantity of shipping ore.——The Pilgrim group, 12 miles west of Chloride, is being worked under bond by the Commonwealth M. Co.——The Azalia group, near the Pilgrim, has been bonded by the Commonwealth Co., and is being developed.

Pima County.

(Special Correspondence).—The double-compartment shaft at the Weeden mine at Pittsburg will be sunk 600 feet. The smelter is turning out ten tons of 75% copper matte daily. Each shaft is 5 feet in the clear and the work is proceeding at the rate of 3 feet per day.

Mellen, July 3.

Pinal County.

(Special Correspondence).—It is reported that Superintendent C. Brown of the Arizona-Hancock Co. has uncovered rich ore in the property, 1½ mile south of Superior.

Superior, July 3.

Yavapai County.

General Manager Campbell of the Richenbar M. Co. at Richenbar intends putting in a cyanide plant, enlarging the capacity of the mill, and putting in a new hoisting plant.——L. Walloth and D. Sinclair of Yarnell have shipped a carload of mica from the Monte Cristo mine, in the Peeples valley.——E. Block of Prescott has sent out a whim to his copper claims, 7 miles west of Jerome Junction, and has given J. F. Wright and P. Jasperson a contract to sink the main shaft, now 75 feet deep, 100 feet deeper.

C. K. Tibbets has bonded R. Lyon's claims, near Cherry, and is putting up a hoist and steam stamp mill capable of treating ten tons of ore a day.

CALIFORNIA.

During 1904 California produced, according to the U. S. Geological Survey reports, 29,649.434 barrels of crude petroleum, valued at $8,265,434, an average of $0.279 per barrel. In 1902 the production was 13,984,268 barrels, valued at $4,873,617, or $0.348 per barrel, and in 1903 the production was 24,382,472 barrels, valued at $7,399,349, or $0.303 per barrel. California now produces the greatest number of barrels of oil in the United States, Texas coming second, with 22,241,413 barrels, and Ohio third, with 18,876.631 barrels. The average value per barrel, $0.279, is lower than that obtained in any other State, Louisiana coming next, with $0.3633.

Amador County.

At the Climax mine, near Pine Grove, it is reported that they intend to put up a 20-stamp mill before winter.——Parties who have a bond on Dry creek, near Ione, have had a Keystone driller at work trying to determine its value for dredging purposes. They have found a deep soil ranging from 5 to 15 feet, and gravel from 5 to 25 feet thick.

Butte County.

H. Zilmer, manager of the Wyandotte M. Co., reports a rich strike in the mine near Wyandotte.

Calaveras County.

Prospecting the lands of the Calaveras river bottom at Petersburg, near Valley Spring, is being done, with a view to working the gravel by dredger.

Contra Costa County.

It is reported that the coal mines at Summerville will soon be in operation, after many months idleness. The Summerville mines closed down on account of the poor demand for coal, the river steamers and many manufacturing plants having changed their furnaces to oil burners. A new superintendent for the mine has been engaged and the work of retimbering has begun.

Del Norte County.

Superintendent Frank Rood, of the Big Bar mine, at the mouth of Slate creek, on the Klamath river, reports the mining season along the river at an end. It has been a very short season for the placer miners, on account of the light snowfall on the high mountains, but it proved to be a good one.

Inyo County.

It is reported that John Hays Hammond, acting with the Guggenheims, has purchased the Piper ranch, 23 miles from Tule canyon, and it is proposed to introduce gold dredging in Cottonwood creek.

Mariposa County.

The North Star silver mine at Bootjack, owned by D. McNally, is under bond to H. Dibble of San Francisco and F. D. Cochrane of Boston, and will be pumped out and sampled, and if found to be as represented, active development will be begun. A. C. Morrison of San Francisco is in charge.

Merced County.

The land north of the Merced river, between Snelling and the falls, has been bonded, and drilling machines will start prospecting the land as to its availability for dredging.

Nevada County.

The Pennsylvania mill, near Grass Valley, is being overhauled.——A. Richards of Washington, foreman of the Sixteen-to-One mine, reports that the 20-stamp mill is kept constantly running. The mine is worked through a tunnel 600 feet in length, and seventeen miners and eight surface hands are employed.——It is stated that A. H. Godbe of Salt Lake City will build a cyanide plant at the Excelsior mine, in Meadow Lake district.

As a result of a burst in the Mountaineer mine's power pipe line, near Nevada City, the mine was temporarily closed down.——The Gluyas shaft at the Home mine, near Grass Valley, is to be pumped out and work resumed. The Home at present is running thirty stamps.

Placer County.

The machinery installed at the Bellevue mine, near Auburn, is in place and work has been started.——At the Smith Point mine a drift is being run on the 200-foot level.——The Tadpole mine, 5 miles above Westville, is reported to be working four men, and ore will be crushed at the Alameda mill at Black Canyon until the mine is thoroughly tested and prospected.

Riverside County.

G. L. Leonard has charge of the work of the United States Tin Co. in reconcentrating tailings from the Temescal tin mines. At the same time the tin-bearing and copper-bearing deposits on the property will be developed.

Santa Barbara County.

The Standard Oil Co. announces a schedule on oil from Santa Barbara fields as follows: Oil of 24 to but exclusive of 25 gravity, 22½ cents; 25 to but exclusive of 26 gravity, 27½ cents; 26 to but exclusive of 27 gravity, 30 cents; 27 gravity or better, 35 cents. The prices quoted above are about 5 cents less for each grade than those proclaimed on January 1, which were in turn a cut of a larger figure from those prevailing prior to that date. Within the last year the quotation for Santa Maria oil has fallen nearly 100%, although development has only began, and little or no oil has been sold. The Union is, of course, independent of the Standard, and has its own pipe line, the Western Union and the Pinal having long-time contracts with the Standard.

Shasta County.

The Holt & Gregg Co. will build a rail tramway from its limerock quarries between Big and Little Backbone creeks, 2 miles west of Kennett, to carry rock from the quarry to the company's lime kilns at Kennett and to the main line of the Southern Pacific Co. at that point.

It is reported that the Balaklala copper mines, near Kennett, have been sold to the Western Exploration Co. for $2,000,000.——J. James and four other miners claim to have sunk 100 feet, from the No. 5 level to the No. 6 level in the Rising Star mine, near De Lamar, in thirty-seven days.

Sierra County.

Work is to be resumed at the Mabel Mertz mine at Forest City by the Forest City M. Co.

Sonoma County.

Rich cinnabar ore is being taken from the Culver-Baer quicksilver mine near Healdsburg.——The recent strike in the Sonoma mine has encouraged the owners of properties all along the quicksilver belt to action.——The Socrates Co. are working on the construction of their new furnace.

Tulare County.

Superintendent F. Marshal of the Ada Jewel mine at Fountain Springs, near White River, has started the new cyanide plant on ore on the dump.——In the upper Deer Creek district J. L. Showers is opening up the Royal Flush, 8 miles from Hot Springs.

Tuolumne County.

The Clio mine, near Jacksonville, is running steadily. The shaft is down 150 feet and is being sunk deeper. A slate vein on the hanging wall showed such values that the mill was started.——The Harvard mine at Whiskey Hill, near Sonora, is soon to resume operation.——Work has been started at the Mount Lily, near Columbia, with C. Grimm as superintendent.——Prospecting work has begun at the Water Lily gravel claim on the Stanislaus, near Sonora. It is owned by C. Durgan, Lyon Bros. et al.

COLORADO.

Boulder County.

The Inter-Ocean M. Co. will put in a complete roasting and cyanide plant near the Inter-Ocean mine at Sunshine.

Custer County.

The Bassick G. M. Co., which operates the Bassick mine at Querida, contemplate building another mill to treat the ores from the mine.

Clear Creek County

F. A. Maxwell of Georgetown has a three years lease and bond on the Colorado Central and Allundi properties on Leavenworth mountain and will develop them. ——Development has been retarded on the Waldorf properties, near Georgetown, because of putting in two new compressors. The erection of a mill to treat the low grade ores will be the next improvement.——An air compressor and an 80 H. P. boiler has been put in at the mouth of the Hoosac tunnel near Fall River.

Manager J. Broad of the La Plata group, on Democrat mountain, near Georgetown, has started a lower crosscut to catch the ore shoot of the La Plata vein. The main tunnel is in 1200 feet.——The Silver Glance, near Georgetown, is being developed by Clark & Co.——Work has been commenced on the Centennial property, on Leavenworth mountain, at Georgetown, under the management of D. Kennedy.——Work on the Pacific tunnel holdings is being done by the Pay Rock Extension M., M., T. & D. Co., of which J. H. Robeson is manager. The tunnel is in nearly 800 feet. The mill machinery is being overhauled.——Upon the return of J. J. White, a new contract is to be awarded for driving the Prudential tunnel, which is destined to open a lateral from Georgetown to Silver Plume, thus furnishing an outlet for the ores of Republican mountain. The bore has been driven 700 feet, and it is expected that within an additional 100 feet the Magenta-Turner vein will be cut. A power plant and heavy machinery are to be put in at the mouth of the tunnel.——A vein has been cut in the Blue Bird tunnel, owned and operated by W. Hunt of Georgetown and N. Frohm of Denver. This group consists of the Blue Bird, Jay Bird, Black Bird and Snow Bird and is in the gulch between Republican and Democrat mountains. The tunnel is in 800 feet.

Manager A. B. Montgomery has made arrangements for increased development work in the property of the Red Oak Co., on Democrat mountain, near Georgetown. ——The Democrat Mountain M. Co., operating the Edgar, Junction, Fred Rogers and Government lodes, under the management of J. Smith, has started work on the 300-foot raise from the Bonanza tunnel level. With this work completed, twenty-eight drifts will be started, and the pocket of ore recently opened through the shaft workings of the Edgar can then be taken out cheaply. ——On the West Griffith, recently purchased by the Independent M. Co., ten men are sinking the winze at the 1100-foot station of the Griffith tunnel. This work will make a connection with the East Griffith property, owned by W. D. Hoover of Denver. Manager J. Larson states that a wire tram will be built from the portals of both the Sonora and Griffith tunnels to the railroad tracks.——At the Mineral Chief of the Linn Con. M. Co. of Georgetown operations are being carried on through the Moline tunnel. Manager W. C. Hood expects to start regular shipments soon.——In the working of the East Argentine M., M., D. & T. Co., Manager M. Sidney is employing twenty men and working three shifts. The claims are on Pendleton mountain and seven tunnels are being driven. The Sidney tunnel is being driven to cut the Stevens mine at a depth of 1600 feet below the 14th level. It will also cut all properties along the line of the Wilcox tunnel, as well as the Santiago. It is the deepest tunnel proposition in upper Clear Creek.

Chaffee County.

The Boston-Colorado Copper Co. are developing the Evening Star copper claims, 9 miles southwest of Salida. It is the intention of the management to put in a concentrator of suitable capacity to suit the low-grade body.

Gilpin County.

A whim has been put on the Silver mine near Moon gulch, which has been leased by W. H. Knowles of Denver and W. G. Smith. The shaft is down 150 feet, and is being pumped out under charge of E. J. Stephenson. ——It is reported that machinery is to be put on the Jo He tunnel property of the Alice E. M. Co., on Buckeye mountain, in the Phœnix district.——The Star of Gilpin M. & P. Co. has leased and bonded the Victoria claims in Lump gulch of the Central district, and active operations are under way. The Victoria shaft is down 150 feet, and is being unwatered for the purpose of sinking it another lift of 75 feet. This mill is equipped with 15 stamps. The company has also started a new shaft, 400 feet south of the main shaft, for prospecting purposes, and the company will also continue the 40-foot shaft on the Tiger, a parallel vein.——Sinking operations at the Happy Hollow claims, between Rollinsville and Gambell gulch, are under the superintendency of G. E. Churchill. Machinery for deeper workings is to be put in later.—— It is reported that work is to be resumed on the John L. mines, at the head of Virginia canyon, in the Russell Gulch district. The property is owned by E. W. Williams of Denver.——Sinking at the After Supper mine of the Banzai M. Co. at Black Hawk is down 340 feet. The shaft will be carried on down to the 365-foot point, from where they will extend levels both ways.

Grand County.

J. A. Burns has struck good ore in the Bowen & Campbell mining district, 12 miles northwest of Grand lake, in the Rabbit Ear range.

Gunnison County.

Near White Pine, on upper Tomichi creek, the Tomichi valley smelter is running full blast, putting through sixty tons per day of slag from the dump, which carries 7% lead, besides silver and gold values. Galena-lead carbonate ores are purchased from the North Star and May Mazeppa mines. Leescamp & Ferguson have charge of the work.——On the May Mazeppa and North Star, A. Woodworth and T. Allen are shipping ore from development work and J. B. Turner says he has 20 feet of galena-lead carbonate in his Dividend shaft workings of the North Star.——The properties of the Comstock G. & S. M. Co., near White Pine, are equipped with a compressor plant and surface improvements. A new concentrating and electrical ore separating plant will be put in.

The Grand Prize mine, near Pitkin, is being unwatered and work will be resumed taking out ore.——J. Nelson has secured a lease on the Teller and Chief, near Pitkin, and has begun work.——A good strike has been made on the Granite Mountain group, in Jones gulch, near Pitkin.——C. Oliver and others have leased the Fairview and Cleopatra, north of Pitkin. Work will be driven from the Cleopatra tunnel, which is in 1600 feet.

H. C. Clark of the Gregor K. mines, in Paradise basin, near Crested Butte, will start work.——G. Russ has started work upon the Washington mine near Irwin, and after clearing the shaft of water expects to sink deeper. —— Operations have been resumed at the Augusta mine near Crested Butte.

The Lanyon Zinc Co is meeting with success in operating the Napoleon and Edna Dranie properties on Gold hill, in eastern Gunnison county. The wagon road to Quartz, on the Colorado & Southern, has been put in good condition, and several ore teams will soon be busy hauling to this point for shipment to the company's works. A large force is employed at the mine, and the Lanyon Zinc Co. expects to soon commence shipping 30 tons per day.——The Tontine lode, in the Elk Mountain district, owned by J. Fleischer of Denver, is to be developed.

Hinsdale County.

Development work has been started on the properties of the Handies Peak G. M. Co., near Lake City, by Manager Corwin.——W. G. Pitts, secretary and superintendent of the Pittsburg Metals M. & M. Co., operating the Wyoming mine on Engineer mountain, near Lake City, has commenced new work, as the tunnel has been cleaned and retimbered.

Lake County.

(Special Correspondence).—The output for Leadville during June amounted to 72,000 tons. Up to date this camp, in its 27 years of life, has produced $316,000,000 worth of mineral.

Leadville, July 3.

The new work that was mapped out for the Big Evans section is now being carried out, and very few properties in that section are idle near Leadville. The most extensive work is being carried on at the New Monarch group, including the New Monarch, Winnie and Cleveland. The Winnie is shipping 150 tons daily. The Cleveland is shipping 400 tons monthly of oxides and sulphides, and the New Monarch is sending out 50 tons daily. Shipments are regulated by the demand from the smelter at Salida. The east shaft of the New Monarch, which is down 950 feet, is being cleaned out and will be sunk deeper to get under the main ore shoot, and when this is completed shipments from the property will be increased. A tunnel has been driven into the Cleveland, and all ore from the property now finds its way to the cars by this outlet. It has materially reduced the cost of mining, as hoisting is done away with.——Sinking is going on at the Silent Friend, and at the Little Ella ore is being shipped regularly.——The Resurrection is pumping water from No. 2 shaft to relieve the pressure at No. 1. That property is shipping about 100 tons daily.——The Gold Basin, near Leadville, has resumed work and the lessees are hunting for the main ore shoot. ——The Brattleboro is shipping steadily from ore that comes from the lower drifts.——By the middle of July the Yak mill will be turning out 250 tons of concentrates daily.

A good body of carbonate ore is being developed on the Bessie Wilgus, on Rock hill, Leadville, under the direction of R. B. Estey.——H. Collins and associates are sinking a shaft on the Oscar placer, part of the Revenue ground, Leadville.——The Center M. Co. is sinking a shaft on Rock hill, Leadville, under the management of C. E. Majors.——The Ben Burb shaft on Rock hill, Leadville, is being sunk by J. Weir.

The copper vein recently opened in the St. Julia claim, Lake Park creek, holds out as development work proceeds.——Work has been resumed on the Golden Jim and Hiawatha claims in Big Frying Pan district. The claims are worked through tunnels, both being in 70 feet.

On Dyer mountain, at the head of Iowa gulch, near Leadville, low-grade ore has been located on the Greater New York, and a tunnel is being driven by Holden & Greenwalt to tap it.——Experimental work is being done at the Yak mill and a few changes will be made before the mill starts on its steady run.

San Juan County.

On the Animas river, above Eureka, the Astor M. Co. have cut their vein at a depth of 1200 feet with a 1523-foot crosscut tunnel upon which they are drifting with machine drills. An electric plant is being put in near the tunnel mouth. It is to be run with water from the Animas river. A mill building intended to cover a 100-ton concentrating plant is being put up, but the concentrators will not be put in until further development work has been done. E. C. Condit has charge of work. ——The Silver Wing, near Eureka, is being opened up by the Eureka Exploration Co., under the direction of P. Molan.

A rich strike has been reported from the Mayflower mine in Arrastra basin, near Silverton.

Summit County.

Widmar & Dean, lessees of the Silver King property on Nigger hill, near Breckenridge, have started a drift from near the bottom of the Sprague shaft to cut their new ore shoot. The surface water still interferes with the active operation of a number of mines on Nigger hill, but is gradually subsiding.——The Buckeye M. & M. Co., operating the Lucky mine and the Reviere M. & M. Co. property on Mineral hill, has cleared the long tunnel and has it in good condition to work through. Superintendent G. E. Moon is opening up new bodies of lead-silver ore from the levels of the shaft. In autumn, when sufficient ore is blocked out, the company's mill will be started up.——The Old Union property, near Breckenridge, is doing development work. Some heavy ground has been encountered in driving the big tunnel, and 10x10-inch timbers are being used as posts and caps. Superintendent G. C. Smith is satisfied that a portion of the sulphide contact of the Breckenridge gold belt underlies Mineral hill.

The Harrison mine, near Montezuma, has started up. ——C. S. Young is operating the Sarsfield mine, on Collier mountain, near Montezuma.——W. Young, operating the Santa Fe with four men, is making air connections.——Superintendent H. C. Crover of the Bear Mountain M. & M. Co. is building an ore house at the New York tunnel, on Collier mountain, near Montezuma.

The Breckenridge Bulletin reports that the Mary Verna and North American company's properties are having development work pushed ahead under Manager McAlister.——Work on the new Laurium mill is progressing satisfactorily.——The compressor plant at the King Solomon is complete and the rock drills are doing good work.——Mr. Keables has men working on the Masontown M. & M. Co.'s property, paying particular attention to the mill which is being finished so that milling and cyaniding operations can be instituted soon.——W. P. Condon and E. W. Shrock, who have a lease on the Morning Star mine on Mount Baldy and are operating same with a small force of men, are taking out an excellent quality of silver-lead ore carrying gold values and expect to make a carload shipment to the local sampler some time next week.——The Abundance M. & M. Co. is employing twelve men on its mine. The shaft is down 150 feet, at which level two crosscuts are being run. The S. crosscut is in 40 feet and shows up a large body of mineralized rock. A drift is being run west from this on a vein of zinc-lead ore carrying gold and silver values. The northeast crosscut is in 80 feet. J. G. Goodier has ordered a new hoisting engine.

Teller County.

The Cripple Creek output for June amounted to $1,-725,200, with a total tonnage of 58,500. The output remains practically stable, although June, with one less working day, is nearly $131,000 short of the production in May:

Mills—	Tons.	Average.	Gross.
U. S. S. & R. Co.	20,400	$ 8 00	$616,000
Smelters	9,000	65 00	595,000
Portland	7,500	28 00	210,000
Economic	7,500	28 00	154,000
Wild Horse	2,160	6 00	12,960
Anaconda	2,100	5 00	15,500
Dorcas	3,300	32 50	107 2 0
Santa Rita	480	6 00	2,880
Michorado	460	3 50	1,610
Others	6,000	2 50	15,000
Totals	58,500		$1,730 200

Exploration on Grouse mountain at the Sprague group has been resumed by H. M. Sprague.——The 600-foot shaft of the Christmas mine, on Bull hill, Cripple Creek, is to be deepened an additional 300 feet. The lessees are breaking ore in the third, fifth and sixth levels.——P. S. Penn, leasing the Red Spruce Co.'s property on Gold hill, Cripple Creek, is pushing operations in the bottom level at a depth of 360 feet.——J. J. Winter and associate have struck good ore at a depth of 90 feet on block 24 of the Anaconda, on Bull hill, Cripple Creek.——The King & Craig cyanide mill has started after a month's shut-down for repairs.——C. Harrison intends to put in a steam hoist at a shaft on the two upper blocks of the Pride of Cripple Creek.

The C. O. D. mine, in Poverty gulch, Cripple Creek, is furnishing ore from the tenth level at a depth of 800 feet upward.——The Milwaukee Mutual Co., leasing through the main shaft of the Gold Dollar Con. property, on Beacon hill, Cripple Creek, expects to put in a larger plant of machinery to increase their output.—— Good ore has been struck in the T. Merrit claim of the Arno Co., situated on Womack hill, Cripple Creek. This is the fourth discovery that has been made by O. D. Fogleman, lessee, within two months.——A lease on the Annie C. claim of Copper mountain, Cripple Creek, has been obtained by A. Watson and brother, who will begin work in a 200-foot shaft which they propose to retimber. ——The shaft on Cleverdon's lease on the Vindicator, at Cripple Creek, has been sunk 50 feet deeper to the 250-foot level and crosscutting commenced. ——J. Freshman, operating the Pharmacist property, Cripple Creek, and working through the Finch shaft of the Acacia Co., has put in a motor-driven compressor capable of running several drills.——On the Empire State a new hoist has been put in by Crowder and associates and a large compressor has been ordered.——The Gold Sovereign Co., at Cripple Creek, has completed the installation of a hoist in the bottom level.——Troutfetter and associates, on the Shurtloff No. 2 property, have put in machinery for sinking 100 feet and then driving over to the ore body.——H. E. Chamberlain, who is operating under lease a block of the Midget mine, Cripple Creek, is putting in a washing machine.——Shipments are leaving the La Bella mine, of Bull hill, Cripple Creek, which is being operated under the direction of Superintendent W. Wilson. The La Bella is part of the Golden Cycle property.

IDAHO.

Idaho County.

The Crooked River M. & M. Co.'s mill at Orogrande is milling 300 tons daily, and expect to increase their milling capacity. It is reported that they are mining and milling their ore for less than $1 per ton, and the ore is being mined and delivered to the mill for 15 cents per ton.——W. C. Brower has charge of work on the Umatilla, at Orogrande.

Nez Perces County.

H. Fair reports of the Pittsburg - Idaho M. Co., on the Clearwater river between Greer and Kamiah, that Laverty Bros. have financed their company and will work this summer, planning to put in air drills and other necessary machinery.

Shoshone County.

The Cedar Creek M. & D. Co. has been formed at Wallace by T. N. Barnard, E. J. Hunter, John Weir, J. H. Jackson and J. L. Dunn, to take over the St. John, Cedar Creek, Palace, Thomas, Sunnyside, Laura and Grace claims in the Summit mining district.

It is reported that a dredger is to be put on Snake creek, 15 miles from Pierce. The ground on Orofino creek, near Pierce, upon which M. H. Hare of Wallace has a bond, is being prospected to determine its value. ——The Pawhattan M. Co. will resume development work on the mine on Big creek.

MICHIGAN.

Houghton County.

The Quincy expects that connections will be made between the Mesnard or No. 8 shaft, north of the Franklin mine, and the northerly drifts from the main Quincy property in July. The shaft is down 3354 feet at the 24th level. The distance between the levels in the Mesnard shaft does not correspond with that in the main Quincy mine, the former being 125 feet apart, while the latter in the upper levels are 60 feet. Therefore, the workings with which the Mesnard shaft will connect a short distance below the 24th level of that shaft have been raised for 100 feet above the 45th level of the old mine, which is the first level passing beneath the Franklin corner. Probably within three months after the connection is made between the Mesnard shaft and the lower Quincy workings the permanent hoisting engine for the Mesnard will be in service. It is to be of the standard double conical-drum duplex-cylinder type. The cylinder will be 32 inches in diameter and the stroke will be 72 inches. The minimum diameter of the drum at each end will be 12½ feet, and the maximum diameter in the centre will be 18¾ feet. It will have a capacity of hoisting from a depth of 5000 feet. The Quincy is shipping from its Mesnard or No. 8 shaft 10,000 tons of rock per month.

MONTANA.

Fergus County.

Superintendent H. H. Lang of the Kendall mine, at Kendall, says that the company is employing 125 men, and satisfactory progress is being made in sinking the new compartment shaft in the new ground, where ore bodies were located last year by means of the diamond drills. The shaft is being sunk below the 400-foot level, and will be pushed to the 1200 foot. The development of the old workings is continuing as usual. The 150 H. P. electric hoist is in place. A 7-drill compressor has been put in. A pumping station has been cut in the 400-foot level, for the pumps. The shaft is in ore, and drifting will commence shortly, but not much ore will be raised from this ground until the shaft is completed down to the 1200 level.——Superintendent H. H. Lang of the Kendall mine; C. D. Allen, foreman, and W. C. Waldorff of Helena, have sold a half interest in the 1900 mine to A. S. Wright, and a company will be formed to develop the property.——The Moccasin Mountain Co., of Kendall, has purchased from C. M. Goodell a claim adjoining the company's property.

Granite County.

Manager L. U. Loomis, of the Gold Reef M. Co., has resumed work on the 10-stamp mill to treat the ores produced from the company's mines, at Gold Reef, on South Boulder creek, near Philipsburg.

Jefferson County.

G. Benjamin has leased the Black Diamond copper mine, north of Elkhorn, to A. A. Rend, M. Little and J. Crowthers of Butte, and the men have commenced work.

Silver Bow County.

(Special Correspondence).—B. B. Thayer, assistant to President H. H. Rogers of the Amalgamated Copper Co., has completed an exhaustive inspection of the company's mines and says the ore on the lower levels shows no signs of diminution. The shaft of the Anaconda has reached a depth of 2400 feet.——The North Butte Copper Co. has made a contract with the Washoe Copper Co. for the treatment of its ores by the latter for a long term. The output of the North Butte for June was 1,450,000 pounds of copper, being equal to the output of the United Copper mines.——The output of the Washoe smelter for June was 12,540,000 pounds of copper, and that of the Boston & Montana smelter at Great Falls 4,750,000.

Butte, July 3.

The County Assessor has increased the assessment on the machinery and supplies of the Amalgamated Copper Co. in Silver Bow county $1,013,560. The returns of valuation as made by the various companies were increased that amount, it being claimed by the assessor that the returns made were too low. The total returns upon mining machinery and supplies amounted to $403,790, and the valuations placed by the assessor amounted to $1,617,350, making an increase of $1,013,560.

Preparations for development work by the Reins C. Co. is progressing at the Combination mine in Meaderville. The large station at the 800-foot level has been completed and made ready for putting in a second big pump, which will be a duplicate of the one now in operation on that level. Excavation for a cement tank for water storage purposes has been begun, and as soon as the new pump arrives and is installed the company will be able to handle 1200 gallons of water per minute. When the new engine arrives and is put in place, sinking from the 800-foot level will begin. A foundation is being prepared for one of the old engines, so that operations in the shaft will not have to cease while the new engine is being installed.

NEVADA.

Humboldt County.

(Special Correspondence).—At Jackson creek, 50 miles north from Humboldt House and 60 miles west from Winnemucca, Darling & Malley are working the Nelson group.——Murray Bros. are working a group near Jackson creek.——T. Fox, working on the North Star group at Jackson creek, has struck a ledge 5 feet wide.——H. Bender is working claims on Deer creek.

Humboldt House, July 3.

The opal claims of the late G. W. Ladd, near Lovelock, are to be opened on a large scale. Many opals of rare flash and brilliancy have been taken from them since the find was made. The estate is in the hands of W. H. A. Pike, who will sink a 50-foot shaft and work the claim.

Lander County.

The Austin M. Co. has sold its holdings in Austin to the Austin Hanapah M. Co., who will commence work. C. B. McCornick of Salt Lake City, B. F. Moffit and J. M. Ford of Chicago are interested. A working capital of $500,000 has been placed in the treasury. Manager Edwards says work will be commenced on the Clifton tunnel, Union mine and the McHardy mine in Marshall canyon and at Yankee Blade.

Lincoln County.

The Nevada-Utah M. Co. at Pioche, E. Freudenthal superintendent, is to be developed through the old Meadow Valley No. 5 shaft. The old engine is being replaced by a smaller one, which will be used for all the preliminary work of retimbering and sinking to the 2000-foot level.——At the Abe Lincoln the mill is putting through twenty-five tons per day of $25 ore and making a high-grade concentrate for shipment, while the Holderman plant is successfully extracting the gold values from the tailings. —— On the North Pole property at Pioche men are running a 350-foot tunnel and the shaft is to be sunk to the 1000-foot level. This is the property of the new Boston–Pioche M. Co. that has been organized by Scott & Miller. —— The Mendha is being developed through a winze from the tunnel level. —— Bullionville is to be revived through the operations of the Godbes and J. L. Hackett of Louisville, Ky., who has purchased an interest in the tailings there. They will run through the big pile, which averages $16 per ton, by a new process, and expect to make a saving of $5 per ton on the 170,000 tons they have there. They will also work over the pile of tailings that still remain at the old millsite in Dry valley, east of Pioche.

NEW MEXICO.

Luna County.

The Phœnix Prospecting Co. has let a contract for a 250-foot tunnel on the Dewey and Olympia, at Cooks. The tunnel will tap the ore body at a depth bf 680 feet.

Otero County.

The Standard Lithographic Stone Co. has developed its quarries sufficiently at Highrolls to be in position to quarry solid stone in sufficiently large pieces to be of commercial value.

San Miguel County.

W. S. Standish is erecting a mill at Ribera, on the Santa Fe Railway, for the treatment of silver, gold, silver and copper ore from the Glorieta range.

Sierra County.

The Black Peak M. Co. has resumed work and will put in a 10-stamp mill, a 25 H. P. gasoline engine and a gasoline hoist, purchased by W. W. Williams, the manager.——The Union Esperanza mine, at Shandon, has received the piping for its hydraulic plant, and also some of the machinery.

OREGON.

Baker County.

The Oregon Dev. Co. has leased ten stamps of the Cracker Oregon mill at Bourne for treatment of ores from the Taber Fraction mine. It is the intention to haul the ores by wagon, and in the meantime surveys will be completed for an aerial tram from the mine to the mill.

At Cornucopia, in addition to the work of the Cornucopia Mines of Oregon Co., under Manager Humbert, the Queen of the West, under the management of C. F. Soderling, and the Mayflower, under the direction of G. W. Boggs, have ordered 10-stamp mills.

Grant County.

Jos. Waddell, manager Prairie Diggings mine, owned by the Jupiter G. M. & M. Co., states that since resuming work this season 200 feet of drifting has been done on the 175-foot level. Deep sinking has been resumed to extend the shaft to the 350-foot level.

The Blue Channel Placer Co. are working on Big creek, near Susanville, with J. K. Zimmerman as manager. A shaft has been sunk 125 feet and 600 feet of drifting done on the old channel. The gravel is washed in 150 feet of sluice boxes with Hungarian riffles.

Josephine County.

Early work at the Takilma smelter has been to the satisfaction of Manager Walters.——At Wolf creek the Martha mine, owned by the Greenback Co., work for which is being done on the Coyote side of the Coyote–Grave creek divide, has been equipped with a compressor, by means of which Manager R. N. Bishop is driving adit levels on the vein. The lower drift is in 1300 feet.

W. E. Williams, manager Buckeye M. Co., reports ore carrying gold, copper and nickel in the Buckeye mine, near Grants Pass.

O. A. Halladay is visiting the stamp mills of Grants Pass with a view of selecting the kind of a mill they will put at the Michigan mine. They intend to put in a 10-stamp mill.

Considerable dredger prospecting is being done near Grant's Pass. Several years ago a dredger was built on the China diggings, near Waldo, and run for a short time, but became involved in litigation and has since been idle. While in operation it was said to be a success. ——A Seattle company has been on Sucker creek, in the south end of Josephine county, for over a year prospecting a tract, and has gone over the ground for 4 miles. The work has been done by a series of open cuts or holes; a pump was used to keep water out while the men are at work. This company insists that drills do not give so fair a test of the ground as hand work. Recently a larger engine and pump were installed to continue prospecting.——T. W. M. Draper has had a drill at work for some time near Waldo, and is testing the gravel at the Reames & Wimer mine also.——J. T. Layton has bonded his placer mine on Farrin gulch to an Oroville, Cal., dredging company for $60,000. There are 400 acres of red gravel running up the creek, which is from 10 to 30 feet deep. The mine is operated with water from Williams creek, by means of two ditches, 13 and 22 miles, respectively, in length. It is also equipped with a large reservoir. This mine has been operated for the past thirty years and has been a heavy producer. The gold runs from $16 to $17 an ounce. The company has also secured a bond on the land of E. N. Provolt for $10,000, and the farm of L. C. Hyde has been bonded for $4000. ——On Evans creek, near Wimer, an Eastern company has secured a bond on several hundred acres of land and proposes to install a dredger. J. W. Boileau of Pittsburg and I. F. Peirsel of Brownsville, Penn., have inspected the property.

SOUTH DAKOTA.

Pennington County.

Geo. Bain has started unwatering the Dolcode shaft, near Hill City.——F. C. Crocker is putting in an air compressor, pump, etc., to develop his mine.——The Dakota–Calumet Co., near Sheridan, are putting in a new boiler and pump and will resume sinking.

Custer County.

The Interstate M. Co. has resumed work, 10 miles northwest of Custer, and will sink the main shaft to the 100-foot level.

Lawrence County.

The Homestake Extension Co. has put in a new air compressor at the property, near Deadwood. The company plans to run a crosscut tunnel 550 feet to cut a vein outcropping on the surface.——It is understood that Manager A. J. Simmons is to put in new machinery at the Echo mine, near Maitland.——The Golden Reward M. Co. have temporarily closed the mill at Deadwood, to put in a new ore dryer at the mill.

UTAH.

Garfield County.

Three miles from Salina two salt mines are in operation. At the Jennings mine a shaft, 6x9, has been sunk through a depth of 75 feet. A ditch has been constructed into which the water can be pumped and carried away, but this has been a laborious and unsatisfactory plan, and the intentions are to drain the quarry by running an incline drift from a sufficient depth into the adjacent shaft, where the water may find an outlet by seepage or be pumped to the surface. From 24,000 to 50,000 pounds of rock is shipped every day.

Grand County.

Near Basin, in the La Sal mountains, Wilson mesa is being prospected by companies headed by J. R. Emmett and M. Mason. Each company proposes to put in a cyanide plant to treat float ore.

Juab County

The shipments from the Tintic district for week ending June 30 amounted to 121 cars, distributed among the following shippers: Swansea, 8; Eagle & Blue Bell, 10; Yankee Con., 6; Victor, 10; Grand Central, 3; Carisa, 5; Mammoth, 11; Ajax, 2; Bullion–Beck, 6; Gemini, 14; Centennial–Eureka, 46. Total, 121.

Piute County.

(Special Correspondence).—The Sevier Con. G. M. & P. Co., 1½ mile from Kimberly, are preparing to erect a new 125-ton concentrating and cyanide mill. The old 10-stamp mill has been out of commission for some time. The present company has been operating the property for years through tunnels and open cut. No. 3 tunnel cuts the vein 960 feet below the surface. The directors of the company will hold a meeting July 5, and determine at that time the kind and size mill to be erected. R. W. Foster is manager and W. Christensen superintendent.——The No. 5 tunnel of the Annie Laurie M. Co. is in 3500 feet and connections made with the No. 4 tunnel 430 feet above. The mill of the company has a capacity of 250 tons per day. On account of the spring inflow of water in the chutes, it causes the ore to become wet and the capacity of the mill to be retarded. Within a short time they expect to have the mill handling the usual amount of ore. The company is putting in a steam plant at Sierra station, on the railroad, and stringing wires to the mine, and will operate with electric power. S. M. Levy is general manager, O. Wiser mill superintendent, D. C. Williams mine superintendent and A. W. Russell superintendent cyanide department. On account of this camp being so remote from other mining districts, it is hard to get good men in the mine.

Kimberly, Utah, July 3.

G. H. Pidd, who has the contract for driving the tunnel on the Golden Treasure M. & M. Co.'s property at Gold mountain, south of Kimberly, reports that the tunnel is in 300 feet and at a vertical depth of 150 feet. The company has over 5000 feet to run on the lead before reaching the claims included in the Golden Treasure.

Salt Lake County.

Manager Cates of the Boston Con., at Bingham, has started work on two new tunnels, designed to develop the porphyry ground. One of these is on the Metropolitan claim. On the Ben Hur another tunnel has been started. These tunnels, with the Teck tunnel and other workings, will prospect the porphyry at depth. The Teck tunnel is in 850 feet and is going forward at the rate of 180 feet a month.——At the Little Eddie Manager McCarrick has completed a raise to the hanging wall, a distance of 22 feet.

Utah County.

The activity in prospecting and opening up mineral claims in the mountains east of Provo continues. Woodward Bros., who have contracts on the Buckley mine, in Rock canyon, and the Tidal Wave, between Provo and Springville, are working both properties. In the Buckley mine the upper tunnel has passed through a 10-foot horse of lime and opened up chlorides and crystallized lead. The winze to connect the upper and lower tunnels is down 105 feet. When connection is made shipments will be resumed, the ore being dropped from the upper to the lower tunnel, in which manner it can be handled to much greater advantage than by taking it out through the upper tunnel.——The tunnel on the Tidal Wave claim is in 180 feet.——The Moore Bros. of Provo are opening up a vein of gray copper on the north of the Tidal Wave, and the Red Rose, on the south, has a showing of red oxide of copper.——B. F. Smith of Thistle reports work being done on a vein of low-grade ore on land belonging to him.

WASHINGTON.

Snohomish County.

Operations have been resumed at the Forty-five mine, near Silverton, after an idleness of four years because of litigation. It is stated that the Pinkhams of Boston have bonded the property to Eastern capitalists: that $50,000 is to be spent in improved equipment, including a compressor, and in development work, and that an electric line 24 miles in length, from Sultan on the Great Northern Railroad, and a large concentrator are to be built if conditions justify. Lee & Stoess of Seattle have charge.——The Packard M. Co. is putting a 2-drill compressor on its Rantoul property at Monte Cristo.——The first shipment of 40 tons from the Sidney mine, Monte Cristo, has arrived at the Everett smelter. F. W. Peabody has charge.

WYOMING.

Carbon County.

The smelter of the Penn-Wyoming Copper Co. at Encampment has been started after several months spent in overhauling the reduction works. There are forty-five men on the tramway, which has also been put in readiness for the delivery of 500 tons of ore per day. The capacity of the crushing department has been doubled by the addition of a new crusher, together with a new system of screens and classifiers. It is capable of crushing to a ⅜ inch mesh 500 tons of coarse ore per day. By means of elevators, the crushed ore is put through screens, oversize being taken up and returned to be recrushed. From the screens the ore is again elevated to the rolls floor, where it is put through four large sets of rolls and pulverized finer. This product is then elevated and passed into the new Hancock jig. This year the company intends to keep both furnaces in blast and the converters running at the same time, treating 500 tons of ore and making about 30,000 pounds of copper per day. In circulars the Penn-Wyoming Co. is sending out, the company outlines a plan for the erection of a concentrating plant capable of handling 1000 tons of ore daily at a point between Dillon and the Ferris-Haggarty.

FOREIGN.

AUSTRALIA.

Victoria.

In the Castlemaine district there are said to be twenty-four dredgers, employing between 500 and 600 men. At one place the orchardists are obtaining permission from a local company to run the slime from the settling pits over the gardens, it being found a very useful fertilizer. In the plant put up by the Yarronru Co. it is proposed to carry the dirt into a large box well by the ordinary sluicing process, after which it will be taken by buckets to a raised concentrating table. Before reaching the table the material is refined by a grizzly, together with a system of revolving screen and fine gratings. It is claimed that the system is rendered necessary by the amount of pyrites and concentrates in the material to be handled.

CANADA.

BRITISH COLUMBIA.

East Kootenay District.

The new 30-drill air compressor for the St. Eugene, at Moyie, has been put in.——The Aurora mine, near Moyie, has been bonded to W. Mackay and R. Wilson of Portland. John Sullivan of Portland will be the manager.

Boundary District.

For the week ending July 1 the Boundary ore shipments were: Granby mines to Granby smelter, 12,680 tons; Mother Lode to British Columbia copper smelter, 2200 tons: Mountain Rose to British Columbia copper smelter, 358 tons; Emma to Nelson smelter, 187 tons; Oro Denoro to Granby smelter, 132 tons; Skylark to Granby smelter, 30 tons; total for week, 16,578 tons; for year, 459,421 tons. Boundary smelters treated the following tonnage this week: Granby smelter, 12,940 tons; British Columbia copper smelter, 3965 tons; total for week, 16,905 tons; for the year, 470,850 tons.

Granby's two new furnaces at Greenwood are expected to be ready for service soon. When they are blown in they will enlarge the capacity of the plant 40%, and the management believes that they will make possible an increase of 50% in the company's copper production and net earnings. At present Granby is making an average of 1,300,000 pounds of copper and earning $80,000 net monthly. Its copper is costing, all expenses of refining, selling, management, taxes, etc., included, between 8 and 9 cents per pound. One month recently the cost figured 8.03 cents per pound. It is the intention of the management to ultimately increase Granby's production to 5000 tons of ore daily. The Granby vein is 700 feet wide, and is a self-fluxing smelting ore. The ability to handle this ore — including mining, transportation, smelting, converting, refining, selling and management — for $3.50 to $3.75 per ton has already been demonstrated. As the ore yields about twenty-six pounds of fine copper and $1.75 in gold and silver to the ton, it has a present average value of about $5.50 per ton.

Slocan District.

In the Ainsworth district, at the Krao, Manager Wheeler has increased the force at the mine and is putting up buildings.——The United mine, near Ainsworth, has been pumped out by zinc-ore men, and sampling and analysis is now in progress.——The returns from a recent shipment of 21½ tons of silver-lead ore from the Whitewater, at Whitewater, averaged 110 ounces silver and 45% lead.——The Slocan Star mill, near Sandon, is crushing 25 tons of zinc ore daily. Good progress is being made at the mine, and the mill is working smoothly. Water is plentiful, and the large tonnage of concentrating ores on hand will keep the mill working to its full capacity. The Slocan Star is owned and operated by the Byron N. White Co. of Milwaukee, Wis., with O. V. White manager at Sandon. The mine has been opened up by five levels, all entered by crosscut tunnels. Chas. Culver has charge of the mill.

Vancouver Island.

It is reported that all the mines of the Western Fuel Co. on Vancouver island will be closed down. The issue between the miners and company has been shifted and from now on it will be a fight for recognition of the union. Owing to the refusal of Superintendent Stockett to receive a committee from the union, the workers in the company's mine at Brechin laid down their tools and walked out June 30.

CENTRAL AMERICA.

Panama.

Consul-General Lee, at Panama, has notified the State Department of the passage of a resolution by the council of Republic of Panama, holding that all mines, whether found under the surface of private property or not, belonged to the government of the Republic.

MEXICO.

Zinc ores are but little known in Mexico; at least, in the shape of calamine, though blende abounds in all the mining region; but the heavy expense necessary for its exploitation has thus far prevented the extraction of the metal on any considerable scale. In the mining districts of Xochiapulco and Xochitlan, in the State of Puebla, blende is often found. Taxco, in Guerrero, contains blende in large quantities, mixed with argentiferous ores, which compound also occurs in Mazapil, Sombrerete, and Plateros, in Zacatecas, whose rich deposits justify the working for zinc, apart from the silver contained in them. In the Remedios, Jalisco, there are beds that might be profitably worked, and in Comanja, of the same State, blende forms the main component of argentiferous lodes.

Chihuahua.

(Special Correspondence).—The Sierra de Almoloya, half way between Jimenez and Parral, are a Cretaceous limestone, with a northeast and southwest trend. The faulting and fracturing of the range have produced large caves, in which the ores are found, the values apparently having been leached out higher up in the mountain by the continual seepage of water through the lime, and redeposited in their concentrated form below. On the largest fault plane which passes through the mountain are the San Enrique, Cigarrero and Iguana mines. The ores are similar to those of Santa Eulalia, but carry a larger quantity of iron and are much richer in silver and gold.

While the output of the Sierra de Almoloya is comparatively recent, yet in the early seventies the old Spanish adobe smelters, in treating the lead-silver ores of Parral and Santa Barbara, found in this range low-grade surface ores containing a high percentage of iron and manganese, which they used for fluxing, transporting the ore over 40 miles on burros. With the passing of these primitive smelters the range was neglected until recently a 300-foot shaft has been sunk on the Cigarrero and crosscut run, which has opened up lead carbonate carrying silver and gold. East of the Cigarrero, and on the same fault plane, the San Enrique mine contains outcrop of copper, iron and galena. There are two shafts and four tunnels. West of the Cigarrero, and under the same management as the San Enrique, is the Perro Colorado, upon which six shafts have been sunk and one tunnel run. East of the Perro Colorado the Iguana is shipping two carloads of high-grade ore daily. Three shafts are being sunk on the Baja California mine, at the western end of the range, and at a depth of 15 meters ore has been struck carrying silver, gold and 30% lead. Ore has been shipped from the Hercules, Huerfano, Zacatecas, Mina de Agua and Chihuahua mines, while the development of the San Juan and Nicolas Bravo properties, at the western end of the range, shows that with depth the value and quantity of ore increase. On the southern side of the mountain the Julietta mine is shipping ore containing neither lead nor silver, but which averages three ounces gold to the ton. The La Fragua has shipped high grade ore. The copper in the deeper workings indicate that with depth the Sierra de Almoloya will develop into a great copper producer.

Baca, July 1.

B. W. Bourne of Los Otates has sold the La Cruz and Santa Nino gold-silver mines at Los Otates to Boston people, represented by J. Swayne.

Durango.

The most important Mexican tin mines are in the Coneto region, 36 miles south of Inde, near the Sierra of San Francisco. The predominating formation is calcareous trachyte, and the beds, which are of vast extent, if properly worked, could not fail to give large returns, the ores yielding 35% to 75% of metal, most of them in the form of oxides. In the Sierra Bacaria is found, also in trachytic rock, tin ore associated with arsenic, bismuth, iron and tungsten, carrying from 18% to 23% of metal.

Guanajuato.

Tin is found in the Guanajuato district, at Mesa de Moreno, Cacachilas, Cerro Macho, Estanera, Rancho, Estrada, Mesa Encina, and Presa Arroyo in Allende, and in Jaralillo and Estancia in the district of San Felipe. Most of the metal found in Guanajuato is rarely appearing in veins.

Jalisco.

The tunnel to cut the veins of the mines of the San Pedro Analco M. Co., 20 miles from Hostotipaquillo, has been commenced. It will be 11,375 feet in length, and will be 10 feet high and 6½ feet wide. The veins will be cut at a depth of 2000 feet, and the tunnel will provide drainage as well as transportation facilities.

Sonora.

The San Rafael C. M. Co. has been formed to work the San Rafael mines, 16 miles northeast of Hermosillo. T. E. Monteverde Jr. of Hermosillo is president; H. J. Smith, cashier of the Banco de Sonora, is secretary and treasurer. A. H. McKay of Santa Barbara, Cal., is interested. It is stated that the concern will build two reverberatory furnaces at the mines.

The chief coal region of Sonora is 100 miles from the River Yaqui, and forms an oblong basin surrounded by mountains, in which devonian and silurian formations predominate. This basin has neither valley nor plains within it, but the ground presents elevations, within which the coal layers overlay a stretch of country nearly 7000 square miles in extent. The first of these layers appears on the Soyapa river stretching toward the south, to the left margin of the Yaqua river, which cuts it in its course; it then traverses Tomichi, Oantos and Moba, running to the southwest as far as Buenavista. Coal beds succeeding each other are visible in all the glens near La Barranca, overlaying the fells as far as the town of Cuaqui. The eastern brows of the Pilares ridge show coal measures of different dimensions, more or less decomposed in the exterior. Within the carboniferous belt there are deposits of gold, silver, copper, iron and other metals. The metalliferous formations reach to a depth of from 200 to 600 feet, where the primitive carboniferous layers appear, which, as a formation anterior to the rocks carrying the ores, cause all traces of the latter to be entirely lost. The coal in this part of Sonora is known as anthracite, but noted for the absence of sulphides and such other minerals as detract from the quality of the Pennsylvania coal fields, iron and lime being the only foreign substances which it contains. Coal has been known to exist in these regions for thirty years.

At the Chicago mine, between San Javier and San Antonio de la Auerta, the Chicago & Sonora M. Co. are working forty men and operating their 4-stamp mill upon high-grade gold ore.

Tepic.

J. B. Mulhall and R. C. Hawley are developing mines near Amatlan de Canas, and are shipping ore to the smelters. A tramway is to be built from the mines to the Mexican Central Railway in San Marcos, Jalisco.

Vera Cruz.

Platinum is said to be found in Zorra, Ixtatetla and Huastequillo.

Personal.

B. S. REVETT has returned to Denver, Colo.

J. P. CHANNING is examining mines at Ely, Nev.

J. NAGLE is superintendent Vega M. Co., near Gabilan, Sonora, Mexico.

J. A. CLARKE of Keystone, S. D., has been on a business trip to Michigan.

W. V. RICE has returned to Salt Lake City, Utah, from a visit to Montreal, Canada.

E. A. WEINBERG is examining tin mines at Herberton and Irvinebank, North Queensland.

A. F. WUENSCH has resumed his practice as mining engineer at 414 Exchange Bldg., Denver, Colo.

F. J. TOUSSAINT has returned to La Chumata mine, Arizpe district, Sonora, Mexico, from Milwaukee.

O. B. AMSDEN, superintendent Clover Leaf mine, has returned to Roubaix, S. D., from an Eastern trip.

W. M. LEWIS has been appointed resident manager St. Paul & Colorado M. Co., near Georgetown, Colo.

RHOADES FISHER, JR., has been appointed a member of the engineering staff of the Juragua M. Co., Fersneza, Cuba.

CHAS. LAWTON has resigned as superintendent Bingham Con. mines, at Bingham, Utah, to return to Michigan.

M. G. ESTABROOK of Boston, Mass., has been at Joplin, Mo., looking after the interests of the Amalgamated Zinc & Lead Co.

W. F. SNYDER has returned to Salt Lake City, Utah, after examining the Western Exploration Co.'s mines in Shasta county, Cal.

WM. DAVEY, formerly superintendent Yampa mines, near Bingham, Utah, is practicing as mining engineer at Salt Lake City, Utah.

HERBERT HAAS has resigned as superintendent Great Western Gold Co., Shasta county, Cal., and will open offices in San Francisco.

J. K. BRUNNER, vice-president and general manager Golfo de Oro G. M. Co., has returned from Colorado Springs to La Dura, Sonora, Mexico.

W. F. V. YOUNG of England has succeeded Thomas Clearage as manager of the dredger on Gold creek, Mont., 30 miles northwest of Basin.

H. H. NICHOLSON has resigned as professor of chemistry and director of the School of Mines and Metallurgy, University of Nebraska, and will, henceforth, devote his entire time to his mining business.

VICTOR G. HILLS has been appointed consulting engineer and general manager of the Colorado Tungsten Corporation, a Pittsburg, Pa., company, operating wolframite veins in Boulder county, Colo., mines at Nederland, Colo., and mill at Boulder, Colo. Charles P. Oliver, former superintendent of Dead Pine mine at Cripple Creek, goes as superintendent of the mine at Nederland. D. J. Badger, formerly in charge of the concentration tables department of the Standard mill at Colorado City, Colo., becomes superintendent of the mill at Boulder.

W. A. STADELMAN, Eastern agent Wellman-Seaver-Morgan Co., and who has been in charge of the Eastern office at 42 Broadway, New York City, has been appointed general sales agent of the same company, with headquarters at Cleveland, O., taking effect July 1. Fred Stadelman has been appointed assistant manager of the New York office Wellman-Seaver-Morgan Co. Harry V. Croll, M. E., formerly with E. P. Allis Co. and their successors, Allis-Chalmers Co., of Chicago, has resigned and accepted a position with Wellman-Seaver-Morgan Co. of Cleveland, O.

Books Received.

"Forest Conditions in the Gila River Forest Reserve, New Mexico," by T. F. Rixon, are described in Professional Paper No. 39.

Professional Paper No. 35 of the United States Geological Survey gives the "Geology of the Perry Basin in Southeastern Maine," by G. O. Smith and D. White.

As extracts from "Mineral Resources of the United States for 1904," the United States Geological Survey has issued, "The Production of Bismuth in 1904" and "The Production of Fluorspar and Cryolite in 1904."

"The Copper Mines of Lake Superior," 160 pages, 8vo., is an intelligent and interesting discussion and description of mining methods in northern Michigan copper mines. Its author is T. A. Rickard, late editor of the Engineering and Mining Journal, a writer who apparently never touched a subject that he did not adorn, and whose printed words are no less noticeable for their technical accuracy than for the charming literary style that is the delight of his readers. This fine book will add to his reputation in both regards. It is to be considered the latest word on the several subjects of which it treats, and as such deserves cordial commendation.

"Transactions of the Australian Institute of Mining Engineers," Vol. X, edited by A. S. Kenyon, secretary, Melbourne, Australia. J. W. Gregory has contributed a masterly paper on "The Mount Lyell Mining Field, Tasmania, with Some Account of the Geology of Other Pyritic Ore Bodies." Other papers are: "Prospectuses," by President F. D. Powers; "Concentration of Lead Silver Ores," by V. F. S. Low; "Phosphate Deposits of Ocean and Pleasant Islands," by F. D. Powers; "Coal and Coal Mining in New South Wales," by Thomas Parton; "Method of Timbering at the Mount Rex Tin Mine, Ben Lomond, Tasmania," by Mark Ireland; "Peck's Centrifugal Elevator," by W. Peck; "A Portable Assay Furnace," by J. J. Gillio; "Notes on Sampling," by A. C. Thomas; "The Career of the Gold Dredge in New South Wales," by D. K. Blair; "The Transmission of Power by Compressed Air in Mines," by R. W. Chapman; "The Misplacement of Mining Shafts and Adits in Victoria," "The Indicators of the Daylesford Gold Mines, Victoria," "Mining Accounts," by R. N. Kirk.

Commercial Paragraphs.

THE S. H. Supply Co., Denver, Colo., report sales of American air compressors, for which they are the Western agents, to the Bleak House M. & Dev. Co., Eagle county, Colo., a company in Clear Creek county, Colo., and another to Idaho. With each of the above machines was furnished all additional necessary machinery.

THE Santa Fe, Prescott & Phœnix Railroad will become part of a trunk line of the Santa Fe systsm. A line is being constructed from Wickenburg, Ariz., to the Colorado river and will be extended to the present main line of the Santa Fe at Daggett, Cal. The Phœnix & Eastern Railroad is being extended eastwardly across Arizona to unite with the Santa Fe line at Silver City, N. M. Another line will be built at Rincon, N. M., to San Angelo, Tex., connecting with the Santa Fe line at Pecos, Tex.

SMOOTH-ON ELASTIC CEMENT is the latest preparation of the Smooth-On Mfg. Co. This is an iron elastic cement prepared in paste form, ready for use. Its advantages are, that it is metallic and can also be applied to hot iron, the heat causing it to metallize instantly, making it invaluable for stopping leaks. Their new Smooth-On elastic cement instruction book will be sent free of charge by addressing Smooth-On Mfg. Co., Jersey City, N. J.

SEVERAL changes have been recently made in the engineering staff of the Colorado Iron Works Co. of Denver, Colo., a notable one being the transfer of John E. Rothwell from the main office at 33rd and Wynkoop streets to the city sales office at 515 17th street, at which latter place he will have charge. Mr. Rothwell is well known to the profession through his writings in the technical press and his work as a mechanical engineer and metallurgist, chiefly in connection with the barrel chlorination process. With an experience of over twenty years in milling and metallurgical operations, during which time he has designed and built a number of successful plants in various parts of the country, he is qualified for the position to which he has been appointed. The company states that Mr. Rothwell will be at the service of all who may desire advice or suggestions on milling and metallurgical subjects.

Obituary.

J. WATERS, a prominent Morenci miner, died June 27th at Morenci, Ariz., from miners' consumption.

F. H. DAVIS, superintendent Midvale Steel Co. of Germantown, Pa., died suddenly June 22nd, at Great Barrington, Mass.

J. E. DOOLITTLE of San Francisco, Cal., died on July 4th, at the Union League Club, in San Francisco, of heart failure. He was an extensive mine owner and operator in California, and was a trustee of the California State Mining Bureau.

FRED ZEITLER, a prominent mining man of Nevada county, Cal., has been missing for ten days under circumstances that make it manifest that he is dead. Searching parties have traversed the entire county with no result and it is now almost certain that he has perished. Mr. Zeitler was formerly manager Champion mine, Nevada City, Cal., first vice-president California Miners' association and superintendent Ziebright mine.

Trade Treatises.

Form 73 A, "Air Lift Pumping," from the Ingersoll-Sergeant Co., 26 Cortlandt St., New York, has some happy hints on that subject.

Latest Market Reports.

SAN FRANCISCO, July 7, 1905.

METALS.

SILVER.—Per oz., Troy: London, 27d (standard ounce, 925 fine); New York, bar silver, 58⅝c, refined (1000 fine); San Francisco, 58¾c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.00; Lake, 1 to 3 casks, $15.00@15.25; Electrolytic, 1 to 3 casks, $15.25; Casting, 1 to 3 casks, $14.50@14.75. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £66 spot per ton.

The demand for copper from Asiatic points is reported dull, but large future purchases are anticipated. The market remains firm, with no notable change in quotations. The war in the Orient has been a factor in the copper market, but it is not nearly so important as the demand for the metal due to the expansion of industrial activity due to peace and prosperity in other countries.

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.12½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £13 8s 9d ℔ long ton.

SPELTER.—New York, $5.30; St. Louis, $5.70; London, £23 17s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $30.65@31.00; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, ℔ lb., 35@37½c. London, £140 2s 6d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $19.50 ℔ Troy oz. Platinum ware, 75@82c ℔ gram.

QUICKSILVER.—New York, $39.00@$40.00, large lots; London, £7 7s 6d; San Francisco, local, $38.00@38.00 ℔ flask of 75 lbs.; Denver, $45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.75c; San Francisco, Plumbers', 100-lb. lots, 17.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.60; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3¼c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $23.00@$23.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7¼c; San Francisco, 1000-lb. lots, 9c; 300@500-lbs. 9¼c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17¼c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ℔ set; 14 oz., 40s., 9¾c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3¼c ℔ lb.; caustic soda, in drums, 3@3¼c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 62c; cs., 67c; raw, bbl., 60c; cs., 65c; Lucol oil, boiled, bbl., 54c; cs., 59c; raw-bbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

MOLYBDENUM.—Best, $2.75 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

URANIUM.—Oxide, ℔ lb., $3.50.

MERCURY.—Bichloride, ℔ lb., 77c.

TUNGSTEN.—Best, ℔ lb., $1.25.

PHOSPHORUS.—American, ℔ lb., 70c.

SODIUM.—Metal, ℔ lb., 50c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MAGNESIUM.—Pure, N. Y., $1.60.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JUNE 27, 1905.

793,171.—CHAIR—A. A. Bartlett, San Francisco.
793,541.—PUMPING APPARATUS—W. W. Belknap, Stockton, Cal.
793 502.—SPRING MOTOR—W. J. Bell, Los Angeles, Cal.
793,342.—TROUSERS CREASER—O. Bernard, San Francisco.
793,275.—SOLAR GERMICIDE—L. A. Cain, Lompoc, Cal.
793,419.—VALVE HOLDER—C O Cole, Bellingham, Wash.
793,421.—DOOR OPENER—E. E Combs, San Francisco.
793,284.—ROLL PAPER PRINTER—J. D. Donovan, San Francisco.
793,126.—STAMP AFFIXER—S. Farmer, Portland, Or.
793,280 —UNDER REAMER—R. S Futhey, Los Angeles, Cal.
793,522.—WRENCH—L. G. Heal, John Day, Or.
793,372.—VEHICLE AXLE—C. Heilrath, Sacramento, Cal.
793,587.—POLISHING MACHINE—A. C. Johnson, Baker City, Or.
793,528.—INDICATOR - H. Kirch, Santa Rosa, Cal.
793,381.—SNAP HOOK—J. C Kortick, San Francisco.
793,451.—DISPLAY RACK—Lindsay & Burch, Seattle, Wash
793,141.—SHOE POLISHER—F. E. Marshall, Porterville, Cal.
793,207.—ROTARY ENGINE—L. A. Miley, Seattle, Wash.
793,209.—HOSE COUPLING—W. C. C. Miller, Vacaville, Cal.
793,385.—DUMP CAR—A. Mieden, Seattle, Wash.
793,312.—TROLLEY POLE—A. W. Morgan, Long Beach, Cal.
793,225.—VEHICLE—A. Perisch, Stockton, Cal.
793,400.—RIFLE CLEANER—G. A. Sachs, Eugene, Or.
793,161.—SEWING MACHINE—A. Sandmeyer, Yakima, Wash.
793,236.—AMUSEMENT DEVICE—M. L. Schlueter, Oakland, Cal.
793,103.—PIPE COUPLING—J. Scholtz, San Francisco.
793 240.—DISK PLOW—G Spaulding, San Francisco.
793,473.—CHECK REGISTER—D. W. Thornton, Sumpter, Or.
793,248.—NUT LOCK—Thrift & Louttit, Stockton, Cal.
793,118.—WATER HEATER—Wright & Sager, Seattle, Wash

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

PUMPING APPARATUS.—No. 793,341. June 27, 1905. William W. Belknap, Stockton, California. This invention relates to a pumping apparatus which is especially designed for raising quantities of water to a comparatively low elevation and a means for connecting a horse power with such an apparatus, so that the power may be applied in a substantially equalized manner to produce a continuous flow of water. The apparatus consists of the combination of horizontally disposed pump cylinders, a compartment valve chamber for each cylinder located at one side thereof, and pipes connecting the separate compartments of the chamber with opposite ends of the cylinder, a supporting frame, a vertical crank-shaft located on the frame essentially midway between the cylinders, pistons operab e in the cylinders and provided with rods, pitmen connecting said rods with the cranks of the shaft, a socket at the upper end of the shaft, said socket having an extension or hub portion adapted to receive the upper end of the shaft and having its opposite portion adapted to receive the sweep.

SNAP HOOK.—No. 793,381. June 27, 1905. John C. Kortick, San Francisco. This invention relates to an improvement in hooks of that class known as "snap-hooks," and it consists in a novel construction and operation of a tongue or keeper in connection with the hook. Its object is to provide a hook through which detachable connections are made with harness or other parts, and which it is desired to engage or disengage. It comprises a shank having a rectangular opening, a spring fitting said opening, a keeper having downturned sides inclosing said opening in the shank, a fulcrum pin connecting the keeper with the inner side of the shank, said shank having a portion of its edge curved in an arc concentric with the pin, and said keeper having its back adapted to move in contact with said arc when the keeper is opened or closed, and a second pin carried by the keeper and passing transversely through the shank and said opening for engaging the spring.

MINING AND SCIENTIFIC PRESS.

Whole No. 2347.—VOLUME XCI. Number 3. SAN FRANCISCO, CAL., SATURDAY, JULY 15, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Deep Mines vs. Superficial Deposits.

The term "true fissure vein" has come to be regarded by many as the synonym of permanency and richness when speaking of a mine. Notwithstanding the fact that fissure veins do not always continue uninterruptedly to depths which are readily reached by mining operations, and that they are not always large and rich, still the average miner delights to believe his vein is a "true fissure," and usually persuades himself that it is really such. Many fissures are of great continuity, width and richness. Some of the veins of the California Mother Lode are excellent types of fissures—rich, large and of great depth. A notable example is the Eureka vein, at Sutter Creek, worked to a depth of about 2200 feet and having produced $18,000,000 in gold. Another is the Idaho–Maryland vein, at Grass Valley, worked to a depth of nearly 2000 feet vertical and which produced over $25,000,000. The Smuggler – Union of Telluride, Colo., is another example, and these may be multiplied many times by others equally characteristic. The Comstock, Nevada, is a series of complex fissures. The Homestake and Treadwell are not fissures, but zones of fracture and impregnation; and of this type there are examples innumerable, showing that the fissure vein alone is not the only type of vein that pays. The banket on the Rand, in South Africa, is neither a fissure nor a zone of fracture, but rather a bed of more or less porous rock fragments, water-worn and angular, in which mineral solutions have deposited their gold values.

Without doubt the preference for the fissure vein arises from the idea of great permanency in longitudinal extent and depth, but more particularly the latter, and the noted examples are pointed out as indicating the possibilities of all fissure veins.

The question arises: "Are fissure veins the most profitable?" The answer is each mine must be considered separately, independent of all others, no two being just alike.

There is no reasoning by analogy when contemplating a vein. A fissure vein may possess every geological characteristic considered essential to the ideal vein of this type and still lack that most necessary feature—value. On the other the hand, ordinarily despised "deposit" may be limited in extent, wholly superficial and yet immensely profitable while it lasts. Surely, a flat sheet of ore of definite length, width and depth, the tonnage of which may be estimated to within a few carloads, and which pays a handsome profit on each ton, is vastly to be preferred to the "true fissure vein," with banded structure, clay selvages and smooth striated walls, but without sufficient value to be profitably worked.

The fissure type of vein must have either a tunnel for drainage and ore passage or a shaft which renders the ore bodies readily accessible. Capital must be put into a hoisting plant and into the shaft itself, which alone involves the expenditure of a greater or less amount of money.

The superficial deposit escapes all this expense. It may be necessary to strip a quantity of waste which covers the ore; but generally this undertaking is not expensive. Mining is carried on in the open air and little capital is invested in the enterprise, unless operations are carried on on a very large scale and steam shovels are used. When the latter is the case, the magnitude of the operations usually justifies the expense and mining is consequently cheapened. The accompanying illustration is that of a flat sheet of ore being mined in the Black Hills of South Dakota. The ore occurs in bedded deposits lying upon or in quartzite, and there are many such ore deposits there. The formation in which these deposits are found—the Cambrian chiefly—has been extensively eroded, and canyons have been cut down through the flat, once continuous sedimentary beds, leaving remnants of beds containing the ore, as flat deposits on the hill tops, between the gulches. In some cases the ore is covered by superficial debris, due to disintegration of neighboring higher rocks; in others there lies on the ore a few feet of sedimentary beds, or a sheet of intrusive rock. In still other cases the ore deposits extend down under mountain masses of rock which have escaped erosion. In these underground mining is carried on in the usual manner.

The superficial deposits, however, are mostly readily accessible and are mined as shown in the accompanying illustration, or operations are conducted on a larger scale by the benching system—thousands of tons of ore being blasted down by one series of holes, and the broken ore lifted into cars by means of steam shovels. By this latter method the cost of mining and handling is reduced to a minimum, and a profit is made on ores containing less than $5 per ton.

DRILLING contests have been held recently—mostly at Fourth of July celebrations—throughout the mining regions of the West, and some very good work done by the expert steel polishers. A review of these performances shows in some instances a surprising discrepancy in the inches drilled in the time—fifteen minutes. This certainly must represent something more than the difference in skill between the men. Ordinarily the drilling is done on a raised platform, the material being some firm and homogeneous rock from the immediate vicinity, granite, if available, being generally chosen as being the least likely to present irregularities in structure and hardness; but there is a considerable difference in granite from various places. Some granite contains a larger proportion of quartz than others, and generally the more quartz the greater the hardness. Even solid quartz is often spoken of as "soft quartz," "hard quartz," etc., showing that the miner recognizes the varying degree of facility with which the rock may be drilled. It is not that the quartz of one mass is really softer than that of another, but that the variable structure of the rock is such that some kinds may be much more readily cut than others, and so with almost every kind of rock.

ATTENTION was called last week in these columns to the very low grade of ore being successfully mined and smelted by the Granby Company at their property in British Columbia, where labor is paid at about the same rate as in the United States. Elsewhere herein will be found some interesting data on the operations of copper mines at Mount Lyell, Tasmania, where the conditions are somewhat less favorable than in the western United States. The low grade of some of the ore treated there is interesting as showing what may be accomplished in America with low-grade ores. Some of the ore was so low in grade that hydraulic concentration was impracticable and financially a failure, yet this ore was available in the smelter because it carried the very necessary silica, which the main masses of ore of the Mount Lyell mine lack. The description of the ores and methods of treatment are interesting to all interested in copper problems, and doubtless many others otherwise engaged can find much of interest in a perusal of what is being accomplished in distant regions where there are many disadvantages to overcome.

Hobbies of the Miner.

There are many prospectors and miners who place undue importance upon the value of the presence of some particular rock or mineral. Rich ores of gold, silver, copper and other metals occur under such a variety of geological conditions and in or associated with so many different kinds of rocks and minerals that it is misleading to place too great dependence on any particular sort of geological condition or on the occurrence of any definite mineral. Just at present fluorite is eagerly sought, as it is believed by many to be almost as good as the gold itself. In Cripple Creek district, Colo., associated with the rich telluride ores, fluorite is more or less abundant. So it is in some of the telluride ores of the Black Hills of South Dakota, and more recently it was found to be associated with the gold ores of Bullfrog and Goldfield districts of southern Nevada. The lead fields of southern Illinois and of Missouri, as well as those of England and many other places, abound in fluorite. Fluor is not an uncommon mineral, by any means, and yet it is to-day receiving more attention than ever before, not because of its intrinsic value, but because of its supposed association with gold. A few months ago "luminescent zincblende" had the call, as it was supposed to contain large quantities of radium—a new element of which very little is known as yet, but which is greatly to be desired, as it is at present said to be worth several millions of dollars per pound. Ten years ago the prospector who could find phonolite considered his fortune assured, simply because phonolite was found to occur in Cripple Creek and in the Black Hills associated with gold ores. There are mountains of phonolite in Wyoming and in various other places, and with no trace of gold; but the prospector did not know this, so he earnestly looked for a dark-colored, hard, fine-grained rock, which would "give out a ringing sound when struck." As a result, fifty different kinds of rock were found to possess this peculiarly valuable property, and claims were promptly staked on these numerous "phonolite belts." In most instances the rocks were siliceous slates or other dense metamorphic rocks, any of which would "ring" according to description, but the gold necessary to complete the prescribed conditions failed to appear.

The miner, it seems, must needs have a hobby, or some definite object, to stimulate him to activity, and it might as well be fluorite or radium as anything else. His eager quest usually results in his finding something—gold, silver, copper, borax, or some other valuable mineral—which he can turn to good account. He should investigate every rock, every formation and every possibility. It is a great mistake to search for something "just like was found in some other place," for its duplicate may not exist. There is such great variation in ore deposits, their appearance and surrounding conditions, that the prospector who seeks for a repetition of conditions in any certain place that he may become familiar with in another is almost certain to be doomed to disappointment. Some have a strong predilection for some particular rock or formation, and others have equally strong prejudices against the occurrence of certain minerals or geological conditions. The prejudice against glassy quartz is almost world wide, and yet some very rich gold mines have been developed on veins of quartz almost limpid in its clearness. Much of the gold-bearing quartz from La Fortuna mine, in Yuma county, Arizona, was of glassy, transparent character. On Kinkead Flat, near Sonora, Cal., a vein of almost transparent quartz was rich in free gold. In mica schist the granular, glassy quartz, characteristic of the lenses in that kind of formation, are often rich in gold. Some miners look with suspicion upon a copper mine where garnet occurs with the ore. As against this, some of the most noted and profitable copper mines in the world have abundance of garnet. Others have "no use" for a mine or ore deposit capped by basalt or other late lava. The ore deposit in most cases was formed ages before the flow of lava covered it, and which may have come from a vent many miles distant, and has no connection with the ore deposit whatever.

Great outcrops of milky white quartz are seldom valuable for their mineral contents, though miles of such croppings have been located and industriously developed, but usually without success, and yet there are exceptions worthy of note. In California there have been a number of white quartz veins which were rich in free gold on the surface. The Hite mine, in Mariposa county, was one of these. There a shoot of white quartz, 600 feet long and about 4 feet wide, contained a great deal of visible gold.

To accomplish the best results the prospecting miner must disabuse his mind of all prejudice, and search like an inexperienced "tenderfoot" for mineral deposits. Perhaps this indiscrimination is the reason why so many valuable mines have been found by inexperienced persons. One of the greatest gold mines of the Southwest was discovered a few years ago by prospectors who were operating a dry washer. At noon times they went to the quartz ledge a short distance above where they were engaged to eat their lunch. For two weeks or more they daily sat on the great fortune that awaited them before they realized what it was. The prospecting miner must be a careful observer. Every reef of rocks, hard or soft; every mineral stain; every condition, either strange or ordinary, should be investigated and carefully tested before deciding that it is worthless. All mines do not crop up out of the ground like a great wall; many deposits are in depressions, or in a saddle in the range of hills. Mineral veins usually carry more or less sulphides, and these on decomposing usually cause the country rock to become altered and softened, and as a result both the vein and the walls being softer are more easily eroded than the rock at a distance from the vein, hence the depression. It may be well to have a hobby, but, while pursuing this fancy, do not neglect to observe everything that comes within the range of possible investigation.

A CONTEMPORARY announces the discovery of a valuable ore deposit through the medium of the national game, baseball, in an instance where a player stooped to pick up a ball and discovered a piece of rich ore. On this discovery he later located a claim. This is not the first instance where baseball figured in the discovery of rich ore. On the Iron Hill mine, at Carbonate, South Dakota, some years ago, in preparing the ground for baseball, in setting the home plate, rich chloride ore was found. A shaft was sunk and a rich though small chimney of ore was developed. Strangely, although this shoot of ore went down 300 feet or more, it scarcely extended beyond the limits of the shaft, being an excellent example of the pipe or chimney form of ore deposit. The discovery of the noted Hidden Fortune mine, near Lead, South Dakota, was made on a ball field. The spectators of the miners' games used for years to gather on Otto Grantz' $200,000 worth of gold slugs and watch the progress of the play, though it is needless to say no one had a suspicion of the wealth lying a foot or two beneath them.

THERE still exists in the Black Hills of South Dakota an unsolved metallurgical problem, which, as yet, the skill, experience and technical knowledge of the numerous operators there have been unable to solve—the treatment of the unoxidized or so-called blue ores of the Cambrian beds. Years ago these ores in the oxidized zone presented a most perplexing metallurgical proposition. This was successfully met by the introduction of the chlorination and cyanide processes, but the "blue ore" still resists attempts to gain satisfactory results on the raw ore. Smelting, of course, treats the ore readily enough, but as the ore is highly siliceous it is necessary to associate with it large amounts of pyritic iron or copper ores. The owners of these ore bodies are still working and experimenting with a view to finding a cheap method of recovering the values from these unoxidized ores, and it is not unreasonable to expect that they may yet be successful in their efforts.

GOLDFIELD, the new mining camp which has grown up in southern Nevada within the past year, has not escaped the fate which appears to be the lot of almost every camp of consequence sooner or later. Some of the business center of the town was destroyed by fire a few days since. Houses, tents, merchandise and everything else combustible within reach of the flames quickly disappeared. The usual result follows, and the burned district will be rebuilt with a more substantial class of structures. In a region where water is so scarce, fire-proof buildings are about the best protection against the fires for which Western mining camps are famous.

CONCENTRATES.

BORIC ACID has the composition $B(OH)_3$. This salt forms with sodium hydroxide the borax of commerce. It is obtained from colemanite and other borax-bearing minerals.

♣♣♣♣

WHEN acidulated water or other corrosive liquid must be raised, but which is destructive to metal pumps, an air lift can be installed which will raise the liquid, in the same manner as water.

♣♣♣♣

PLATINA is chemically the same as platinum, although the name platina was also applied years ago to what is now known as Britannia ware, an alloy of tin with varying proportions of antimony and copper.

♣♣♣♣

BY resistance, electrically speaking, is meant something placed in a circuit for the purpose of opposing or resisting the passage or flow of the current in the circuit or branches of the circuit in which it is placed.

♣♣♣♣

UNDOUBTEDLY an air compressor can be operated in a mine on the level where the drills are used, running the compressor by an electric motor. The idea is not altogether new, but it is not in general use as yet.

♣♣♣♣

WHERE tail ropes are used in hoisting, as in the Whiting system, the tail rope is of the same size and weight for given length as the hoisting rope. It permits a constant weight of load at the winding drum.

♣♣♣♣

WHERE lead is present with gold in the solution in a chlorination vat, the lead may be first precipitated by means of sulphuric acid, the lead going down as a sulphate. The solution is then drawn off and the gold precipitated separately.

♣♣♣♣

ONLY coal and iron are not reserved from railroad grants. If land within the zone of the railroad grant can be proven to be mineral before the railroad company secures patent to the land, it may be set aside for settlement by citizens of the United States.

♣♣♣♣

THE new reef of rich gold ore recently discovered at a depth of 2200 feet in the Catherine mine, at Bendigo, Australia, is in old grounds where mines had been worked since 1861 and which were very rich on the surface. The new strike mills over an ounce to the ton.

♣♣♣♣

COPPER ores occur in Triassic and Permian rocks in the form of nodular masses. In most instances, these ore deposits are not connected in any way with dikes, or with notable geological disturbances. Copper ores of this character are found in Utah and Arizona on both sides of the Grand canyon of the Colorado river.

♣♣♣♣

BOTH turntables and turnplates are used underground. The former is more likely to become clogged with debris and cause trouble. A good plate is usually satisfactory, and, if properly laid and provided with guide corners, will answer every purpose. In dry mines a good turntable will work better probably than in a wet level.

♣♣♣♣

IT is not always necessary to have a constant maximum supply of fresh water for milling operations, as where a limited supply is available the water may be settled and reused in the mill. The loss from evaporation, absorption, and that carried away in pulp or concentrates, is usually between 25% and 50%, the loss being proportionally greater where the operations are on a small scale.

♣♣♣♣

AN element of danger in working ore deposits by the room and pillar method is in leaving the same size of pillars in a large deposit as were found to be satisfactory and safe in a small deposit. A vein 15 feet thick may be safely worked by leaving pillars of a stated size, but pillars of this size would not, perhaps, sustain the roof of a deposit 30 feet or more in thickness. The pillar must be increased in size.

♣♣♣♣

IN the application of the cyanide process it is often economy to provide a large tankage facility and to increase the time of contact in percolation treatment, thus getting a higher percentage of extraction at expense of capital in plant and time of operation. The latter is rendered inconsiderable by increase of plant, which makes greater capacity possible. This reduces the cost of labor, which is not idle.

♣♣♣♣

HERBERT LANG says the use of too light and fragile a fuel, in copper smelting, which is consumed high up in the furnace, will in every case give rise to a cooling of the hearth and the formation of incrustations, which defeat the intentions of the smelter. Then is required the application of greater heat to rectify the disturbance. This may be done by increasing the percentage of fuel, more particularly of coke.

♣♣♣♣

CRUSHING ROLLS of given size are supposed to have a definite capacity for crushing ores to a stated size; but to secure this capacity the rolls must be in charge of an experienced operator. The most important factor is the speed of revolution. There is much theoretical data on the speed of rolls and their work on the same material at different speeds; but experience shows some of the conclusions to be at fault. The capacity of wet crushing rolls is greater than dry crushing. The proper speed for rolls of ordinary size (24-inch diameter) is ninety revolutions per minute to crush coarse—to ¾-inch mesh—and 100 to 160 for finer crushing. Rolls of larger diameter should be run somewhat slower, so as to give the rolls about the same peripheral speed, which should be for coarse crushing about 565 feet per minute and for fine crushing from 650 to 1000 feet per minute.

♣♣♣♣

IT is needless to throw away old boiler tubes, for in most cases they are sufficiently good, if the ends be cut off, to rethread and use for air or water pipe where the pressure is not too high—say, 100 pounds per square inch. Much of the scrap iron and waste usually seen about mines can be utilized in some way if proper care be given to it. The "graveyard," as such a dump is called, often has within it hundreds, if not thousands, of dollars worth of good material, such as axles, iron and steel plates, old cars and a great variety of odds and ends cast temporarily aside and often forgotten.

♣♣♣♣

ANEROID barometers may be used in measuring the depth of mine workings, if a number of trips are made and the readings taken both going down and coming up. The average of the readings on several trips will give approximately the depth of the workings, or the distance between levels. When using the barometer in this manner the trips should be made without stoppages between the points where the distance is desired. Where the mine workings extend below the level of the sea a special instrument should be used to measure these minus elevations. Barometers are manufactured which will measure to 3000 feet below the level of the sea and read to 1 foot.

♣♣♣♣

THE California Code of Civil Procedure, Sec. 1192, says: "Every building or other improvement * * * * constructed upon any lands with the knowledge of the owner, or the person having or claiming any interest therein, shall be held to have been constructed at the instance of such owner, or person having or claiming any interest therein, and the interest claimed or owned shall be subject to any lien filed in accordance with the provisions of this character, unless such owner or person having or claiming an interest therein, shall, within three days after he shall have obtained knowledge of the construction, alteration or repair, or the intended construction, alteration or repair, give notice that he will not be responsible for the same by posting a notice in writing to that effect, in some conspicuous place upon said land, or upon the building, or other improvement situated thereon."

♣♣♣♣

SOME engineers think the size of hoisting ropes generally used in mines is unnecessarily large, and that smaller ropes would answer as well. For instance it is claimed that a rope of ⅞ inch diameter has a breaking strain of 50,000 pounds, while a rope of 1 inch diameter, costing 70% more, has a breaking strain of 88,000 pounds, and that under ordinary conditions the weight raised in mine skips, etc., not over 1500 feet in depth, does not usually exceed five tons, including rope, skip and load, which is a factor of 5 for safety. The smaller rope, moreover, admits the employment of smaller sheaves and drums, being 3½ feet diameter for the ⅞ inch rope and 4½ feet for the inch rope. The argument is not unreasonable, but the factor for safety should never be lower than 5, and a higher factor is preferable. It is not the usual practice, however, to raise 5-ton loads with ⅞-inch ropes. Ordinarily the skips do not weigh above one ton with a load of two tons, and in such cases the ⅞-inch rope is heavy enough for the work.

♣♣♣♣

THE amount of air consumed by a machine drill varies greatly. Large machines use much more than small ones, and the speed with which they are operated is also an important factor. There is usually more or less unavoidable leakage on the air line, and also at the cocks, all of which must be compensated for by the compressor. It has been theoretically calculated that a drill uses about 100 cubic feet of free air per minute, but some use more and others less than this amount. In figuring the consumption of air by the drills, the compressor must be taken into consideration, for some compressors have a much higher efficiency than others. Small air compressors are not nearly so efficient and economical comparatively as larger compressors. A small compressor taking 300 cubic feet of air per minute will not run more than two drills, while one having a capacity of 3000 cubic feet of air per minute will keep thirty or more drills supplied with air. This is due to relatively greater losses from leakage and friction in the smaller plant.

♣♣♣♣

GOLD may be precipitated from the terchloride solution by means of copper sulphide, the gold going down in metallic form. For ordinary conditions iron sulphate solution is as good a precipitant as can be found. It is easily made, inexpensive, and its application is simple. Hydrogen sulphide (H_2S) is also an excellent precipitant, but precipitates the gold as sulphide (it also precipitates copper, which is often present in the solution), while the $FeSO_4$ precipitates metallic gold. The sulphide precipitate settles more quickly than the metallic gold. Hydrogen sulphide requires considerable apparatus for its manufacture and application, and the ferrous sulphate solution requires neither. It may be kept in a wooden tank having no metal parts or nails. The tank is made of carefully planed lumber, and is bound together by ties of wood, tenons and mortises fitting nicely, the whole being tightened and kept tight by means of wedges. Generally there is no machinery whatever in a vat chlorination works where the Plattner process is in use. Where the material to be treated can be quickly gassed, and leached, this old-time process is superior to any other.

♣♣♣♣

PITCHBLENDE is an ore of uranium and pitchstone is a volcanic glass. The two terms are not infrequently confused. Other instances of this confusing similarity of names is found in chlorite (a magnesium silicate) and chloride (a union of chlorine, with a base); cyanide (a combination of cyanogen with an alkali), kyanite (an aluminous silicate) and syenite (a rock, composed of orthoclase and hornblende); lazulite (an aluminous phosphate) and lazurite (a sodium-aluminum silicate); alaskite (a siliceous aplite) and alaskaite (an argentiferous lead-bismuth sulphide); argentite is silver sulphide (silver glance) and argentine is lamellar calcite, having a pearly luster; chrysotile is a fibrous, silky serpentine, and chrysolite is olivine; chalcodite is a micaceous iron silicate, incrusting some iron ores, and chalcocite is copper sulphide (copper glance); dioptase is a copper ore and diopside is calcium-magnesium pyroxene. Many more examples might be added, but they are not necessary to show how confusing these names of minerals often are.

♣♣♣♣

THE discoloration of the mill plates may not be due to the ore at all, if it contains only iron sulphide and gold in a quartz gangue. Sometimes the spots on mill plates are due to the water used in the batteries and not to the ore. An ore may give no particular trouble in amalgamation, the percentage of saving being so high as to entitle it to be considered a free-milling ore, but the water from the mine may contain sufficient arsenic or some other mineral in solution to give a great deal of trouble to the mill man. An ore occurring on Osborne hill, Nevada county, Cal., was found very difficult to treat by the ordinary mill process, at the company's mill near the mine, and several tons were sent to a mill in another part of the district, and a high saving was made by the ordinary methods of amalgamation and concentration. This led to an investigation, and it was learned that the water from the mine had been used in the test of the company's mill, but that ditch water from the mountain snows and springs were used at the other mill. This experience proved that ore may be free milling while the mine water is detrimental to amalgamation.

♣♣♣♣

THE grade usually adopted for their sluices by placer miners is about 6 to 6½ inches to the 12-foot box, regardless of the width of the sluice. Where there is much clay the grade is often increased to 8 or 9 inches. The miner should experiment with the grade of his boxes, which should be suited to the material. If the grade be too heavy, not only will the greater amount of debris be carried out, but also often some gold. Light gravel can be more readily moved than that in which occurs abundance of iron and heavy basic rocks. It is best not to use too much water, as it has a tendency to pack the sand tightly in the riffles, allowing the gold to pass over and escape. Where there is a large amount of cobbles, the quantity of water should be sufficient to cover the largest of these that are shoveled into the sluice box. If only light grade is obtainable for the boxes, a greater amount of water is admissible, and vice versa, a heavy grade may be used where the water supply is scant. Twenty miners' inches (30 cubic feet per minute) is generally considered a sluice head under ordinary conditions, but, as indicated above, this amount varies with the change in conditions of grade and character of gravel.

♣♣♣♣

A LACCOLITH is a mass of igneous rock thrust upward into sedimentary beds, the force of the intrusion raising the beds in the form of a flattened dome. Usually the beds are split at several of their planes of sedimentation and the molten magma is thrust into these opened spaces, forming sills or sheets of injected rock. The first laccoliths to be described extensively were those of the Henry mountains, in southern Utah, by G. K. Gilbert. Laccoliths are not of uncommon occurrence; but much geological importance can be attached to them generally, as they are very often associated with valuable ore deposits. The ore deposits of Leadville, Colo., are directly associated with laccolithic intrusions; so also are those of Aspen and several other Colorado mining districts. Eureka, Nev., affords another example, and all of the ore deposits in the Cambrian and Carboniferous beds in the northern Black Hills of South Dakota occur in association with laccoliths. Other intrusive masses are variously known as stocks, dikes, plugs, etc. A dike is an elongated mass of igneous rock thrust into any kind of rock which has a dip nearer the vertical than horizontal. The dike may conform to the dip of the strata or may cut across them. It may vary from less than 1 inch to over 1000 feet or more in width; but its length must greatly exceed its width, or it will be known as a plug or stock. Where an igneous mass is intruded into sedimentary rocks and lies conformable to them, but is subsequently lifted by some force, the intruded mass is still a sill, as it would be called had it remained horizontal. A stock is a mass of irregular form, but approximately circular, as distinguished from the elongated intrusion or dike.

The Machine Drill in Mining.*

Written for the MINING AND SCIENTIFIC PRESS.

No one thing has contributed more largely to the reduction of mining costs than the machine drill. After centuries of mining by primitive methods, when the only tools were of wood and stone, iron, and finally steel, was introduced into mining practice, and each in its time at once raised the standard of measure of the miners' capacity to bore into the mountain side, or to sink far below the surface. The barbarous method of firing a rock face, and then dashing cold water upon it, to cause disintegration of the rock, and the final beating of the shattered rock with stone hammers has long since been a thing of the past, and the hammer, drill and pick have succeeded the ancient methods, but the advent of the machine drill marked the beginning of a new era, almost as important as the introduction of steel in mining.

Machine drills were first made and used in the United States, the first machine being introduced in 1838. In that year J. M. and John N. Singer made some experiments with a machine drill in the Illinois and Michigan canal, near Chicago. The drill was patented the following year, and a number of machines, made under this patent, were used on that work for about 3 years, so that the first machine drill to be made and actually operated in the world was the Singer. Other machines of this make were used on various large rock excavations in the Eastern and Middle United States.

From this date forward numerous types of machine drills made their appearance. One of the first and most notable departures from the form of the Singer drill was in the machine made by Couch & Fowle, who produced a steam-operated drill in which the drill bar passed through the piston, and which was alternately drawn backward and thrown forward against the rock. This machine was not a success, but it was one of the important steps toward the successful machine drill of the day. Messrs. Couch & Fowle did not agree upon what each considered the proper construction of a machine drill, and from the date of the failure of their machine each worked along the line of his own ideas. One thought the hollow piston drill the proper form of machine, the other clung to the idea of a drill solidly fixed to the reciprocating piston of the machine. Fowle made a number of machines, but none of them was a success, as compared with modern machines.

In the work of driving the Mont Cenis tunnel under the Alps and connecting France and Italy, compressed air was first introduced in the operation of a machine drill, which was constructed after the ideas of Fowle, but on somewhat different lines.

When the Hoosac tunnel in Massachusetts was under construction strenuous efforts were made to produce a machine drill which would hasten and cheapen the work. The drill employed in the work at Mont Cenis was considered, but finally rejected as being unsuited to the work on the Hoosac. The patents of Couch were bought and endeavors made to produce a satisfactory machine having a hollow piston. The result was known as the Hanson drill. This drill is described as having a hollow piston through which the drill bar passed, and which moved backward and forward with the piston. It was fitted with a valve motion similar to that of a steam engine. The rotation of the drill was accomplished by means of a ratchet and pawl, worked by a spiral device in the shell of the machine. The machine was very complex and contained 120 pieces. Fully assembled it weighed nearly 600 pounds. This machine worked "after a fashion," but was far from satisfactory.

The next important improvement came in the creation known as the Brooks, Burleigh & Gates machine. This machine also had a hollow piston, the drill bar being held in place by a threaded arrangement. The drill had the reciprocal motion of the piston. The feed was controlled by means of a nut on the end of the piston rod secured by a union or coupling device, which was screwed on the piston rod. One remarkable feature of this drill was that the area back of the piston was greater than that in front of it, so that the forward stroke was much more forcible than the back stroke. In this machine the piston head had a diameter of 4⅝ inches, and the diameter of the piston rod was 4 inches at the large end and 2¼ inches at the small end, the areas being 12.87 and 4.23 square inches respectively, with a difference in area of 8.64 square inches. The pressure at the forward end was not removed, as the pressure was applied at the rearward end, and the force of the blow was represented by the difference in area pressure. The machine worked automatically, and it ran usually until something broke or became disarranged, when it had to be taken apart. As the material from which the machines were made was not of the best, repairs were needed frequently.

The device ready to run weighed 240 pounds and cost $400. It operated at 200 strokes per minute. One of these machines performed the unusual feat (at that time) of running five days without breaking down. A two days' run without mishap was considered extraordinary. About forty of these machines were used on the Hoosac tunnel work at one time, but it required a procession of workmen to carry away broken drills and parts of the machine and to replace them with others. The average life of this machine is stated to have been about eighty hours. The machine was finally abandoned as too expensive and altogether unsatisfactory.

The next machine to claim attention was the Burleigh. This machine, designed by Chas. Burleigh, was after the Fowle idea, the maker buying the Fowle patents. In it the idea of the hollow piston was rejected and the Fowle scheme of a drill attached directly to the piston head was substituted. The machine was greatly simplified, the number of parts reduced, and the best material obtainable was put into it. So satisfactory did this machine prove upon trial that for years—from about 1867—the Burleigh was the principal rock drill in America, and so familiar did the name "Burleigh" become that it clings to the machine drill of to-day, and it is no uncommon thing to hear any kind of a machine percussion drill referred to as a "Burleigh." The old Burleigh machine still embodied some of the original ideas, which have long since been abandoned in machine drill construction.

The machine drill has been further improved from time to time, and there are now numerous makes of machine on the market, all of which are good, and it may be said of this class of mining machinery, as of some others, that it is difficult to say which is the best. If the miner—the man behind the machine—is appealed to for an opinion, he will invariably speak in favor of the machine with which he is most familiar, and which he has found, by practice, to give him satisfaction. The next man, while perhaps not decrying the merits of the machine favored by the first, will speak of his pet machine in terms as strong as the other. The fact is that all machine drills now on the market are good machines, for the simple reason that a poor machine cannot find ready sale, or use, by practical men who know what a good machine should be. There is possibly more difference in the ideas of miners as to the proper size of machine to use than in the make of machine itself; but here, again, comes the personal equation. Undoubtedly there is a place for the machines of small piston area, as well as for those of large area. And if this be true, then there must also be proper places for machines of intermediate area.

There are those who believe that hand work is superior to machine drill work. In driving tunnels, in stoping large ore bodies and in sinking in very hard ground the machine drill is superior to hand work, and machine work per foot or ton is generally far less expensive than hand work. Of course, there is not much advantage to be gained in using machine drills in soft ground, or even in that that is fairly easy, for under such circumstances there is likely to be much time lost.

Where ground is not very hard, the smaller machines will generally give better satisfaction, for they are cheaper in first cost, require less air to operate, and, as the drill bits are generally smaller, should, if properly handled, cut as fast as the large machines. Moreover, drill holes of large diameter are not required in "easy" ground, as sufficient powder can be tamped into a hole of small bore to break the rock.

In stoping small veins, where the walls are not firm and much waste is consequently made, the matter requires good judgment. If the ore and walls are both soft and break down together under machine drill work, it would probably be advisable to stope by hand; but this need not influence the use of the drill in development work, in crosscutting, etc. If the ore is firm and the walls soft, it may be the better plan to stope with small machines, and, if the ores does not make too much fines, the fine waste can be screened out by passing the broken rock over a grizzly or through a trommel. If both walls and ore are hard, the machine drill should prove more economical than hand work. In large mines there are levels which justify the use of hand drilling, and other usually lower levels where the machines can be used to better advantage.

There are many engineers who do not agree upon the general use of machines in shaft sinking, the advocates of the machine claiming that the speed of sinking can be increased by using machines and, therefore, are advisable. Those of contrary opinion usually admit that the rate of sinking can be increased by employing machines, but that it is at the same time more expensive than hand sinking. Here again it is almost entirely a matter for the exercise of good judgment. In most cases the use of machines in shaft sinking will be found to possess advantages over hand sinking.

The relative advisability or advantage of hand and machine sinking can not always be determined from a consideration of the actual cost of labor performed and supplies used per foot of shaft sunk. It is acknowledged that in good hands machines make greater speed than when the work is done by hand. It is often the case that large capital is invested in surface plant and in the purchase of the property itself, while production can not be commenced until the shaft is sunk to the ore body and several levels opened up in order that extraction may be carried on upon a scale commensurate with the extent of the property and capital invested. If this outlay of capital be no more than half a million dollars, and not infrequently it is more, the interest on this sum would be figured at $25,000, at least, per annum, which, when shaft sinking was progressing at the rate of 100 feet per month by hand work, would mean an interest charge of $20 per foot. In such a case it would without doubt be less expensive to use machines to put the shaft down in as short a time as possible.

Under ordinary conditions the cost per foot for drilling by hand will range from 30 to 75 cents, while with machines it is from 5 to 25 cents, averaging probably 15 cents (including every expense incident to the work).

In the operation of a machine drill one of the most important items of expense is that of repairs, and the extent to which this feature of the expense account is swelled depends in a large degree upon the drill runner—on his ability, carefulness and experience and in no small degree on his temper. If he is painstaking and understands that his machine is an engine and not a mere mass of metal, he will run up a smaller bill for repairs than the careless, irascible fellow who thinks the proper thing to do, when the machine fails to operate to suit him, is to strike it viciously with a sledge or heavy wrench, or to permit his assistant to do so. In the first place fitchered holes are largely the result of careless starting of the hole, or the machine is not clamped sufficiently tight upon the bar. Often a fitchered drill will work all right if the machine runner loosens the clamp bolts a little, so as to shift the machine slightly, and loosen the drill. All of these things are learned by experience.

When about to start to drill a round of holes, the machine runner should choose a position for his bar which will admit of drilling as many holes in the proper places as possible with the one "set up," for this requires time. The footing and overhead rock, (or the rock sides) should be as firm as possible, for if they are not, there will be danger of the machine loosening the ground by its heavy vibrations. If the space from head to foot is very much greater than the length of the bar, a broad, substantial crib of timbers should be constructed for the foot and a heavy block put in over head, and the bar tightly screwed up, when additional security is gained by driving wedges between the head block and the roof —or the side walls, as the case may be. For the safety of the miners, and for the accomplishment of good work, the bar must be so firmly fixed that there is no danger whatever of its shifting after drilling has commenced.

The next thing is to mount the drill on the bar, (either horizontal or upright). Many miners clamp the machine directly on the bar. This holds the machine rigidly in place, but a little more latitude to operations is afforded by the use of the projecting arm supplied by the drill manufacturers, and which is securely clamped to the bar. The arm is mostly used when the bar is set upright. Bars are fitted with single or double screws at the foot, for the purpose of tightening the bar. The double screw is preferable where the bar is long. Bars are made of various lengths, to be suited to the mine workings. They range from 5 feet or less to a length of 9 feet. A bar of more than 9 feet is subjected to too much vibration for satisfactory work, and if the distance between rock faces exceeds this greatly, a crib should be built and a shorter bar used.

In shaft sinking horizontal bars are used—usually the single screw. In drifting a similar bar is employed, but most miners prefer the double screw in large tunnel work, though in railroad tunnels, quarries and similar large rock excavations, where much benching is done, the tripod is commonly substituted for the bar. The machine may be operated in any position, above or under the bar—the position is not so material as absolute rigidity, and this is imperative, for if the machine shifts after getting well started the hole may be lost.

In drifting it is not uncommon to place the bar in a horizontal position near the roof above the dirt broken down from the last round of holes. This permits the shovelers to remove a large portion of the broken rock while the upper holes of the next round are being put in. When the broken rock is all out, the bar may be shifted to the bottom and the lower holes drilled. This is only advisable where work on the drift is being rushed. It is more satisfactory to have two places on a level where the machine may be used, so that while the muckers are engaged in one face the drillers may work in the other. To get value out of the machine it should be kept employed, as well as the men who manipulate it. Machine miners should not be required to muck dirt. It is cheaper to hire unskilled laborers for this work, as the machine man usually receives from 25% to 50% more pay than the mucker.

The rate of progress is something that is carefully watched by the management, and, as this is the most essential thing, the conditions under which the machine is run should be made as favorable as the situation will admit. If the working place is wet, the miners and the machine should be protected from falling water as much as possible. Good air should be supplied in addition to that coming from the exhaust of the machine, for the exhaust air is not always pure, by any means, and is occasionally poisonous, being charged with carbon dioxide, due to combustion of oil and dust in the cylinders of the compressor. Conveniences for mucking should be provided, such as laying a shoveling floor before blasting, and every-

*See illustration front page.

thing reasonable done to advance the progress of the work by making the labor as easy for the workmen as the circumstances will allow.

Another important factor in the economy of operations is in the drill bits. Nothing but good steel should be provided and the bits should be carefully and thoroughly made, and gauged so that there will be no difficulty about the several sizes following each other. In very long holes—over 7 feet—it is not bad practice to substitute chisel bits for the ordinary cross (+) bit generally used in machines. Where the ground is not too badly fissured they will be found an advantage in finishing a long hole. The temper of the drills is of equal importance, and this is a matter for the drill sharpener to decide. All rock does not work equally well with the same temper. A drill tempered bright straw color may be too hard for very hard rock, the edges of the bits, and sometimes good-sized pieces of steel chipping off, giving much trouble in proceeding with the hole. A slightly darker color may be found to work to better advantage, even if the drills are more quickly dulled. There will be less loss of steel and less loss of time. The tempering of machine drills is a matter which requires experience and good judgment. The drills should be made as hard as the material in which they are working will admit without chipping. If the steel in heating is burned, it is economy to cut off the burned end at once, as it will only give trouble in the mine. The drill bits should be so forged that immediately back of the cutting edge they have a slope backward toward the shank of the drill—this to avoid the drill sticking in the hole. There is a great difference in the rate of progress between drills that are properly forged and tempered and those that are not. Another thing, the drill sharpener should see to it that every drill that leaves his hands is perfectly straight (a condition in which they are not always returned from the mine). If a shank be slightly bent it causes the bit to rotate in a small circle, cutting a larger hole than necessary, and consequently making slower progress than it should, and, moreover, there is greater danger of getting the drill stuck in the hole when it is well advanced. Sometimes the bit is bent by the heavy blows of the chuck tender, when the same thing is likely to occur. If a hole that has been drilled over 4 feet gives much trouble, and a smaller chisel bit cannot advance it, it had better be discontinued and loaded with the remainder of the series, and if the drill cannot be withdrawn with a reasonable amount of pounding and other effort, the drill had better be left in the hole, to be recovered after the round is fired, for it is an easy matter to lose from thirty minutes to an hour in the endeavor to recover a tightly fitchered drill. This means the time of two men, usually, and costs more to bother with than the cutting of a new hole.

The machine drill sharpener is a new and very important factor in the use of the machine drill in mines and has done much toward cheapening the cost of work with machines. A large amount of work can be accomplished with them and there is more uniformity in the shape of bits, as well as in the gauges, so that there is no trouble in the bits following.

The Mint and the Miner.

As the information published in the issue of June 24th last under this caption resulted in some correspondence, and as there are those apparently who do not fully understand the rules of the mint at San Francisco concerning the purchase of bullion, the following from Superintendent Frank A. Leach of that mint in response to an inquiry will be of further interest in the matter:

TO THE EDITOR:—Your letter of the 3d inst. relative to the character of bullion subject to refusal for deposit in the United States Mint received. I think your correspondent is laboring under a misapprehension of facts. Possibly the paragraph quoted is susceptible to the inference made by him, and if so it is inconsistent with paragraph 2 of section 1, article 1 of the "General Instructions and Regulations of the United States Mints and Assay Offices," which says:

"If the bullion appears to be of less value than $100, or so base as to be unsuitable for the operations of the mint, it may be legally refused."

From which you will observe that the matter of rejecting bullion is discretionary. We do accept very low-grade bullion when all the base is copper, and we reject bullion of much higher fineness when the base is composed of antimony, zinc, bismuth, arsenic or iron. Then again we are more particular as to the amount of troublesome base in a large deposit than in a very small one. Then again we are not so particular in discriminating against base deposits if we only have a small amount of that character of bullion on hand, but if, on the other hand, there should be quite a large run of base bullion, we would be inclined to look after the character with more care. We endeavor to accept all offerings of bullion brought to the mint, so as to put the depositors to as little trouble as possible, but there are times when it is against the interest of the mint to accept further amounts of exceedingly base deposit. You can readily understand why this is so when we recall to you that in our parting work the process will tolerate a certain percentage of base. Now the greater amount of high-grade bullion we have to refine, the greater amount of base bullion we can receive to go along with the high grade.

However, the rejection I think your correspondent refers to was for a different reason. You are probably aware that we are not allowed to purchase silver bullion—only such silver as may be associated with the gold in gold bullion. Gold bullion is designated as such only when there is a greater amount of gold than silver, and silver bullion is designated as such when the silver predominates. Thus, a bar might be a little under 500 fine gold, and would still be classed as silver bullion if the remaining parts were all silver, though the gold values were many times more than the silver.

FRANK A. LEACH, Superintendent.

San Francisco, July 5.

Ore Deposits of the Cœur d'Alene, Idaho.

NUMBER II.

Written by F. L. RANSOME.

HISTORY OF MINING DEVELOPMENT.—The story of the opening of the Cœur d'Alene region to mining enterprise goes back to the year 1842, when a mission was established by the Jesuits in the beautiful valley of the St. Joseph river, a navigable stream which empties into the head of Cœur d'Alene lake about 5 miles south of the embouchure of the Cœur d'Alene river. In 1846, however, the mission was moved to its present site on the latter stream, about 25 miles from the lake, and for many years Father J. Joset and missionaries associated with him were the only white inhabitants in this whole region. The Cœur d'Alene Indians, about 300 in number, lived chiefly in the vicinity of the mission.

In 1854 Lieutenant John Mullan, acting under instructions from the War Department, began explorations for a wagon road over the Cœur d'Alene mountains to connect Fort Benton with Fort Walla Walla. These preparations aroused the hostility of the Indians, who, after defeating a small force of regular troops, were subjugated in 1858. In the following year work on the proposed road was begun under a congressional appropriation, and the task seems to have been finished in 1861. The new road crossed from the mouth of the St. Joseph river to the mission on the Cœur d'Alene river. Thence it followed the main stream and south fork to a point about 3 miles east of the present town of Mullan. Here it turned south, crossed the divide through the Sohon or St. Regis Pass, and continued down the St. Regis de Borgia river, following the route later taken by the railroad to Missoula.

Roughly constructed as it was, this road, now familiarly known as the "Old Mullan road," was for many years the only line of travel into the region to whose early development it substantially contributed. It traversed what afterwards proved to be the most productive part of the district, but the discovery of the lead-silver deposits was reserved for a later date.

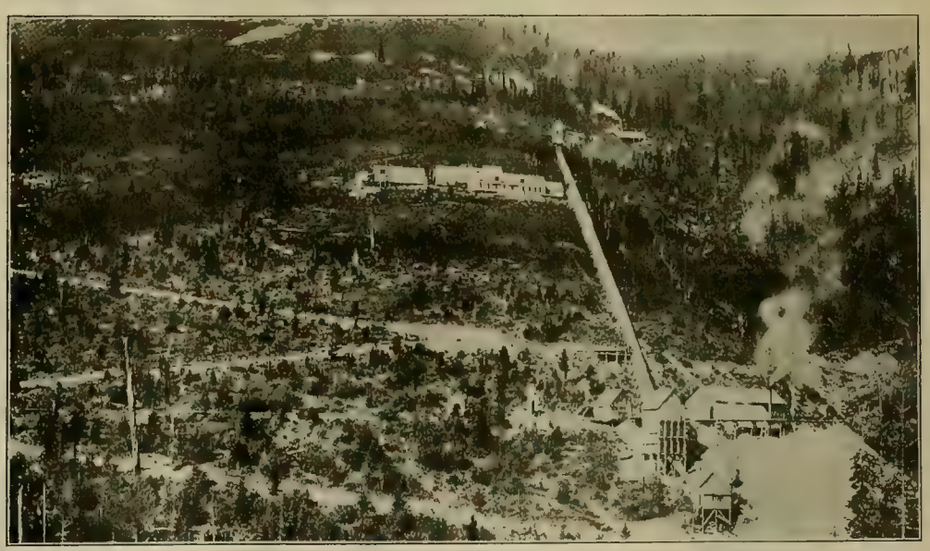
The first prospecting in the region appears to have been by Thomas Irwin, who in 1878 located a quartz claim near the Mullan road, apparently on Elk creek. In the summer of 1879 a party, including A. J. Prichard, moving northward from the Mullan road over the Evolution trail, discovered Prichard creek. In 1882 Gellett, another member of the party, found placer gold and located a claim on Prichard creek. The first quartz claim on Prichard creek was the Paymaster, near Littlefield, located by Patrick Flynn on September 21, 1883.

The discoveries of Prichard and Gillett were followed by a rush of prospectors to the North Fork early in 1884, and in May, Eagle City, at the junction of Eagle and Prichard creeks, had become a bustling town connected by trail and telegraph with Belknap, 32 miles away, on the Northern Pacific Railway. It was soon found, however, that the richest placers lay higher up Prichard creek, particularly in Dream, Buckskin and Alder gulches, and the center of population soon shifted to the new town of Murray.

Although the chief excitement at this time centered in the rich gold placers near Murray, the lead-silver veins of the South Fork were beginning to attract attention. In 1884 Col. N. R. Wallace had a cabin and store in the dense grove of cedars that covered the future site of the town now bearing his name. His settlement was then known as Placer Center. At the same time W. B. Heyburn began work on the Polaris mine, in Polaris gulch. The Tiger claim, on Canyon creek, was also located in 1884 by John Carton and Almeda Seymour, who bonded it to John M. Burke. In 1885 the Tiger mine, in spite of its comparatively inaccessible position, had been opened by three tunnels and had about 3000 tons of lead-silver ore on the dump. Other mines located in 1884 were the Gold Hunter, Morning and You Like, near Mullan, and the Black Bear, San Francisco and Gem of the Mountains (now comprised in the Helena-Frisco mine), near Gem.

The discovery of the Bunker Hill mine by Philip O'Rourke and N. S. Kellogg in 1885, and of the Sullivan mine by C. Sullivan and J. Goetz, and the evident existence of large bodies of rich ore in the Tiger, Poorman, Granite, San Francisco, Morning and other mines, removed all doubts of the future importance of the South Fork mines. The opening of the year 1886 was marked by a decided rush from the outside and from the waning placers of Murray into this new field, particularly to the settlements of Milo and Kentucky, now parts of Wardner and Kellogg. Tri-weekly stages ran from Mission to Wardner.

In 1886 ore from the Bunker Hill and Sullivan mines was hauled by wagons to Mission, carried by boat to the outlet of the lake and thence shipped to Helena, Mont. The ore from Last Chance, Tyler and Sierra Nevada mines was treated in a new smelter at Milo. This early attempt at local smelting was soon abandoned.



The Hercules Mine, Near Burke, Idaho.

In the following year a narrow gauge railroad was completed by the Cœur d'Alene Railway & Navigation Co. from Mission to Wardner Junction, at the mouth of Milo creek. Wardner had now become a town of 1500 people, while the population of Murray had fallen to about 1000. There were about 500 inhabitants at Wallace, and Burke and Mullan were growing settlements. Probably 100,000 tons of ore were piled on the dumps of the Canyon creek mines awaiting means of transportation. The Oregon Railway & Navigation Co. and the Northern Pacific Railway were both striving at this time to secure entrance to the district.

In April, 1887, the Bunker Hill and Sullivan mines were sold to S. G. Reed, and in August the Bunker Hill & Sullivan Mining & Concentrating Co. was organized. The Poorman, Granite and Morning mines were also sold at about this time. The completion of the narrow gauge railroad to Burke in this year enabled the Canyon creek mines to ship their ore. Probably over 50,000 tons of lead-silver ore was mined in 1887, the principal producers being the Tiger, Bunker Hill & Sullivan, Tyler and Stemwinder, Last Chance, Sierra Nevada, Poorman and Granite. The Mammoth and Standard veins were as yet merely good prospects.

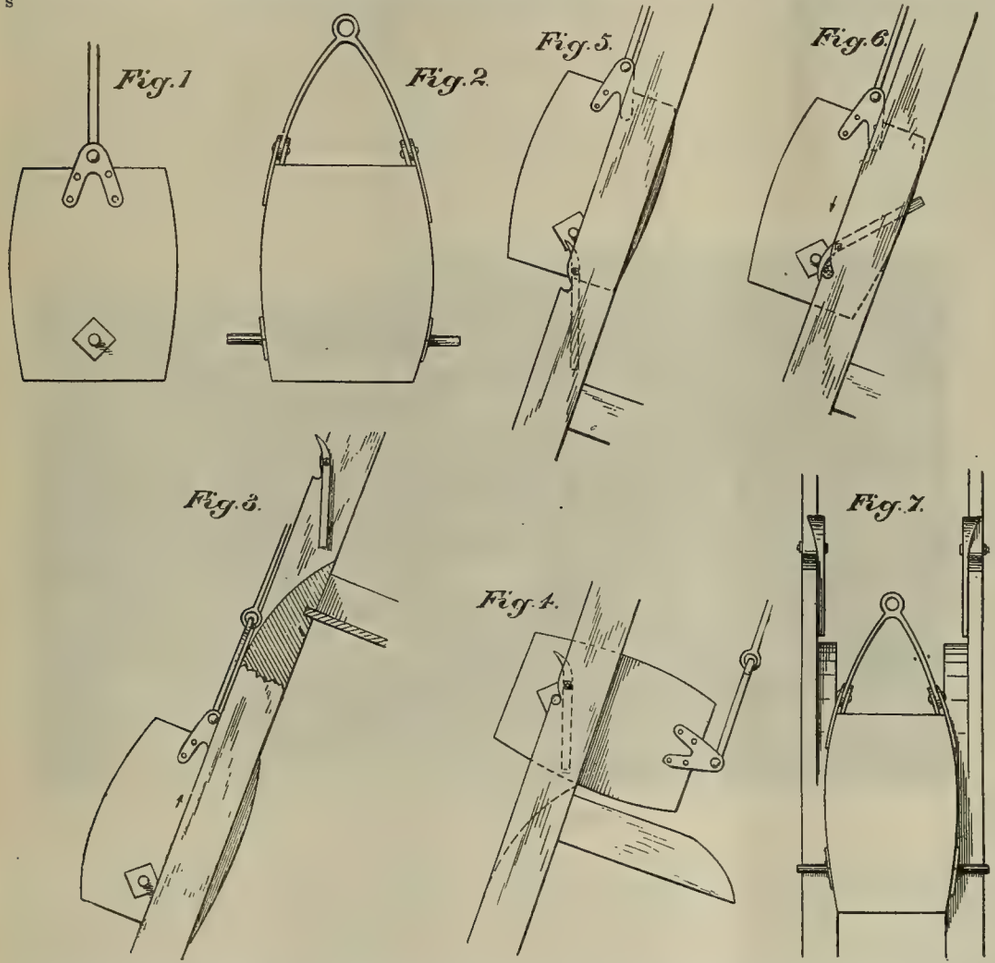
The principal events in 1890 were the completion into the district of the tracks of the Northern Pacific Railway and Oregon Railway & Navigation Co., the partial destruction by fire of Wallace and Wardner, and the first shipment of rich ore from the Mammoth mine. The old narrow gauge line was absorbed by the Oregon Railway & Navigation Co. and its tracks were replaced by those of standard gauge. Most of the larger mines were by this time equipped with concentrating mills.

(TO BE CONTINUED.)

Automatic Bucket Dumping Devices.

The employment of automatic dumping skips has led to various more or less successful attempts to introduce automatic water and ore-dumping devices where buckets are used. These devices are used in both vertical and inclined shafts, and are various in form, some being simple in construction and operation and others more or less complicated. In a contrivance of this character simplicity of construction and ease in operation should not be sacrificed to elaborate design. Two of the automatic devices are here shown in a series of sketches. One is for application in inclined shafts, the other is for use at a vertical shaft.

Of the first a description is scarcely necessary, the several figures showing the method of operating. Figs. 1 and 2 show the form of bucket or kibble used in this instance, though a straight bucket would probably work as well. Buckets which are smaller top and bottom than at the middle, like the Cornish kibble here illustrated, or those which are crimped to maller diameter at the top, in place of a band riveted s



on to give strength to the bucket, frequently give trouble in dumping by the rock jamming in the mouth of the bucket. It will be noticed that heavy lugs are provided on this bucket and placed near the bottom. This lug does not touch the skids during the passage up the shaft.

Fig. 3 shows in the shaded portion where the inner side of the skids are cut away to allow the bucket to settle lower on the track. When being hoisted higher the lug drops into the notch provided for it, which should be of iron, and then, upon the rope being slacked, the bucket dumps automatically by gravity. The engineer hoists, the lug rises out of the notch, pushes the latch aside, and when the rope is slacked the bucket descends, the lug being carried over the notch by the latch, as shown in the sketch Fig. 6.

In Fig. 7 is seen the arrangement of inside skids, the latches and lugs. This device is simple of construction and if properly made operates as satisfactorily as any device used for this purpose in inclined shafts. This arrangement would not be satisfactory at a vertical shaft.

Fig. 8 shows an automatic dumping device at a vertical shaft. In this instance a bucket having straight sides with heavy chimes top and bottom is used. The lower chime extends 1 inch below the bottom of the bucket, which is concaved somewhat upward to give it additional strength. The bucket has no lugs and requires none. A door is constructed, hinged at one side of the shaft, which when closed will drop across the shaft at an angle of about 45°. This door is controlled by a rope which passes over a wheel to the engine house, where it is within easy reach of the engineer. A counterweight is attached to the rope, so that it may be readily handled. A vigorous pull on the rope causes the door to assume an upright position, when the bucket may be lowered into the shaft. When the bucket is hoisted above the top of the door, a jerk on the rope will cause the door to spring outward over the shaft and to drop upon the support on the opposite side. The bucket is then lowered. When sliding downward, the chime at the bottom catches upon an iron projection placed on the door and the bucket is overturned into a chute or bin.

Another arrangement, quite as good as this, if not better, is in a door which operates in the same manner as that described, but in which the door is provided with a slot about 3 inches wide. Beneath the bucket is a short rope or chain attached to the ring and having a block of wood, about 6x4x8 inches, secured to the end of the rope or chain. When the bucket has been raised above the door, a jerk on the rope in the engine house causes the door to drop across the shaft, the slot in the door straddling the short rope. When the cable is slacked the bucket slides down the door until the block is caught by the door, being unable to come through the slot. The bucket overturns and dumps its contents into the bin or chute. This latter has the advantage of dumping any shape of bucket and the additional advantage of permitting the door to be dropped across the shaft, if desired, when the bucket is below, the rope passing through the slot in the door.

THE PROSPECTOR.

The "gem" from Baker City, Or., is opal. It is very ordinary and without value. Opal to command a good price must be full of fire, of the green, blue, orange and red tints.

The black specimen from Baker City, Or., is clay containing a large amount of carbon which burns out on the application of high heat, leaving a whitish gray earthy mass which fuses slightly on the edges.

The rocks from Lamar, Colo., are: No. 1 (white with black spots), a friable sandstone in which the grains are all of quartz, some of which are angular with crystal faces, others rounded and water worn, and still others are sub-angular. The rock presents the appearance of having been originally cemented by some easily soluble material, probably calcium carbonate, but which has since been leached out. The black spots are apparently manganese and iron oxide. No. 2 is a fossiliferous limestone. The fossils are indistinct and can not be determined.

The Ore Deposits of Mount Lyell.*

Written by J. W. GREGORY.

THE FAHLBANDS.—The ore deposits of Mount Lyell consist of two types—(1) mineralized bands of schist, and (2) great lens-shaped masses of very pure sulphide ores. Bands of pyritiferous quartzite also occur in the conglomerate series, and may be regarded as of similar origin to the bands of mineralized schist; but only the latter contain sufficient ore to be of any economic importance.

The minerals which occur in the bands of mineralized schist are chiefly iron pyrites and fahlore, associated with copper pyrites and bornite. These minerals are in places loosely disseminated through the ordinary schist; elsewhere they occur in the siliceous schists, forming acid copper ores, and some bands of low-grade material that has hitherto only proved of value as a flux in smelting the pure pyritic ores of the great ore bodies.

The mineralized bands are widely spread through the schists of the Mount Lyell field. Their interest was recognized by Haber, who identified them as fahlbands, the most appropriate name for them. That the term is well applied to them may be seen by reference to any recent definition. Thus J. F. Kemp of Columbia University defines fahlbands as "belts of schists which are impregnated with sulphides, but not in sufficient amount in the locality where the name was first applied (Kongsberg, Norway) to be available for ores." The fahlbands of Mount Lyell are widely distributed through the schists, but occur especially along the course of the chief transverse

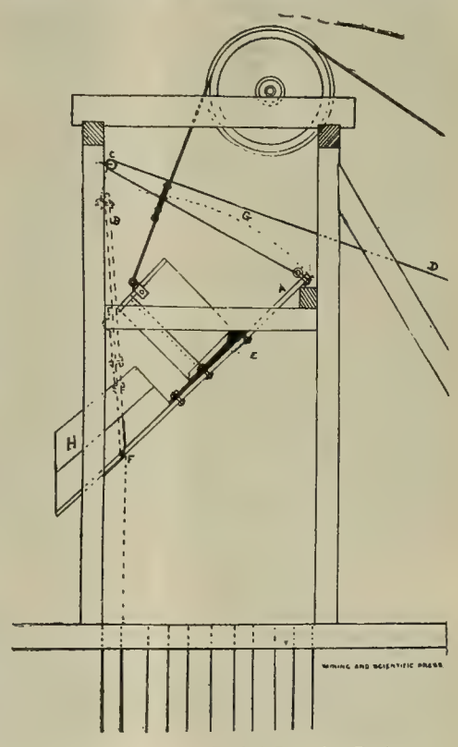


Fig. 8. Automatic Bucket Dumping Device.

faults. As examples may be quoted some bands of mineralized schist along the North Lyell road to the west of the North Lyell gap; there is a good representative in the ground held by the copper mines of Mount Lyell West, and near by, on the boundary between the lease of the same company and the West Lyell Extended, the strike of the rocks is extremely confused, probably owing to movements along the continuation of the fault, which runs along the southern scarp of the North Lyell spur. Another illustration of the fahlbands occurs south of the haulage, on the ridge overhanging the Gormanston road, where some works have been opened in mineralized schists, in the western end of the lease. The strike of the rocks immediately to the north of this band is extremely confused, probably owing to the westward continuation of the fault, which runs along the northern face of Mount Owen and on the southern bank of the Linda valley.

The foliation of the schists strikes N. 40° W. The ore is in bunches, which vary in thickness from 4 feet down to 1 foot. The bunches are about 6 feet in length, and they are separated from one another by several feet of barren country, composed of crushed and brecciated schist. The ore bunches were traced, during some prospecting work, 80 feet downward and 30 feet upward; they appear to have been a series of chimney-like shoots along a fault plane running parallel to the country rock. At the upper tunnel the rocks are the ordinary Lyell schist, separated by

*Abstract Trans. Aus. Ins. Min. Engrs.

bands of quartzitic schist, with a strike of N. 35° W. At the mouth of the tunnel is a mass of iron pyrites, separated from the schist by a fault which dips to the west.

The ore from these workings consists mainly of pyrites and fahlore; and the average of all the daily assays taken in the rise along the ore shoot was :

Copper, per cent	6 96
Silver, ounce per ton	0 36
Gold, ounce per ton	0 008

In the ore of further workings the copper averaged 6.02% and 7.34%. The ore is, therefore, for this district, high grade, but its small amount and erratic distribution deprive it of any economic value.

In the next lease to the south, on the hill slope above the Gormanston road, is a seam of barite in quartzose schist, the foliation of which trends N. 40° E. and dips to the northwest. The schists are traversed by thin lines of pyrites, resembling the pyritic "indicators" of Ballarat. In the same lease there is a large deposit of mineralized schist well exposed in a tunnel, going at 55° into the hill at right angles to the foliation of the schist. The schists here are very siliceous and contain abundant seams of quartz and lines of pyrites. At this point there were no bunches of ore or shoots as at the Reserve tunnel; but the schists are traversed by many seams and bands of pyrites. The tunnel was driven 100 feet in length, and according to Mr. Aaron White, the foreman in charge of the work, it did not pass half way through the pyritized rock, which can be traced on the surface for a greater thickness.

The tunnel of the Mount Lyell Reserve Co. on the left bank of Conglomerate creek, close to the stream, was begun at the outcrop of another fahlband. The tunnel was driven for more than 60 feet, through dark-green schists with a strike of N. 30° W. A thin band of ore was passed through at the mouth of the tunnel; but no more ore was found within it; and no effort was made to follow the deposit along the strike, probably from absence of any sign of its extension in that direction. The ore is said to have yielded 4% of copper.

The fahlbands, which are mere pyritized bands of schist, have so far proved of more scientific and historic interest than of economic importance. Their discovery in so many localities encouraged the hope that many great pyrites bodies existed in the district. They thus led to the belief that copper ores are deposited in a series of lodes running continuously north and south across the field. Hitherto the attempts to work these pyritized seams have been unprofitable; but there is a more important series of fahlbands, which have been successfully worked by the Mount Lyell Mining & Railway Co. as metal-bearing fluxes. The basic pyritic ores of the Mount Lyell mine require a siliceous flux, and the acid ores of the larger fahlbands serve this purpose and contribute their own copper contents at the same time.

THE SOUTH THARSIS MINE.—The South Tharsis mine is situated three-quarters of a mile to the north of the Mount Lyell mine, and one-quarter of a mile to the southwest of the North Lyell. It contains a band of pyritized schist, which was worked by an open cut, developed on three benches; and its subterranean extension has been explored by a diamond drill bore put down to the west of the outcrop. The mine was worked by a company in 1899, which began the open cut and erected concentrating works on the slope below the mine, on one of the tributaries of Glover creek. The process, however, was not a success, for the brittle copper pyrites was crushed to a slime and much of it was lost, while too much of the iron pyrites remained in the concentrates. The property of the company was acquired in 1900 by the Mount Lyell Mining & Railway Co., which could profitably smelt the material as a siliceous flux in conjunction with its own basic ores.

The metalliferous material is developed as a fahlband, and is well shown in the open cut. Its well-defined western wall trends north 25° west, and is parallel to the strike of the adjacent schists. The fahlband is continued below by a band which dips to the west at an angle of 1 in 2, and was pierced by a bore put down from a point in the hill slope at the level of 1482 feet above the sea. The geological relations of this body have been proved by a tunnel below the open cut, which has been driven eastward till it ended against the vertical fault face of the conglomerate, which is almost vertical, but has a slight dip to the west.

An underground extension of the Royal Tharsis ore body in the lease of the South Tharsis mine has been proved by a series of drives. The southeastern "hanging wall drive" followed the hanging wall of the fahlband for 146 feet, and proved the occurrence of the metal-bearing flux all along it; and the No. 4 crosscut from this drive passed through 65 feet of the metal-bearing schist, which is of a satisfactory grade for that thickness.

The southeastern hanging wall drive, No. 2, from the Royal Tharsis mine, explored a separate belt of mineralized schist, which is to the east of the main belt. This drive crosses the northern boundary of the South Tharsis lease, and crosses the strike of the metal-bearing schist obliquely for 197 feet.

The South Tharsis, to the end of September, 1902, yielded 49,287 tons, with an average assay value of copper, 1.64%; silver, 0.22 ounce, and gold, 0.022 ounce. The variations in the yield may be illustrated by the figures for the material worked for the half-years ending March 31, 1901, March 31, 1902, and Sept. 30,, 1902, in which the amounts yielded were, respectively, 8353 tons, 12,779 tons and 17,666 tons, giving an assay value of :

Copper, per cent	1.54	1.67	1.68
Silver, ounce	0.19	0.24	0.24
Gold, ounce	0.019	0.019	0.026

The average composition of the South Tharsis flux includes :

	Per Cent.
Silica	62 67
Iron	8 05
Alumina	12.17

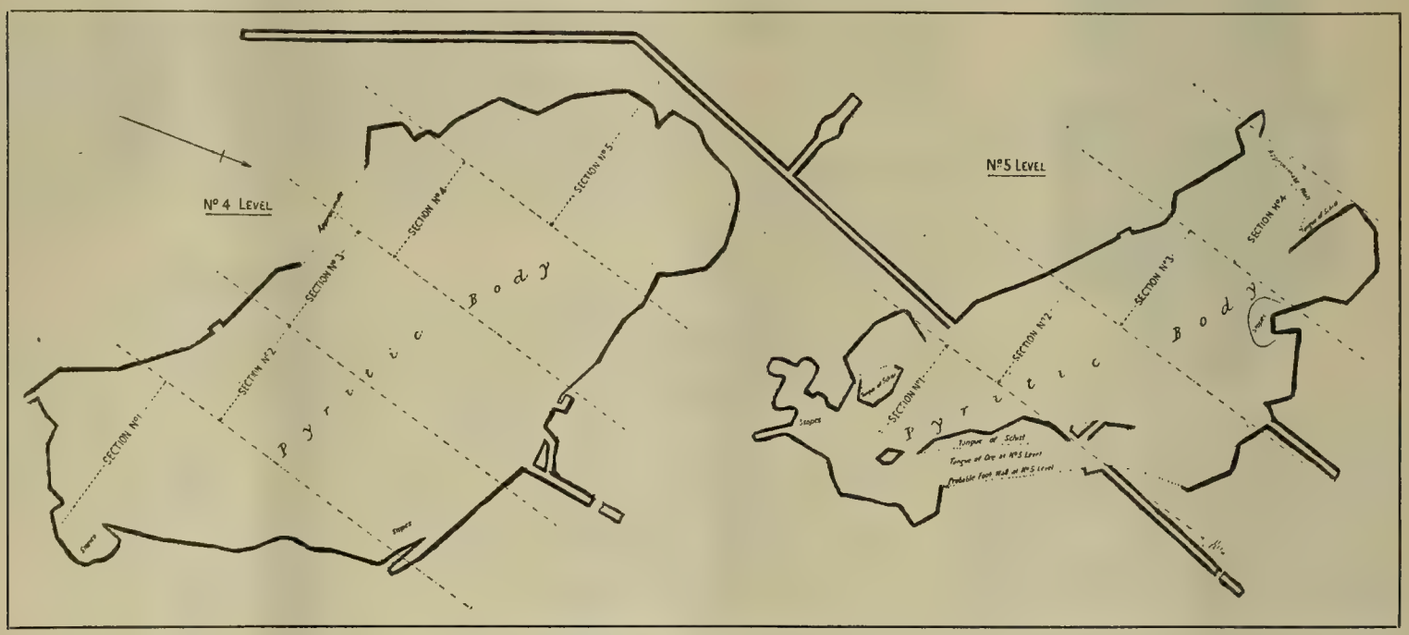
THE ROYAL THARSIS MINE.—The lease of the Royal Tharsis mine is immediately to the north of that of the South Tharsis, and contains an extension of the same belt of mineralized schist. As, however, the material has to be obtained by underground workings, it is more expensive to work than that of the South Tharsis mine. Therefore, though its grade is somewhat higher, it has been less worked. The property was acquired by the Mount Lyell Mining & Railway Co. early in 1901, and is developed by three underground levels.

The Royal Tharsis mine yields a siliceous flux of schist containing pyrites and chalcopyrite. The mine yielded up to September, 1902, a total of 2274 tons of ore, of an assay value of copper, 2 11%; silver, .24 ounce, and gold, 0.23 ounce. For the following half year before March 31, 1902, it yielded 1403 tons, with an assay value of copper, 2.04%; silver, .22 ounce, and gold, .021 ounce. For the following half year it yielded 871 tons, with an assay value of copper, 2.21%; silver, .27 ounce, and gold, .027 ounce. The average composition of the metal-bearing flux of the Royal Tharsis includes :

	Per Cent.
Silica	61 17
Iron	9.94
Alumina	10.44

THE LYELL THARSIS MINE.—The Lyell Tharsis mine lies in the lease adjacent to the North Lyell mine. The ore body extends into the North Lyell area, and is now being worked by the amalgamated company. The mine contains a body of siliceous ore, which is lenticular in shape, and was about 20 feet wide in the best part.

THE ORE MASSES IN THE MOUNT LYELL MINE.—The great masses of sulphide ores are the source of the wealth of the Mount Lyell field. There are two main ore bodies. The largest is that of the Mount Lyell Mining & Railway Co., known as the Big mine and as the Iron Blow. The mine is situated at the height of 1415 feet above sea level, on the eastern flank of the ridge of schists which connects the western end of Mount Lyell to Mount Owen, across the head of the Linda valley. It is situated to the south of the eastern end of the haulage, and to the north of the town of Gormanston. When first discovered most of the surface of the ore body was covered by a deposit of gravel and soil from 12 to 20 feet thick, and supporting a growth of button grass. In places, especially toward the northern end, the soil was very shallow and the water courses had cut down to the ore body, exposing the fresh, unoxidized pyrites. At the southern end of the ore body, between it and the country rocks, was a thick ironstone gossan and the hematite



Plan of Mount Lyell Mine, N. S. W., Showing Shape of Pyritic Ore Bodies.

of the iron blow. The gossan was composed mainly of silica, barite and iron oxide, which contained also 15 ounces of silver and 15 dwts. of gold. The pyrites had been decomposed, and all the copper and most of the iron removed by leaching. This deposit was long since removed, and all sign of the surface outcrop is now destoyed. The ore body trends northwest by west, and its length on the surface was 800 feet and its width 200 feet. It is worked by an open cut, by a series of nine terraces or benches. The present floor of the excavation, No. 4 bench, is 272 feet below the original top of the deposit. The ore has now all been removed above the four uppermost benches. The excavation at the end of 1901 was oval shaped, 800 feet long, 630 feet wide and 272 feet deep. Beneath the open cut is a series of underground works, including levels Nos. 5–8, by which some masses of rich ore have been mined, and the size of the ore mass determined at the successive levels; the further extension has been tested by diamond drill boring.

The chief facts as to the size and shape of the Mount Lyell ore mass have been definitely determined. It is irregularly boat shaped in form, consisting of an elliptical mass, which tapers gradually downward, and is then cut off below with a rounded base. Horizontal sections across the ore mass (see accompanying sketch) are irregularly elliptical, and the major axis of this ellipse at the various levels is not always in the same direction. The ore body, in fact, has undergone an apparent torsion, which is shown by the table showing the trend of the major axis at the successive levels :

No.	Length, Feet.	Width, Feet.	Trend of Major Axis.
3	..	...	N. 50 W.
4	660	270	N. 43 W.
5	510	210	N. 45 W.
6	510	270	N. 64 W.
8	280	...	N. 88 W.

Mining and Metallurgical Patents.

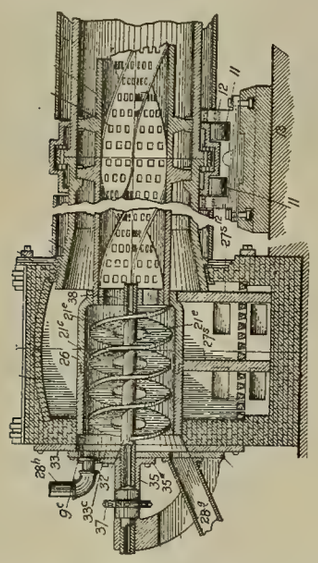
PATENTS ISSUED JULY 4, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF EXTRACTING COPPER FROM ITS ORES.—No. 793,186; G. Gin, Paris, France.

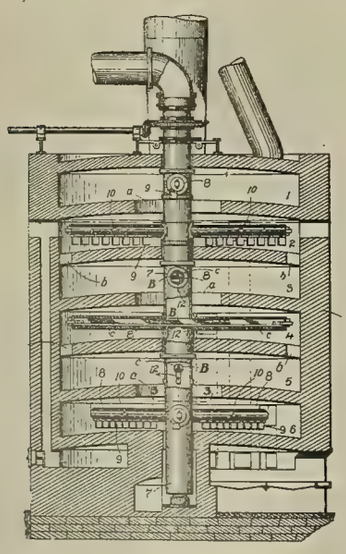
Herein described process of treating copper ore containing iron, consisting in roasting ore, lixiviating roasted ore with solution of sulphurous acid, heating resulting solution to temperature sufficiently high to precipitate iron sulphite and sulphate and decompose cuprosocupric sulphite contained in solution, then filtering solution, washing precipitate with water, permitting oxidation of residual sulphate to form sulphate of iron, and rewashing residue to remove such iron sulphate.

ORE TREATING FURNACE.—No. 793,816; A. M. Beam, Denver, Colo.



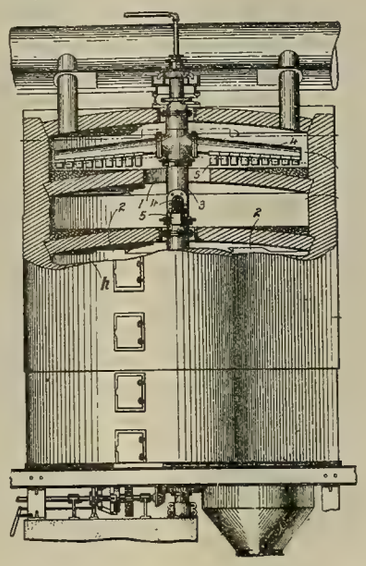
In ore treating furnace rotary flue cylinder, connected with stack at one end, other extremity extending into combustion chamber, circular, stationary conduit, extending through combustion chamber in concentric relation to flue cylinder, one end of conduit extending into discharge opening in side of combustion chamber, suitable means for supporting conduit, ore cylinder, concentrically located inside and attached to flue cylinder and projecting into stationary conduit, means for conveying ore through ore cylinder and into conduit, second flue cylinder concentrically located inside and attached to ore cylinder and extending through conduit, its ends projecting into second combustion chamber and into smoke chamber, and series of helicoidally arranged wings secured to portion of central cylinder extending through conduit.

ROASTING FURNACE.—No. 794,118; C. H. Repath, Anaconda, Mont.



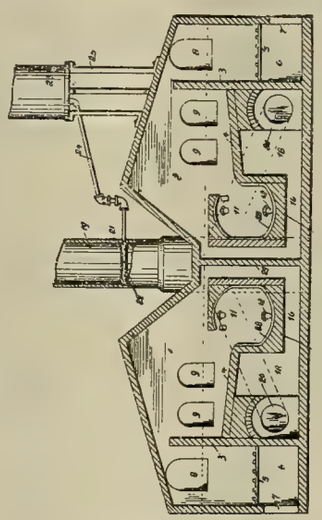
In furnace having one or more hearths, central hollow shaft passing through hearths, structural members radiating from and passing through walls of shaft into several hearths, and hollow rabble arms passed over structural members and supported thereby.

ROASTING FURNACE.—No. 793,939; F. Klepetko, New York, N. Y.



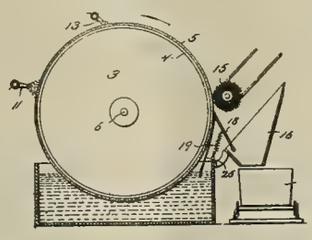
Rabble arm adapted to rotate about fixed axis, having series of rakes whose depth increases as they approach axis.

FURNACE.—No. 793,938; J. Kirby, Pittsburg, Pa.



Furnace comprising firebox, ore smelting hearth located adjacent to firebox, collecting basin constructed below hearth and having top, means for removing products from basin, means for conveying waste products of combustion from furnace over top down rear end and under bottom of basin and in direct contact with top, rear wall and bottom of basin.

APPARATUS FOR SEPARATING SLIMES, ETC., FROM METAL-BEARING SOLUTIONS. — No. 793,720; E. L. Godbe, Salt Lake City, Utah.

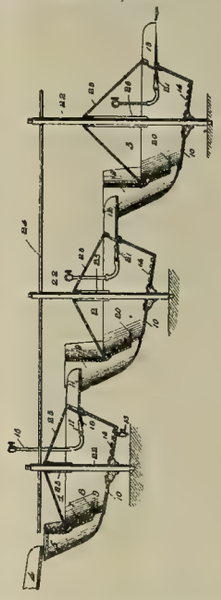


Apparatus of class described comprising tank, revoluble drum working therein, filtering medium fixed to periphery of drum, suction mechanism coacting with interior of drum, scraping device coacting with its exterior, and apron depending from scraper adjacent to face of filtering medium and entering tank to maintain vacuum within drum.

UTILIZATION OF FLUE DUST. — No. 794,153; C. S. Price, Westmont, Pa.

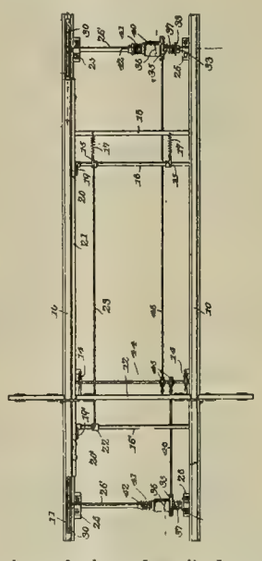
Process of utilizing finely divided ore or flue dust which consists in mixing approximately four parts of same with one part of clay, sufficient water to make stiff mass, forming same into plastic and coherent masses or plastic lumps, and charging lumps into blast furnace.

GOLD SEPARATOR AND CONCENTRATOR.—No. 793,945; R. T. Marshall, Merion Station, Pa.



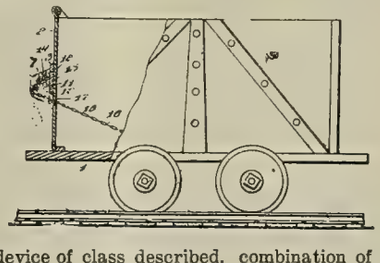
Machine of class described comprising plurality of pans, each of which is provided with inclined bottom, with semicircular hopper discharging onto bottom, and with spout projecting into hopper of next adjacent pan, lip projecting inward from hopper, and spout, and amalgam plates carried by hopper lip and first pan of series.

MINE DOOR OPERATING DEVICE —No. 793,813; S. T. Bailey, Mount Hope, W. Va.



Mechanism of class described, combination with door, of train-operated members arranged on opposite sides of door, means for transmitting movement from both members to door, and means for holding door in open position and rendering both transmitting means inoperative after door opening movement of either member until entire car or train has passed beyond operating means.

CAR DOOR LOCK.—No. 793,663; C. O. Johnson, Lanse, Pa.



In device of class described, combination of movable car body, door therefor, lock means for door comprising catch pivoted thereto, extension projected from catch, pivoted hook engaging extension, tail extending from hook, pivoted gravity bar provided with loop receiving tail aforesaid, weight at one end of bar, and connection secured at one end to car body and passed through door and connected with catch.

Concentration of Silver-Lead Ores.*

Written by V. F. S. Low.

The following paper is intended to apply to the concentration of the silver-lead ores at Broken Hill, New South Wales, generally, but more particularly to the process as applied to the ores in the Block 10 mine.

It is the writer's object to give a few figures which he found difficult to obtain when first engaging in practical work. At that time no text-books were at hand from which it was possible to get sufficient details for practical working purposes.

It is first supposed that the mine has been thoroughly explored and has been found to contain a lode sufficient in size and quality to warrant the erection of a concentrating plant. The points then to determine are:

1. The quantity and cost of water available for steam making and ore dressing purposes.
2. The most convenient site for the mill.

The capacity of the mill, supposing that the necessary capital is available, will be governed mainly by—

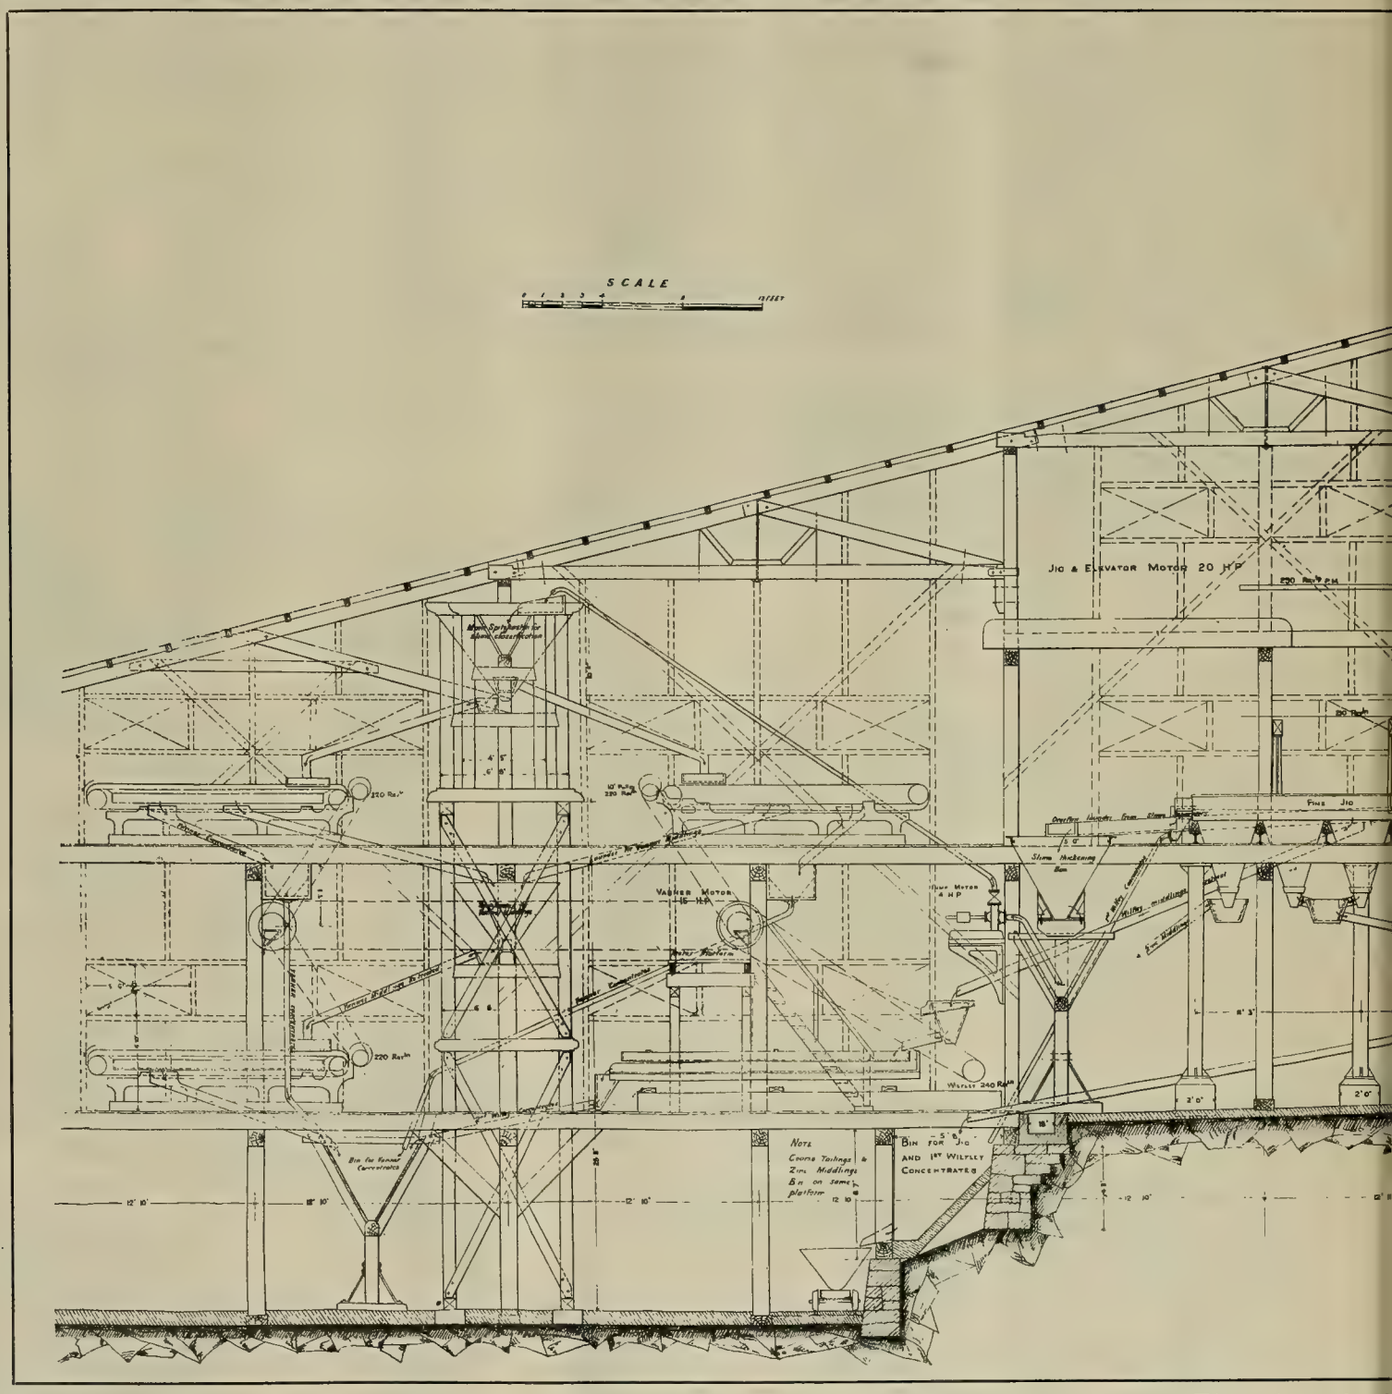
(a) The amount of water obtainable at a reasonable cost.
(b) The size of the ore body.
(c) The rate at which the ore may be mined.

In the generality of cases the water pumped from the underground workings may be used for ore dressing purposes, but it may be necessary to augment the quantity from other sources. Generally speaking, the daily consumption of water for steam and ore dressing purposes may be taken at 100 to 120 gallons per ton ore treated. Much of the water is used over again several times, but there is considerable loss owing to the amount of water that goes away in the tailings, slimes, concentrates, etc.

Having satisfactorily arranged the magnitude of operations to be carried on, the next move is to select the millsite. The first point to be borne in mind is that the mill must not be situated on top of the lode, or in such a position that it will be affected by the extraction of the ore from below. This is a point of vital interest, as more than one case may now be instanced on the Broken Hill field where the placing of plant on the surface above or near the lode has led to most disastrous consequences. Even though there should be a site on the outcrop ideal in all other respects, it should be rejected solely on account of its insecurity.

Having fully determined that the mill must be situated away from the lode and be out of all danger of depressions of the surface; surface cracks, or creeps, the most suitable hill should be selected. In some cases this may be situated some distance from the hauling shaft, but it is not advisable to go to a very great distance. A hill is chosen for the location of the contemplated mill in order that there shall be no further lifting of material after the crude ore has once been placed in the mill bins. If a good site be obtainable, matters can be so arranged that the work of transporting all material from one stage in the dressing to the next, until it finally leaves the mill in the form of concentrates, slimes, or tailings, can be done by gravitation. The only materials then to be elevated are the re-treatment returns. The return water, of course, must be pumped up again.

Having chosen the millsite, it will next be necessary to determine the position of the storage bins for crude ore. On the Broken Hill field the crude ore is generally broken underground to such a size—about 10x8 inches—as can be fed into a No. 5 Gates breaker. The breaker is sometimes placed at or near the brace, and here the first reduction takes place, but the breakers are often contained in the mill building itself. Where the mill is situated at any distance from the shaft, the first reduction should take place at the brace, and care should be taken to have matters so arranged that the breaker is placed below the first storage bin instead of above it, as is occasionally the case.



SCALE
Jig & Elevator Motor 20 H.P.
Varner Motor 15 H.P.
Note
Coarse Tailings & Zinc Middlings Bin on same platform
Bin for Jig and 1st Wilfley Concentrates

Side Elevation of 36

By tipping directly from the landing brace into the first bin, the Gates breaker is to a great extent independent of any temporary stoppages in the hauling arrangements, and the hauling need not necessarily stop on account of any slight derangement of the Gates breaker. At the foot of these bins, which should hold at least eight hours' ore supply, there should be at least one spare breaker beyond actual requirements, for, if the mill is to be run continuously day and night, repairs must be made from time to time to the reducing machinery during working hours. By having one spare breaker this could be done without hindrance to the mill supplies.

After the ore has been reduced, by passing through the Gates breakers, to a size sufficiently small to go to the rolls, it should pass into small bins of a few tons capacity from which to be taken and placed in the mill storage bins at the top of the mill building. The mill bins should be capable of storing sixteen hours of ore supplies at the least.

*Abstract Trans. Aus. Inst. Min. Engrs.

Many different classes of rotary breakers are now in the market, some of which are of good and others of inferior design. It is unnecessary to go into any details of these machines, as full information can be obtained from trade catalogues. The main features to be observed when ordering a breaker are:

(1.) That the bearings are well protected from dust.

(2.) That where hard material, such as rhodonite, has to be crushed, it is best to use a solid brass eccentric. The eccentric usually supplied is made of steel or cast iron with babbitted wearing faces and is unsuitable for crushing the hardest materials.

With regard to the crushing of ore, the mill engineer should lay down for himself the following rule: "Never feed into a crushing machine material which is already small enough to pass through it without further reduction." If this matter is not attended to extra work is given to the rolls and crushers, thereby causing unnecessary wear, tear, delays and excessive sliming. In order to separate the coarse from the fines, the ore is first of all tipped over a "grizzly" or grid of inclined steel bars placed over the first bin. The ore delivered from the brace having been tipped on to the grizzly, the material already fine enough to go to the rolls passes between the bars, and the large material passes to the bins in readiness for the breakers. The fine material which has passed through the grizzly goes either into a separate bin ready for removal to the mill, or else runs into the same bin as the crushed product issuing from the breakers.

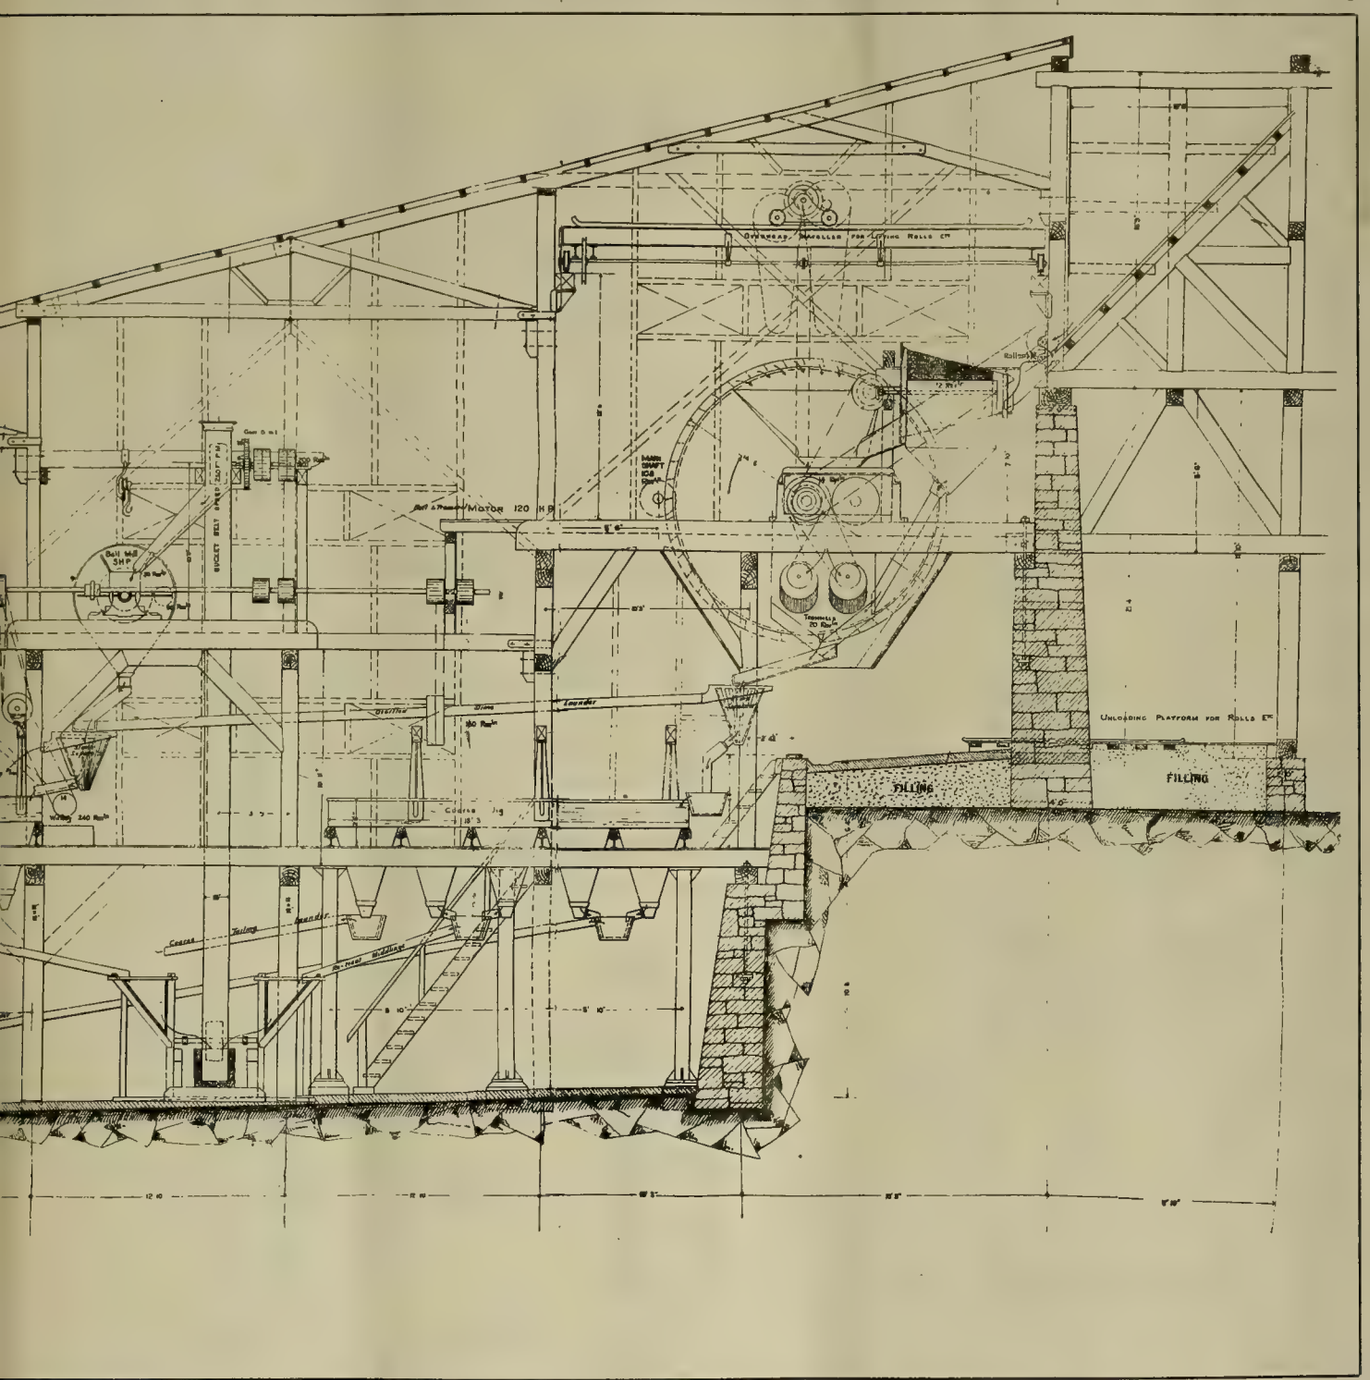
The ore, having been placed in the mill bins, is now ready for further reduction and subsequent concentration. An up-to-date mill will be so arranged in sections that each section is totally independent of the others. By this means it is possible for the whole process of concentration to go on in one part of the mill while the rest of the mill is idle. In the older form of mill, in which this used not to be the case, much loss was sustained, as an interruption to one part of the mill often meant the stopping of all machinery for a considerable period.

Where the mill is arranged in sections, each section will probably consist of rolls, trommels, coarse jigs, fine jigs, ball mill, slime tables, vanners, spitzkasten, and the necessary elevators, pumps, etc. On leaving the bins the ore for each section passes through a conical trommel about 6 feet long and 3 feet in diameter at the large end and 2 feet in diameter at the small, having a cover made of 14-gauge iron punched with round holes ½-inch diameter. The trommel, supported on external rollers, makes twelve revolutions per minute, and about ½ H. P. is required to drive it. The oversize from the trommel is fed to the rolls, the trommelled material going towards the jigs.

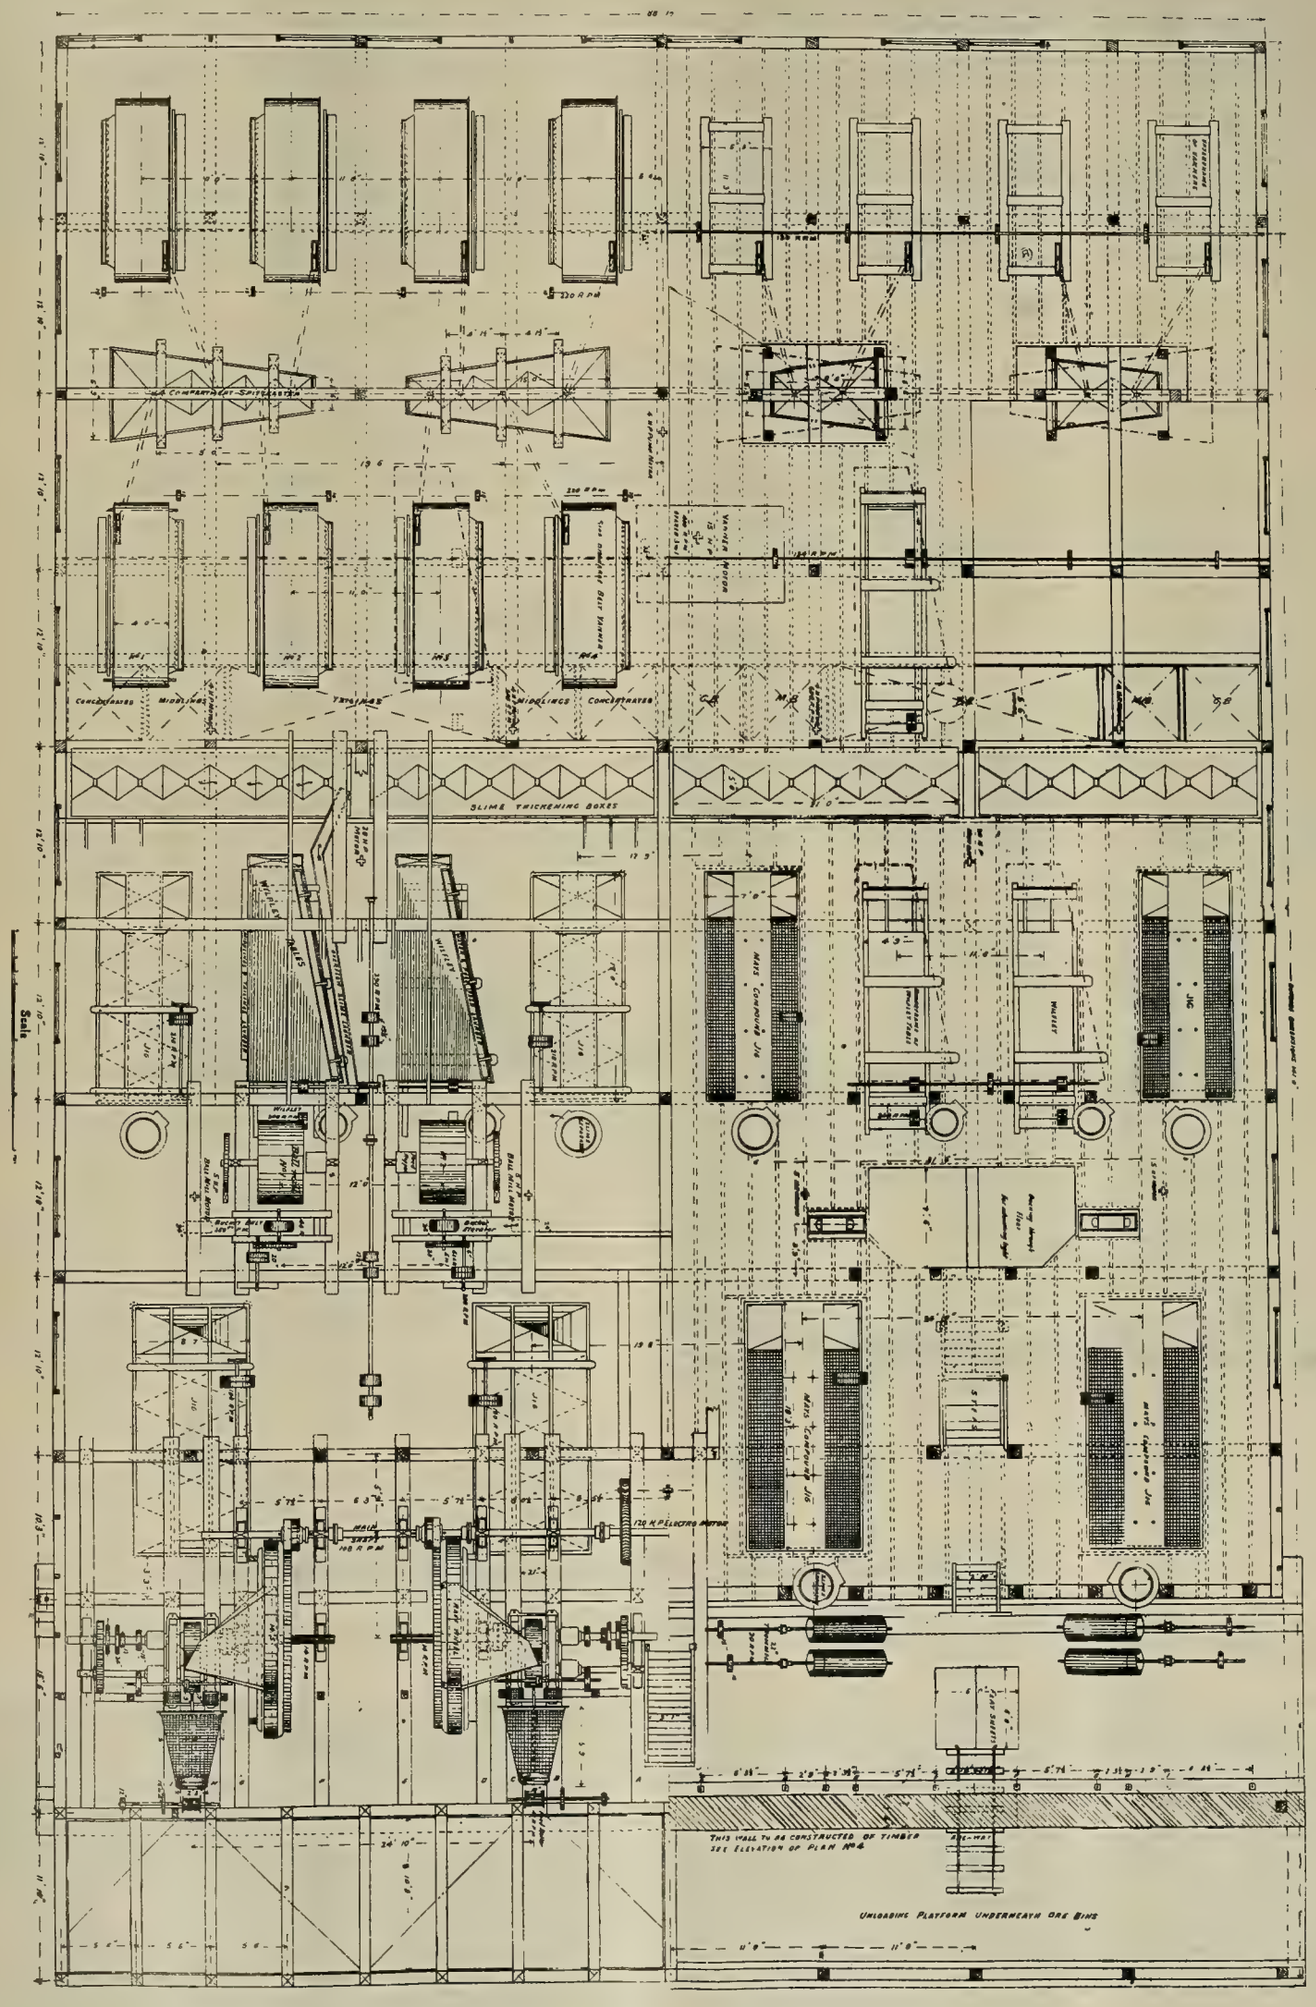
Many kinds of rolls are in use at the different mills, but those constructed for the present plant are of the Cornish type, driven by gear wheels, the gear being 7 to 1. The shells for these rolls are 2 feet 6 inches in external diameter and have coned centers, bolted together in such a way that the shells when worn may be expeditiously removed. Each pair consists of a plain roll and a flanged roll into which the plain one fits. Either manganese or toughened steel is used for making these shells, which work at the rate of fifteen revolutions per minute, are capable of crushing 1000 tons per week from 1½-inch to ¾-inch mesh for average material, and require a driving force of 25 H. P. Such material as has passed through each set of rolls goes to two parallel trommels, 6 feet in length and 22 inches in diameter. These trommels make twenty revolutions per minute, are set in an inclination of 1 inch to 1 foot and have screens composed of 14-gauge iron punched with round holes 2½ millimeters in diameter. Such material as is too large to pass through the mesh of the screen is returned again to the same set of rolls, while the trommeled material, meeting with the trommelings from the conical machine, passes to the hydraulic classifier at the head of the coarse jig.

The hydraulic classifier is a cone-shaped hollow casting of iron ⅜-inch thick, is 2 feet in diameter at the base and 2 feet 6 inches deep. The apex of the cone is placed downwards, and is perforated by two holes, ⅜-inch diameter, for water inlet, and by one discharge hole, the stream entering by the inlets being so regulated that there is always a slight overflow at the upper edge of the cone. The feed then coming in at the top of the classifier meets the rising flow of water from the inlets; the slimes are then carried away with the overflow water, the heavier particles falling into the bottom and finding their way through the discharge opening on to the head of the coarse jig.

The jigs are divided into two classes—coarse and fine. Each coarse jig consists of eight working and two tailings compartments or divisions—five on each side—and each working compartment consists of a hopper with a hutch and separate plunger at the top. Each hutch is 3 feet 6 inches by 2 feet 6 inches and has a bottom composed of 6-mesh woven brass wire screening, which rests on cross bars of iron, and is kept in position by iron grids placed on



Concentrating Mill.



Plan of Concentrating Mill.

top and bolted through to the crossbars. Each plunger is 3 feet 6 inches long and 14 inches wide, and has a clack opening in it 2 feet 6 inches by 6 inches.

The plunger and hutch being in the same hopper, which is kept filled with water, and being separated at the top only by a wooden partition, any motion given to the water by the plunger is communicated to the material resting on the sieve. The object in having a clack and clackway in the plunger, instead of having the plunger solid, is that there shall be as little downward suction in the hutches as possible, and that the water shall have, as far as possible, a quick upward motion and a slow return. In this way ore particles are allowed to settle, more or less, according to their specific gravities, the denser particles passing through the ragging and sieve into the hopper below, the less dense being carried forward on to the next hutch. In this way the gangue eventually finds its way over the end of the fourth hutch and is removed to the tailings dump. The plunger clack is a pine board loosely bolted to the bottom of the plunger, from which it has a clearance of ⅛ inch on the upward stroke. The use of a clack on the plunger does away with much of the classification which would otherwise be necessary before jigging. Each plunger of the coarse jigs makes 180 pulsations per minute, and each jig, requiring 2 H. P. driving force, is capable of treating 6 or 7 tons of ore per hour. The discharge of products from the hoppers goes on continuously, material Nos. 1 and 2 being carried away to bins for final shipping to the smelters, that from Nos. 3 and 4 to undergo further crushing and re-treatment in the fine jigs. No. 5 is taken to the tailings dump.

The re-crushing of material from the last two hutches of the coarse jigs to 20 to 25 mesh is done in Krupp ball mills which make 30 revolutions per minute and require 8 to 10 H. P. for motive force. The material leaving the ball mill passes through a system of classification at the head of the fine jigs similar to that which took place at the head of the coarse jigs.

The fine jigs are the same in principle as the coarse, but are run at a speed of 200 vibrations or strokes per minute. The hutches and plungers are smaller—3 feet 4 inches by 24 inches and 3 feet 4 inches by 12 inches respectively—but their number is the same, viz., 5 of each on each side of the jig. About 1½ H. P. is required to drive each jig having a capacity of about 4.5 tons per hour. Each fine jig has to deal with about 60% of the crude material which had, in the first place, been sent to the coarse jigs. The material discharged from the first two hoppers of the fine jigs, i. e., from hutches 1 and 2 on each side, is sent to the shipping product bins, while that from hoppers 3 and 4 is returned to the jig after having again passed through the ball mills. The material from the fifth compartment is sent to the zinc middlings dump.

The fines and slimes from the classifiers at the heads of the coarse and fine jigs are settled in spitzkasten, the coarser material being treated on Wilfley tables, the finer flowing away, and, after further classification, being treated on belt vanners.

In the mill under consideration no middle product is returned to any table over which it has already passed, and, therefore, the return launder and elevator on the Wilfley table have been dispensed with. The Wilfley table is run at a speed of 220 to 240 vibrations per minute and has a capacity of about 1 ton per hour for material up to 30-mesh. If, however, the material is from 30 mesh down to slimes, the capacity is lessened to about ½ ton per hour. About ¾ H. P. is required for driving a fully loaded Wilfley. Krupp tables, very similar in action to the Wilfleys, are also to be used, but all the finer slime work is to be done on belt vanners.

The spitzkasten used for classifying the slimes are generally made of timber planks about 2 inches thick, and have dimensions after the following proportions:

Length, top 15 feet, bottom 10 feet.

Depth, 2 feet 1 inch at head, sloping to 4 feet 8 inches.

Breadth, 2 feet 8 inches at top, widening to 7 feet 1 inch at the end.

Two different kinds of elevators are used for elevating returned material, viz., raff wheels and elevators. The raff wheels are 14 feet in diameter and make fifteen revolutions per minute. A good form of elevator is one having buckets 7x5x5 inches bolted to a belt 8 inches wide at a distance 15 inches from each other. The driving is done from above by cog wheels geared at 3 to 1, the bucket belt passing around drums 2 feet in diameter, top and bottom, and having a speed of 250 feet per minute. A good slope for elevators is about 80°.

As regards the quantity of water in circulation, it is estimated that for every ton undergoing treatment 1500 gallons of water are in use in the mill at the same time. The loss of water, as has already been stated, is estimated at 100 to 120 gallons per ton of ore treated. The mill circulating tanks, which are placed at sufficient height for all mill purposes, are generally made cylindrical in form, and composed of iron, the thickness of which, of course, is in proportion to the depth of the tank. Other separate sets of tanks are used for settling the slime from the water before the latter is pumped back to the mill circulating tanks. The slime settlers are generally rectangular in plan and have a sloping bottom. They may be made of iron, timber or masonry. The tanks are fitted on the lower side with suitable discharging doors and launders for periodically carrying away the slimes.

For a mill capable of treating 4000 tons per week, and laid out in four independent sections, the following horse power would be required:

2 Gates breakers	40	H. P. each—total	80 H. P.
4 feed rolls.			
4 Cornish rolls			
4 trommels	30	H. P.	120 H. P.
8 parallel trommels			
4 coarse jigs	2	H. P. each—total	8 H. P.
4 fine jigs	1½	H. P. each—total	6 H. P.
4 Wilfley tables	¾	H. P. each—total	3 H. P.
4 ball mills	10	H. P. each—total	40 H. P.
2 Krupp tables and 24 vanners			15 H. P.
4 elevators	5	H. P. each—total	20 H. P.
5 slime pumps	2	H. P. each—total	10 H. P.
1 water circulating pump			25 H. P.
1 water circulating pump			10 H. P.
1 water circulating pump			1 H. P.

The above list corresponds closely in most respects with that of the machinery to be installed in the new Block 10 ore dressing mill, the motive power of which will be electricity throughout, thus making a new departure as far as the Broken Hill field is concerned.

A mill arranged as above will probably give from each ton of crude ore 20% of concentrates, 20% of jig tailings, 7% of fine slimes, 7% of vanner tailings and 45% of zinc middlings.

A most important and yet very difficult matter in connection with milling operations is the sampling of the crude ore and mill products and by-products. The practice of "working back" for assay values is one which should be discountenanced in all milling operations. By "working back" is meant the calculation of the assay value of the crude ore from the values of the mill products which have been obtained by sampling and subsequent assay. For instance, the weight of the crude ore is known, as are also the weight and assay of the concentrates, middlings and tailings. The assay value of the slimes is known and the weight calculated. From these figures an assay value is calculated for the crude ore, and from this assumed assay value the recovery of metal contents is calculated, much, as a rule, to the apparent advantage of the concentrator. The only true and correct way to calculate the recovery is to take a proper sample of the crude ore after the first crushing, and before the ore has in any way come in contact with the mill water; then, having its correct weight and the correct weight and assay of all other material, a very close approximation of the true state of affairs can be arrived at. It is true that the recovery as calculated from week to week varies from the theoretical amount, being sometimes above and sometimes below, but this can only be expected, where large and varying quantities of material are continuously in transit. When averaged over a considerable period—say three months—the quantities come out very closely if due care has been observed in the sampling.

(TO BE CONTINUED.)

Personal.

R. W. PURDUM, manager Sunnyside mine, is at Roosevelt, Idaho.

A. C. CARSON has charge North Butte Copper Co. at Butte, Mont.

T. R. HENAHEN is superintendent Silverton M. Co., Silverton, Colo.

R. C. GEMMELL is sampling the Utah copper mine at Bingham, Utah.

ANDREW NOCE has resigned as foreman Oneida mine, near Jackson, Cal.

R. C. CORBUS has taken charge Oregon mine, near Orogrande, Idaho.

J. H. SCONT has been appointed manager Bassick mine at Querida, Colo.

C. L. TEWKSBURY is superintendent Wyoming M. Co., near Kirwin, Wyo.

ADOLPH RIEGELS is superintendent American Nettie mine, near Ouray, Colo.

JOHN H. MACKENZIE AND M. L. REQUA are at their mines at Ely, Nev.

C. C. BARKE is manager Rattler mine, near Centerville, Shasta county, Cal.

FRED. G. FARISH has gone to Parral, Chihuahua, Mexico, on professional business.

C. V. TURNER of Nevada City, Cal., is examining mines at Bishop, Inyo county, Cal.

G. MCM. ROSS is in San Francisco from the Union copper mines at Copperopolis, Cal.

RICH. TREVARTHEN has been appointed manager Old Gold mine, Cripple Creek, Colo.

H. C. BELLINGER, manager Yampa smelter at Bingham, Utah, has been visiting Butte, Mont.

H. V. WALLACE has been appointed manager Sombreretillo M. Co., near Saric, Sonora, Mex.

W. S. KEITH has returned to the Takilma smelter at Waldo, Oregon, as assistant superintendent.

M. L. HEWITT, manager Cataract Copper M. Co., has returned to Basin, Mont., from a trip abroad.

M. B. KERR, E. M. of San Francisco, Cal., has gone to Inyo county, Cal., to make mine examinations.

SAML. JAMES is superintendent Arcos smelter recently started at Sultepec, State of Mexico, Mex.

ARTHUR DAY of Butte, Mont., has been appointed superintendent Yampa smelter at Bingham, Utah.

C. P. OLIVER has been appointed superintendent Colorado Tungsten Corporation at Nederland, Colo.

A. H. ELFTMAN of Minneapolis, Minn., has been visiting Thunder Mt., Idaho, and is now at Goldfield, Nev.

T. R. BROOKS succeeds F. M. Leland as manager mining department Risdon Iron Works, San Francisco Cal.

D. J. BADGER has been appointed superintendent Colorado Tungsten Corporation's mill at Boulder, Colo.

A. H. CARPENTER of Denver, Colo., has been appointed manager Takilma smelter at Waldo, Oregon.

J. E. BAMBERGER, president Daly-West M. Co., has returned to Salt Lake City, Utah, from an Eastern trip.

NATHAN BURLINGHAM of Glendale, Cal., has been examining mines at Mineral Park, near Chloride, Ariz.

B. W. PAXTON of Santa Rosa, Cal., is examining the Texada island iron properties in the Nanaimo district, B. C.

F. M. SMITH has been appointed manager East Helena smelter, American S. & D. Co., at East Helena, Mont.

A. J. MULLER is again manager Ayeinm mine, Ashanti Goldfields Co., in the Gold Coast colony, West Africa.

LOUIS DAHL of Lewiston, Idaho, has left to take charge Bangor-Alaska placer mine, Alaska, for the summer.

WM. BALL, superintendent Lower Mammoth mine at Eureka, Utah, has returned to the mine from a trip through Idaho.

J. R. YEARDSLEY has been appointed superintendent milling department Pfau Gold M. & R. Co.'s plant at Cherry, Ariz.

V. G. HILLS has been appointed consulting engineer Colorado Tungsten Corp., operating wolframite mines at Nederland, Colo.

H. P. LITTLE of Sandon, B. C., has charge construction of a concentrator for the East Pacific M. & M. Co. at Helena, Mont.

J. L. SNYDER, who is developing a copper property at Oro Grande, in the Altar district, Sonora, Mex., is visiting in Los Angeles, Cal.

W. J. DEEGAN, formerly of Red Lodge, Mont., is superintendent Galena Ridge M. Co. and Shoshone Mountain M. Co. at Kirwin, Wyo.

ROBT. M. RAYMOND, manager El Oro M. & R. Co., has returned to El Oro, State of Mexico, Mex., from a trip to Boston and New York.

J. H. MCCLARREN of Pittsburg, Pa., controlling the Pittsburg Lead M. Co., is at Wallace, Idaho, superintending mining operations on Nine Mile.

W. C. MILLER has been appointed general manager of all the mines operated by the Federal M. Co. at Wardner, Mace and Burke, Idaho, succeeding E. J. Roberts.

H. C. WHIPPLE has completed the cyanide plant for the El Oro M. & M. Co., and is now constructing the 120-stamp mill and cyanide plant for the Black Mount M. Co., Magdalena, Mexico.

H. S. NULLIKEN has resigned as superintendent Monterey plant of the American S. & R. Co. to become metallurgical engineer for the Cia Minera de Penoles, at Mapimi, Durango, Mex.

E. B. BRADEN, manager East Helena smelter of the American S. & R. Co., has been appointed a member of the executive board of the American Smelters Security Co. and will be in charge of the Tacoma and the Everett smelters, and the Selby smelter at San Francisco.

Books Received.

"Official Proceedings of the Twelfth National Irrigation Congress" held at El Paso, Tex., November, 1904, compiled by G. E. Mitchell.

Part IV of "Report of Progress of Stream Measurements for 1904," by M. R. Hall and J. C. Hoyt, gives data on the Santee, Savannah, Ogeechee and Altamaha rivers and eastern Gulf of Mexico drainages.

As extracts from "Mineral Resources of the United States for 1904" the United States Geological Survey has issued "The Production of Graphite in 1904" and "The Production of Monazite, Zircon, Gadolinite, and Columbite or Tantalum Minerals in 1904."

Trade Treatises.

Bulletin No. 53 from the Crocker-Wheeler Co., Ampere, N. J., describes direct current lighting and power generators.

The Wild crushing mill is elaborately illustrated and described in a fine pamphlet issued by the S. H. Supply Co., Denver, Colo.

Catalogue 124 from the Allis-Chalmers Co., Milwaukee, Wis., describes the Overstrom concentrator. A colored plate on page 21 graphically portrays the operation of the table.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

Tin has been found at a number of places in Alaska, but as yet there has been little production. It has been found in place in Seward peninsula, at Lost river and Cape mountain, and is reported from Brooks mountain, Ears mountain and the Darby mountains. Alluvial deposits have been found on Buck creek and Old Glory creek, and are reported on the Arctic slope north of Buck creek, on Gold Bottom creek, near Nome, and at one or two other places. Pebbles of stream tin have been found in the gold placers of Cleary creek, near Fairbanks, and miners report it in the gold placers of the Koyukuk. At Lost river the country rock is a Silurian limestone, through which is thrust a granite boss about ½ mile in diameter. Quartz-porphyry dikes also cut the limestones in various places. These dikes are frequently much kaolinized, and in other places replaced by fluorite, which sometimes colors the dike violet or purple. The cassiterite occurs disseminated through the dikes, particularly in the kaolinized portions, and in veins in the limestone. Small amounts of tin are also found with pyrite in the granite. The accompanying minerals are tourmaline, topaz, fluorite, zinnwaldite, wolframite, quartz, epidote, garnet, chalcopyrite, iron pyrites and galena. About ten tons of ore, estimated to carry 10% to 20% of tin, have been produced. At Cape mountain cassiterite has been found near the contact of the Carboniferous limestone and slates with granite, occurring in both sedimentaries and granite. The Buck creek placers occur in a slate country rock, which is probably underlain at no great depth by granite. The gravel is nearly all of slate and quartz. Pyrites, hematite and a small amount of gold are the accompanying minerals. The cassiterite apparently comes from small stringers in the slate. During the last two years probably 100 tons of stream tin, carrying 60% tin, have been produced.

ARIZONA.

Cochise County.

(Special Correspondence).—An important strike has been made in the Warren district, in the Shattuck & Arizona property, in a drift at the 700-foot level.——The Calumet & Arizona at Bisbee has completed putting in hose carts and hose at the several shafts of the Bonanza Circle which will afford fire protection.

Bisbee, July 11.

Gila County.

L. F. Rotsler reports of his mine at Dripping Springs, 40 miles from Globe, that rich gold ore has been struck in a drift from the bottom of the 100-foot shaft. The owners have decided not to ship any ore, but to resume sinking.——J. M. Frederick and H. S. Buckner have bonded the Proctor mine on the divide between Mineral and Pinto creeks, near Globe. The claim is developed by a tunnel 300 feet long.

Maricopa County.

It is reported that a hoist capable of sinking to 1500 feet is to be put in at the new shaft of the Vulture mine, near Wickenburg. G. E. Sanders and W. B. Troy have charge.

Mohave County.

It is reported that a 60-ton smelter is to be put up at the Desert Queen mine, near Quartzsite. J. J. Wyatt of Los Angeles, Cal., is manager and superintendent.

Pinal County.

The Troy-Manhattan C. Co. at Troy have sunk the Buckeye shaft 375 feet. The company is preparing to make a smelter run next month, coke being now received.

Yavapai County.

The Crown King M. Co. at Crown King is concentrating seventy tons of tailings daily at Crown King.

At Val Verde, the site of the new smelter has been surveyed and ground is being broken for the foundation of the smelter. It is expected to have the sampling works completed by August 15th. The new sampling works will be operated in connection with the smelter. There will be two smelters, one for copper and one for lead ores, with a combined capacity of 800 tons a day.

M. Bradley, superintendent for the Buffalo M. Co. on Cherry creek, has purchased a gasoline engine, a blower and 1000 feet of air pipe. The tunnel is in 1000 feet and will be driven 500 feet more. The values are copper, gold and silver.—— S. H. Anderson reports that the Great Republic shaft, near Cordes, is 578 feet deep.—— In the double-handed drilling contest at Prescott, G. Dahlin and A. Nyberg drilled 30.7 inches in fifteen minutes. Dahlin drilled 15½ inches in the single-handed contest.

CALIFORNIA.

The Los Angeles Chamber of Commerce has taken action toward amelioration of the conditions on the deserts of southern California and Nevada which are again causing the deaths of many prospectors and travelers from thirst. The Chamber has twice before memorialized the various county governments in which these deserts are located, in an effort to save the lives of travelers, but so far there has been no action taken. As the heated season approaches, deaths on the desert are again becoming frequent, and within the last two weeks it is stated that twelve people have perished from thirst. The secretary was directed to prepare a letter to the supervisors of Los Angeles, San Diego, San Bernardino, Riverside, Inyo and Kern counties, in California, and Lincoln, Nye and Esmeralda counties, in Nevada, calling attention to the conditions on the desert and the previous efforts of the Chamber to have remedies provided. It was also decided to prepare an accurate and complete map of the desert country for free circulation.

El Dorado County.

The Last Chance mine at Coloma is in operation with seventeen men under the supervision of John Gray of Jerome, Ariz.——It is reported that work has been commenced at the Rosencranz mine, near Garden Valley, under the supervision of W. F. Holland. A new shaft is to be sunk on the mine and levels run 100 feet apart.

Mariposa County.

J. C. Rhoads of the Grimshaw mine, near Mariposa, states that sinking and drifting are being done with nineteen men. The ore is being milled at the Organita mill.

Nevada County.

Operations have commenced on a claim on Indian Flat, near Grass Valley, by the Prospecting Co. in which A. D. Foote, C. E. Clinch, R. Walker, T. Marshall, A. L. Gill, A. Hall and L. P. Larue, all of Grass Valley, are interested. The 50-foot shaft is being cleaned out and will be retimbered to the bottom. A. Hall has charge.

Work has been started at the Banner mine, near Nevada City. The old works will be removed and the new plant put in. The pumps will commence to lower the water and it is expected that the 700-foot shaft will be cleared in a short time.

Placer County.

Superintendent D. M. Ray of the Placer Gravel G. M. Co. at Last Chance is putting in a gasoline engine to ventilate the mine.

Shasta County.

Work has been started at the Graham group, near De Lamar, by A. Rossi.——W. F. Arnold is working his claims at De Lamar.

Sierra County.

Work is to be started at the Rainbow mine, near Alleghany.——The Tightner shaft at Alleghany is down 80 feet. The rich ore is holding out.

Siskiyou County.

The Yreka Creek Dredger Co. has put in a centrifugal pump below the pit in which the boat was built, 1 mile north of Yreka, for the purpose of pumping back the water running out, in order to keep the boat floating until machinery of same is ready to sink down to bedrock. The pump is run by electricity. The machinery is being placed as rapidly as possible, and it is expected will be ready for starting August 1st.——The water supply in the different mining camps is getting short, owing to the snow disappearing on the highest mountain summits, together with drying up of springs on account of warm dry weather. The result will be a shut down in hydraulic and placer mining until cool weather comes again. Many of the mines have already shut down.

Sonoma County.

A 5-stamp mill and other machinery is to be put in to develop a mine in Dry Creek valley, near Santa Rosa, by A. Lencioni, who claims to have uncovered a ledge carrying nickel, gold and copper. N. Silva has charge of the work.

Stanislaus County.

The California & Nevada Ore Co. have contracted to build an ore testing plant at Oakdale.

Trinity County.

The half-interest owned by Mrs. Phillips of San Francisco, in the Brown Bear mine, at Deadwood, has been sold to McDonald Bros., the former owners. The price paid is said to be $100,000.

Tuolumne County.

The hoist, blacksmith shop and mill at the Starr King mine, 3 miles above Carters, were entirely destroyed by fire on July 3. The loss is estimated to be $12,000, with some insurance.——At the Confidence mine at Confidence sixty men are employed. The 20-stamp mill is pounding continually on ore. Sinking the shaft was resumed on July 1 at a depth of 810 feet.——At the Longfellow mine, near Big Oak Flat, a raise is being made on the 400-foot level west from the main drift. Drifting is being done on the 300 level to the west, and on the 450 and 600 levels east, all in good ore. The shaft has been enlarged and retimbered to the bottom of the main shaft—600 feet. The ten stamps are dropping. The well at the pumping station on the creek will be sunk 10 feet and a drift run to make a larger reservoir for water, and when completed will furnish plenty of water for use at the mine and mill.

Stamps are dropping at the Clio mine at Jacksonville on good ore. The shaft is approaching the 200-foot level.——B. Addis has charge of the Lucky Find, 9 miles above Confidence. There is a 5-stamp mill on the mine and a concentrator will be put in.

COLORADO.

Boulder County.

In the double-handed drill contest at Boulder, Collins and Dopp of Jamestown drilled 33¾ inches in fifteen minutes, winning $400. In the single-hand contest F. Yockey drilled 24 inches.

It is reported from Eldora that the Mogul Tunnel will again start up. A disagreement between the operators and the tunnel management, as to their respective share of operating expenses, has been the cause of the shutdown.

Chaffee County.

In the Turret mining district a graphite deposit is being developed by the Ethel G. M. Co. of Detroit, Mich. Samples show the deposit to be amorphous graphite of good quality. The company is said to be putting up a mill for concentrating and refining the deposit.

Clear Creek County.

The Manda claims, on Douglas mountain, near Georgetown, have been sold to Pennsylvania capitalists. The claims are being developed by a crosscut tunnel, in 150 feet. The new company proposes putting up a 25-ton mill, in addition to mining machinery.——Operations have been resumed on the Fort Dodge group, on Leavenworth mountain, near Georgetown.

Manager J. J. May of the Newhouse tunnel, at Idaho Springs, says that work will be resumed on the breast of the big bore during July. It is reported that the tunnel will be continued ahead several hundred feet, when a lateral will be driven west which will ultimately connect with workings of the Old Town mine. For some little time the management of the Old Town has been making efforts to secure a right of way for a lateral from the Newhouse tunnel to the Old Town shaft. The distance to be driven is nearly 4000 feet, and the lateral will unwater a number of the best properties in Russell gulch, as well as permit of their operation at depth. The Old Town shaft is over 1500 feet in depth on the pitch of the vein, and the lateral from the Newhouse will cut underneath the shaft several hundred feet. It will require about two years' time to complete the connection, but in the meanwhile a considerable number of properties in Russell gulch will be enabled to resume operations which are now lying idle on account of the water in the mine workings. The Newhouse tunnel was located Feb. 13, 1891, and actual work was commenced in the fall of 1893. On Jan. 1, 1894, the machine drills were started. On Jan. 1, 1905, the breast of the tunnel was 14,570 feet from the portal, and the estimated cost of the work up to that time is placed in excess of $390,000, including equipment. The tunnel is 10x10 feet wide, with a double track, 18-inch gauge, with a space of 30 inches between the tracks for a distance of about 1400 feet. In the space between the tracks is a drain box, 14 inches deep by 2 feet in width, that carries the water from the tunnel. For the first 80 feet from the portal and at points where veins are cut, timbers have been used, but along the balance of the tunnel no timbering is required, as the cut has been made through solid rock. The grade is uniform—a raise of 5 inches in each 100 feet. From the 1400-foot point the double track size was reduced to 5x7 feet, or single-track tunnel, as this was thought the most desirable and practical, and this will be maintained to the proposed terminal in Quartz hill. The average progress made in the driving has been 200 feet per month. The power plant consists of three 80 H. P. boilers, two of which are used at a time, the one as a reserve; two 16x16 two-stage Norwalk compressors; one 22x24 two-stage Norwalk compressor; one No. 7 Root blower, driven by a 50 H. P. Atlas engine; one 30 H. P. high-speed engine connected with a 20 K. W. Westinghouse 500-volt generator; a 16 H. P. Baldwin-Westinghouse locomotive furnishes the motive power for the transportation of ore cars from the different properties operated from the tunnel, handling as many as twenty-five loads at a trip. The driving of the tunnel has been under the supervision of L. Hanchett as manager, with S. A. Knowles in personal charge up to a few months ago, when he left the employ of the company to superintend the driving of the Government's irrigating tunnel at Montrose, and J. J. May was placed in charge in his stead.

The St. Paul M. Co. has resumed development on its properties near Georgetown. It is expected that a power plant will be built at the base of Green Lake mountain and power drills used in driving the crosscut tunnel. W. L. Smith of Osage City, Kans., has been at the mine starting work. T. Guanella is superintendent.——Operations have been resumed on the Kingbird claims on Kelso mountain, near Georgetown, with L. Anderson in charge. The tunnel is in nearly 300 feet.

The Colorado Central mine has been bonded to F. A. Mazwell of Georgetown.——The Pelican mill of the Dives Pelican & Seven-Thirty M. Co., near Georgetown, has started regular work. According to the Georgetown Courier, the ore from the mine is fed into the crusher chute, which holds ten tons, and from this it is delivered to two 10x20 Blake crushers. The ore is crushed to 1½ inches, falling from crushers into a Jeffries pan conveyor which elevates the ore to top of mill, a distance of 122 feet on its pitch and 90 feet vertical. From pan conveyor ore is delivered to a horizontal belt conveyor, which distributes into the reserve ore bin at top and back of building. This bin is 52 feet long, 22 feet wide and 18 feet deep, holding 1000 to 1500 tons, depending upon the character of the ore. The ore is then fed from the bottom of this reserve bin through chutes, thence on to a second horizontal belt conveyor, delivering it through a Gates feeder, then on to the 16x36 coarse rolls, which are set to crush to ⅝ inch. At this stage water is added and washes the ore to the bucket mill elevator, where it is lifted to the first sizing screen of six mesh, the return from which going to the second set, or finishing rolls of same size as the coarse rolls. Thence it passes back to the same bucket elevator and back to screen. There are four revolving screens, which deliver three sizes, 6 to 8 mesh, 8 to 10 mesh and 10 to 18 mesh. Ore passing through 18 mesh is water-sized, thus giving four sizes, which are treated by eight side-discharge four-compartment jigs; the tailings from which are delivered to three 5-foot Huntington mills with 20-mesh screens. The pulp from Huntington mills flows into two sand pumps, which elevate it to a main distributing tank, from which it flows into two sets of sizing boxes, four to the set, making four water sizes, which are treated by seven Wilfley and three Cammet tables. The mill is driven by seven motors—one a 50 H. P. for crusher, a 50 H. P. for rolls, a 20 H. P. for jigs, a 20 H. P. for Huntington mills, a 7 H. P. for tables, a 15 H. P. for pan conveyor, a 5 H. P. for main belt conveyor, and a 2 H. P. for roll belt conveyor. J. H. Eaton is general manager. F. Graham is mill man.

Denver County.

A. B. Frenzel has arranged for building a large mill in Denver to concentrate uranium, vanadium, platinum, tungsten, molybdenite and other valuable minerals. Attention will be given to the separation of fine gold, platinum, osmium and iridium from black sand.

Dolores County.

The continued high price of zinc is encouraging the United Rico M. Co. to develop all its zinc-bearing properties, and in addition to the Atlantic Cable the company will soon commence operations on its Black Hawk, Yellow Jacket and Futurity groups.——The Rico Dolores M. Co. is arranging to operate its mines at Burns on a more extensive scale.——The Emma G. M. & M. Co. is shipping concentrates from its mill to Coke Ovens, and shipments to the Durango branch of the American S. & R. Co. will be resumed as soon as the road is reconstructed to Dolores.

Gilpin County.

It is reported that more machinery is to be put on the Modoc mine on Quartz hill, near Central City, operated under a lease and bond by the United M. & Ex. Co.—— R. Hastie, Jr., of Denver has taken a three years' lease

and bond on the Japan mine in Russell district and has done some sinking.——The Penn mill on North Clear creek, near Central City, has been started up on custom ores under the management of L. S. Newell, Jr., with J. Johnson as mill foreman. E. C. Holland is experimenting with the slimes in the creek from the Penn mill. ——Daily shipments amounting to sixty tons are being made from the Pewabic shaft in Russell district via the Gilpin tramway to the New York mill at Black Hawk, which is under lease to the Pewabic Con. M. Co., of which J. C. Fleschhutz is manager. The Pewabic shaft is down over 400 feet, and it is proposed by the company to sink it down to a depth of 1000 feet, commencing sinking operations soon. They intend to put up a new shaft building 24x60 feet on the Iron shaft and will build a 36-foot gallows frame and put in an 80 H. P. gear hoist and six-drill air compressor. The Iron shaft is about 600 feet deep, and as soon as it is unwatered sinking will be commenced.——The Mont D'Oro M. & M. Co. is operating in the Quartz Valley district, north of Central City. E. C. Sherman as manager. The company owns the New Century, Smuggler and Felix claims and have a lease and bond on the Delight and Colorado Girl. Operations are being carried on with tunnel workings. The main tunnel has been driven on the Delight vein.

At Central City the new Lombard shaft house of the Yankee Con. M., M. & T. Co. is ready for operations. H. I. Seemann of Denver is superintending work.

Gunnison County.

The Golden Islet M. & M. Co., operating the Cortland mine, in McIntyre gulch, near Ohio City, is taking out good ore. The shaft is down 300 feet. The company has leased the Jersey Blue mill, above Ohio City, and has been treating the low-grade product for several weeks. The dump ore runs .28 of an ounce in gold, 14 ounces in silver and 7% lead. Twelve tons are being put into one and the concentrates have a value of 3.92 ounces in gold, 101.32 ounces in silver, besides the lead values, showing a loss of but $1.99 per ton in the tailings.

The Lost Delusion, in Dutch gulch, near Bowerman, owned by J. Wey, is ready to ship high-grade ore.—— E. C. Staller has good ore in the Fraction lode, near Bowerman.——At Bowerman the Eureka, owned and operated by G. Morris, is showing free gold ore.

Lake County.

Work has been resumed this week on the Applegate group in Willis gulch, near Twin Lakes, with E. Morehead as manager. The main prospecting tunnel will be driven to tap the veins located on the surface. —— B. F. Magness has started work on the Silver Serpent property on Twin Peaks mountains, near Twin Lakes.

At the Bertha mine on Breece hill, Cripple Creek, preparations are being made to unwater the shaft so that the lower or sulphide zone can be worked. The shaft is 530 feet deep with 200 feet of water in it. When the shaft is unwatered drifting will be started. In the upper workings the property is shipping twenty-five tons daily of a good grade of siliceous ore.——The work during the winter on the Highland Chief on Breece hill has been done through a tunnel and shipments have been steady. Vernier & Shipley have decided to clean out the old shaft, which is 225 feet deep, and sink another lift. —— On the Curran and Grand Prize, adjoining the Highland Chief, a tunnel has been driven 500 feet, but the ore channel has not been found. The lessees have decided that they are above the ore and will sink a winze, starting 160 feet from the portal of the tunnel.——T. D. Kyle, leasing on the Fannie Rawlins, is shipping 100 tons per month of an excellent grade of siliceous ore.

The Sedalia, in Big Evans gulch, near Leadville, is sinking the shaft with three shifts to a depth of 950 feet. —— The Great Hopes, in Big Evans gulch, will resume sinking the shaft.

Larimer County.

At Pearl the Swede mine is being worked under the management of H. A. Brown.——The Zirkel mine at Pearl is to be started after two years' idleness.——The Big Horn shaft, near Pearl, is being unwatered preparatory to examination and sampling.

Ouray County.

It is reported that the Saratoga mill, near Ironton, is to be torn down so that a smelter can be put on the site. W. J. Sawyer has charge of the mill.——The Thistledown M. & M. Co. intends to put in an electric power plant and compressor and drills to drive the development tunnel on Mount Hayden.——M. L. Thistle of Ouray is manager.——The Treasury Tunnel M. & M. Co. will add twenty stamps to its mill at Red Mountain. W. J. Hammond is manager.

Saguache County.

Mrs. G. H. Adams has appointed H. A. Lee consulting engineer of the Baca grant, near Creston, and has decided to open the entire mineral section to lessees.——The Independence mine has a 100-stamp mill which will be opened to custom work.

San Juan County.

The Gold Tunnel & Railway Co., Wm. Cole superintendent, is working the Highland Mary mine, in Cunningham gulch, near Silverton.

The Bon Homme mine, in Burrows park, near Animas Forks, is to be worked, since all litigation has been settled. It is reported that men will be put to work during July and that heavier machinery will replace the present equipment.

San Miguel County.

The Smuggler-Union mill at Telluride has seventy stamps dropping on ore from leasers. The cyanide plant is treating 175 tons daily.——The Black Bear M. Co. plans to put up a 20-stamp concentration plant on land near Telluride leased from the Smuggler-Union Co. A 2½-mile tram from mine to mill will be built. G. C. Wagner of Telluride is general manager.

Teller County.

(Special Correspondence).—A few years ago the operators in Cripple Creek district united in building a railroad for the transportation of the ores from that district to avoid the excessive rates being charged at the time by the railroad doing business in the camp. Since then they have, to a certain extent, disposed of their holdings in the new road. It is now rumored that a merger has been made with all the roads entering the district and it is feared that the former excessive rates will be restored. To overcome this it is understood a suit is to be instituted against the railroads to prevent the merger and thereby prevent a raise in the rates. With the big drainage tunnel to be built and the railroad merger a probability, it is not a pleasant situation for the operators in Cripple Creek to contemplate. But from the manner in which they have handled their affairs in the past it is believed they will be equal to the task of settling things satisfactory to themselves.

Cripple Creek, July 11.

Superintendent C. C. Jackson has struck a vein in a lateral from the bottom of the shaft of the Mary Nevin, between Beacon and Rosebud hills, Cripple Creek. —— Murphy & Co. have discontinued sinking at a depth of 350 feet in the Monte Cristo mine on Beacon hill, Cripple Creek. —— An air compressor is to be put in at the Maloney workings of the Empire State by Crowder, Thompson & Co. of Cripple Creek.

The Fortuna shaft at Victor is to be sunk 300 feet deeper.——The Fort Pitt Co., working the Sunshine property on Galena hill, Cripple Creek, will sink the shaft from the 400 to the 700-foot level.——The lessees in the Battle Mountain of the Rose Nicol Co. of Cripple Creek are drifting on the 450-foot level.

Lessee W. O. Burnside and associates, who are operating under lease the Lonaconing property belonging to the El Paso Co. on Beacon hill, have opened up a large body of ore on the 300-foot level. —— The Mollie Kathleen property on Tenderfoot hill, Cripple Creek, is to be prospected by H. D. Gortner.

The output for the first six months of 1905 foots up to $10,858,695. The output by months is as follows:

	Tons.	Valuation.
January	63,800	$1,891,300
February	48,800	1,687,000
March	57,700	1,827,680
April	57,900	1,863,300
May	59,115	1,884,215
June	58,500	1,725,200
Totals	345,815	$10,858,695

The dividends of the public companies for the first six months of the year amount to $1,619,540.

The report of Stratton's Independence, Ltd., at Cripple Creek shows how the company has benefited by the leasing system. The report covers a period from July, 1904, to April, 1905, inclusive, leasing being started last July. Since that period three dividends have been declared, amounting to £75,000. During the ten months of operation a total of 42,555 tons were shipped out, which gave a net profit to the company of £89,967. Besides paying the three dividends, the company has a balance of cash of £49,600 in the treasury. In the report it is stated that compared with the results and reports published for the last financial year the change brought about under the leasing system inaugurated a year ago is remarkable. The ore during the ten months has run a little over two ounces to the ton. The richest ore came from the upper levels of the mine. Every level from No. 1 to No. 9, inclusive, produced ore of much higher grade than heretofore, and this output of ore has not only been a result of extensions in the old workings, but also from the exploration in fresh ground. Development work under the supervision of C. M. Becker from August, 1904, to March, 1905, amounted to 6261 lineal feet. It further states that the sulphide vein struck in the western portion of their ground on the sixth, seventh and eighth levels is an entirely new discovery to the mine, and it is said to be a most promising one. The vein averages 4 feet in width and it costs about 80 cents per ton to mine. Pumping was suspended in June of last year, when the water rose from the 1400-foot level to within a few feet of the 900-foot level. Lately, however, the water is lowering in consequence of drainage operations, and lessees are now driving a drift at a depth of 560 feet, taking out considerable good grade ore near their northern boundary line.

IDAHO.

Blaine County.

The equipment of the Minnie Moore mine and mill at Hailey has been turned over to Lyttleton Price, Jr., the superintendent, who has taken a contract to do 2000 feet of exploration work upon the 1000-foot level. The stopes have been leased to J. J. Donovan, who is to pay all expenses and to pay a royalty of 20% of the smelter returns.

Idaho County.

The 200-foot crosscut tunnel on the Columbia of the Gold Bug-Columbia, near Elk City, is to be run 500 feet farther.

The Thunder Mountain Gold Reef Co. has decided to put in a 30-ton mill and cyanide plant at its property near Warren.

The Atlas M. Co. are timbering their mine in the wet places, but the mill will not be run until definite plans can be made. Geo. T. Crane of Spokane, Wash., says that the saving on the plates is so low that it will be necessary to add a cyanide plant.

Owyhee County.

C. W. Hill has secured the option on the Stormy Hill, War Eagle, and purchased the El Madhi and Ninety-Two, and has located the Carton, all near Silver City.—— It is reported that the management of the DeLamar mines at DeLamar is having plans made to have the mill remodeled. It was first constructed as an amalgamating mill, and then, after many changes had been made, converted into a cyanide mill. —— The Sinker Tunnel people are running a crosscut, west, from the 600-foot level of the upraise, 400 feet to prospect for veins west of the Elmore Chariot. —— J. E. Masters of Silver City has started work on the Tybo-Blue Bird mines in Pixley basin.

Shoshone County.

In a recent account of the Cœur d'Alene district, F. L. Ransome says that the chief lead-silver ore producers are the Federal M. & S. Co., operating the Tiger-Poorman mine at Burke; the Mammoth mine at Mace and the Last Chance mine at Wardner; the Bunker Hill & Sullivan M. & C. Co. at Wardner; Larson & Greenough, owning the Morning mine, near Mullan; the Hercules M. Co., owning the Hercules mine, and the Hecla M. Co., owning the Hecla mine, both near Burke. Other mines which have contributed largely to the general production in the past, although they are not at present being worked on the same profitable scale as those just mentioned, are the Helena-Frisco mine, near Gem; the Granite and Custer mines on the west slope of Tiger peak; the Gold Hunter mine, near Mullan; the Sierra Nevada mine, 1 mile west of Wardner, and the Crown Point, owned by the Cœur d'Alene Dev. Co., west of Wardner. The Bunker Hill & Sullivan and the Last Chance mines are both on the same general zone of fissuring and their workings connect at several points. The deepest level, near Wardner, is the Kellogg tunnel of the Bunker Hill & Sullivan mine. This tunnel, which is a crosscut, runs southward from the mill, situated on the South Fork, about a mile west of Kellogg, for a distance of 12,000 feet to the lode. It cuts the latter about 2000 feet below the croppings. The Morning mine has a crosscut adit 2 miles north of Mullan, the ore being brought down to the mill on the South Fork over a narrow gauge railway. A new adit, now being run from the mill, will cut the lodes about 800 feet below the bottom of the present workings. The Gold Hunter mine is also opened by a crosscut adit, from which two lower levels are being worked through a winze. The Tiger-Poorman and the Hecla mines are operated through shafts in the town of Burke. These workings are respectively 1800 and 600 feet deep. The Standard-Mammoth mine has two long crosscut adits, the Campbell tunnel, running nearly north from a point on Canyon creek, below Mace, and the No. 6 tunnel, running nearly northeast from a point on the creek, 3000 feet west and about 150 feet below the Campbell adit. From the end of the Campbell tunnel, an underground shaft or winze gives access to five levels, the lowest being 1050 feet below the adit level, or about 2000 feet below the apex of the vein. The main adit of the Helena-Frisco mine is a south crosscut from Canyon creek, near Gem, at the end of which is a shaft 1400 feet deep, connecting with seven levels. The main adit of the Hercules mine is on Tiger peak, about 1½ mile north of Burke and about 1500 feet above the bed of Canyon creek. The mine as yet produces no concentrates, the crude ore being hauled by wagons to the railroads at Burke.

The Humming Bird Co. will resume work on its mines at Burke, with ten men. Arrangements have been made with the Federal Company for air with which to run its machine drills. D. Hudson, formerly superintendent of the Mammoth mine, will be in charge. The company shut down work a year ago, pending the obtaining of patents to all its holdings. For the present work will be confined to extending the No. 5 crosscut tunnel, which is now in 1900 feet, and to drifting on the two ore chutes already opened in this tunnel.

KANSAS.

The law passed by the Legislature last winter appropriating $410,000 to build an independent oil refinery at Peru has been declared unconstitutional by the State Supreme Court in an opinion rendered by Associate Justice Thompson. The oil refinery law provided for the erection at Peru also of a branch of the State penitentiary to house prisoners, who, it was intended, were to work the oil plant. State Treasurer Kelly and Warden E. B. Jewett, whose duty it was to issue the bonds, declined to sign them in order to first secure a decision on the constitutionality of the act. Attorney General C. C. Colman filed mandamus proceedings in the State Supreme Court on behalf of the State to compel the officers to sign the bonds. The opinion declaring the act to be illegal and unconstitutional was concurred in by all of the members of the Supreme Court.

MICHIGAN.

The fourteen leading producing mines at Lake Superior produced 10,720,000 pounds more of copper in the first half of 1905 than in the first half of 1904 and 13,430,000 pounds more than the first half of 1903. Nine show an increase over both years, four a decrease from both years and one a decrease from last year and increase over 1903. The comparison is as follows:

	1905.	1904.	1903.
Calumet & Hecla	40,550,000	38,900,000	40,100,000
Quincy	10,400,000	8,300,000	8,400,000
Osceola	9,250,000	9,650,000	6,470,000
Tamarack	9,150,000	7,170,000	7,000,000
Champion	8,250,000	5,700,000	5,375,000
Baltic	7,275,000	5,700,000	5,300,000
Trimountain	6,125,000	5,350,000	5,500,000
Mohawk	5,350,000	3,975,000	3,375,000
Wolverine	4,675,000	4,750,000	4,800,000
Franklin	2,300,000	2,525,000	2,750,000
Atlantic	1,700,000	2,700,000	2,800,000
Isle Royale	1,425,000	1,100,000	1,250,000
Mass	1,000,000	1,200,000	1,250,000
Adventure	1,000,000	710,000	650,000
Totals	108,450,000	97,730,000	95,020,000

The largest increase is that of Champion, 45%, the entire Copper Range output for the six months, excluding the half of Champion not owned, was 17,525,000 pounds, or at the rate of 35,000,000 pounds per annum, compared with 13,900,000 for the half of last year, an increase of 26%. Osceola, owing to the explosion and labor troubles, has fallen slightly behind last year, but will this month more than make up the loss. Mohawk has increased 34%, Tamarack 28% and Quincy 25%.

Houghton County.

At No. 1, or the northerly shaft, of the Franklin Junior, near Houghton, sinking has been in progress for some time from the nineteenth level. Drifting from No. 1 shaft is in progress at the seventeenth level northward, at the eighteenth north and south, and at the nineteenth north and south. Stoping is in progress at many points in the drifts tributary to No. 1 shaft, practically all levels below the eleventh, both north and south, having stopes working. No. 2, or the southerly shaft, has completed cutting the plat at the eleventh level and sinking is being resumed at that point. The conglomerate lode continues of the same favorable character with depth that has been manifested since about the fourth level. Drifting is in progress northward at the fifth, sixth and eighth levels and southward at seventh and ninth levels. Drifts have been started both north and south at the tenth and eleventh levels. No. 2 shaft is connected by means of the northerly drifts with No. 1

shaft at the fourth, seventh and ninth levels. The shaft is operating with only its temporary hoisting equipment, whose capacity is limited to a single skip. The Franklin is operating thirty-five drills at the Junior and fifteen drills at the old mine.

MISSOURI.

Jasper County.

The Joplin News-Herald reports that the Cataract M. Co., operating near the Mandarin mine, is a new Joplin producer.——The drill hole being put down south of Columbus is now 1530 feet deep and the drill is in limestone.——Two good drill strikes have been made on the Granby land at Smelter hill by the Granby M. & S. Co. ——It has been costing the Middle West M. Co. $1 an inch to sink a shaft near Joplin.——M. M. Smith and others of Joplin have taken a lease on ten acres of the Holton land, north of Joplin, and will prospect it for ore.——The Hancock M. Co.'s new mill on the Murphy land, south of Fairview cemetery, has been started up. ——J. H. Spencer and B. W. Lyon have taken a lease on forty acres, west of the old Spring City mines, and intends to prospect it.——W. T. Miller of Joplin has the contract to build a 100-ton mill on the Quaker Maid mine at Spurgeon.

The Montecillo mine and mill, near Prosperity, have been sold to R. M. Padgett and J. H. Schund of Chicago. The mine has been owned and operated by T. B. Amsden, T. Sawyer, J. Madeira and Al. Maness.——It is reported that the Sciota mill, on the Missouri Zinc Fields land, near Webb City, is to be remodeled and equipped with a hopper feed. Larger and heavier rolls are to be put in. The property is under the management of C. T. Orr.——The Express M. Co.'s new 100-ton mill at Neck City is nearly finished. The old mill and mine are being operated steadily.

Stone County.

Ten mills will be built in the Baxter Springs district this year, as follows: The Omaha, Perkins, M. K. & T., Ward & Co., Joanna, Dark Horse, Hobo, Boaz & Co., L. L. Wright & Co. and Strong Bow. Boaz & Co. have purchased the Monte Cristo mill at Galena and will remove it to their lease on the Crawfish land. The Hobo is having figures and plans made for a new plant. The Dark Horse mill is already under construction. The Joanna has shut down to build a mill. In addition to the ones mentioned the Mission M. Co. is contemplating a mill similar to the Yellow Dog mill at Webb City.—— Omaha parties have purchased the J. E. Wilson shaft on the Charters land, near Baxter. The shaft is down 47 feet. Machinery is being put in and sinking will continue as rapidly as possible.——The E. L. Wright M. Co. has made a contract which calls for the sinking of five shafts on their lease of the Crawfish land, near Baxter, and the erection of three modern concentrating mills.——The Spring River M. Co., south of the Joanna, is putting in a steam hoist.

MONTANA.

Lewis and Clarke County.

The Montana Electrolytic Reduction Co. has purchased the water plant of the Helena & Livingston Reduction Co., near Corbin, and the reduction works at the same place, where test work will be commenced, while the main plant, to cost $250,000, is being built. It is believed this plant will be located on the site of the Peck concentrator, near Helena.——M. Cavanagh of Helena, who has bonded the Sunrise group, 4 miles south of Helena, has placed men on the property.——The Whitlach M. Co. has sunk to the 500-foot level on the Whitlach-Union property, 4 miles south of Helena, and is cutting a station, from which crosscuts will be run.—— The Brooklyn Bridge Co., represented by Mr. Krueger, which has been developing properties 5 miles south of Helena, has commenced shipments.——M. Manuel of Helena is developing the Minnesota group, near Corbin. ——George Winter, who has a bond and lease on the Mammoth, at Clancy, has begun operations.——Kent & Cummings of Helena have bonded the Union mine, in the Elkhorn district.

Madison County.

Foster & Curran are working the Bull Dog mine, near Silver Star.

Missoula County.

The Monitor mine, near Saltese, is being pumped out preparatory to putting on a large force. Repairs to the road to the mine have been completed and the hauling of ore has commenced.

NEVADA.

Esmeralda County.

The smelter to be built at Sodaville by the Nevada Ore Purchasing, Refining & Smelting Co. is expected to be in operation within ninety days. The machinery, furnace brick, etc., have been shipped from San Francisco and Salt Lake and will soon be on the ground. The estimated cost of the mill is $182,000. It will have a capacity of 250 tons of ore a day and contracts, covering a period of two years, sufficient to keep the smelter running steadily, have been entered into with mine operators of Lida and Sodaville.——Satisfied with the tests that have been made during the last two months at Goldfield, it is reported that the H. L. Frank Co. is having plans and specifications drawn which will result in the construction of eight 5-stamp batteries with concentrators and cyaniding tanks. Power will be taken from the generating plant at Bishop Creek, Cal., but a gasoline auxiliary plant will be built at Goldfield to be used in case of accidents.

Lincoln County.

(Special Correspondence).—A small experiment plant, using the cyanide process, is testing the ores from the Red Cloud mine, 5 miles from Goodsprings. The average extractions have been successful, being 88% of the gold values.——G. Fitzgerald and party, developing gold-copper claims in the Kingston mountains, report high assays.——F. Williams is developing the Hoodoo lead-silver mine, near Sandy.

Sandy, July 11.

From Goodsprings Superintendent H. Hamy of the Chiquita group reports that good ore has been struck.

The Homestake mill at Deerlodge has been started after a complete overhauling and the addition of several new slime tanks. A. Myers has charge. ——Work will be commenced at the Wild Irish - Amethyst in Pike's Diggings by D. F. Kilbourne. S. P. Moore of Provo will be superintendent and G. A. Paxman of Silver City, Utah, will be assayer and metallurgist.

Lyon County.

J. Somers has resumed work at the Ludwig copper mine at Yerington, and will sink the shaft from the 500 to the 600-foot level.

Nye County.

In the double-hand drilling contest at Tonopah, Nev., on July 4, W. Bradshaw and W. R. Ross drilled 40⅝ inches in fifteen minutes. Bradshaw won the single-hand contest with 25⅛ inches.

NEW MEXICO.

Grant County.

The Burro Mountain district centers at Leopold, near Silver City. Here the Burro Mountain Copper Co., under the management of T. W. Carter, is developing copper mines. They have a concentrator of 140 tons daily capacity.——The Whitewater Copper M. Co. is working claims in the Burro mountains under the direction of C. P. Laughlin, president and general manager.——G. M. Sublett and E. G. Mahoney are arranging to start work on the Burro mountain properties, near Silver City.——The Alessendro Copper Co. of Silver City will start up its mines in the Burro mountains. ——The Comanche Co. is preparing to open its mines in the Burro mountains.——In the Bear Mountain district, 9 miles from Silver City, R. F. Clark is developing the Red Cloud mine.——H. S. Spense has returned to Grant county from England, where he interested capital in mines at Steeple Rock upon which development work is to be commenced.

Dona Ana County.

The new double compartment shaft on the Bennett-Stephenson mine at Organ is down 50 feet. It is to be sunk to a depth of 400 feet.

Sierra County.

The Moffitt M. & M. Co. intends to commence work upon mines in Kingston. The company has purchased machinery for a 50-ton plant.——Hillsboro people have organized a company, with J. F. Plemmons as general manager, to work the Palomas Chief mine at Hermosa. ——Ore hoisting has commenced on the 200-foot level of the Empire mine. The ore is being treated at the Bonanza mill.

OREGON.

Baker County.

In the double-handed drilling contest at Sumpter, July 4th, Engle and Henderson from the Platts mine drilled 33⅞ inches in fifteen minutes.

The Psyche mill, near Greenhorn, is running full capacity, ten stamps being run on Psyche ore and ten stamps on ore from the Diadem, an adjoining property. The Psyche has a large amount of ore blocked out, a part of which is of shipping quality and is sent to the Sumpter smelter. The Diadem is being put in shape for work.——The Snow Creek mine, near Diadem, has good ore on the 225-foot level, and the 10-stamp mill is running full time. The buildings that were destroyed by fire last March are being replaced.——The Greenhorn G. M. Co., operating at Worley, had twenty-three tons of its ore worked at the Psyche mill as a test, which gave returns of $18 a ton. A sinking plant has been ordered, which will be put in as quickly as possible. Meanwhile work will be continued on the tunnel level. ——The owners on the Salmon group, near Greenhorn, have decided to run a long crosscut tunnel to tap the ledge opened this winter by a prospect tunnel near the top of the hill. A compressor plant has been ordered. ——The Pyx mine, near Greenhorn, has begun operations under the supervision of C. Parker.——The Gold Coin, near Greenhorn, is being put in shape and will start July 15.——R. Godfrey and F. Conway have leased the Man of War claim, near Greenhorn.

Manager E. W. Messner of the Indiana mine, 28 miles from Baker City, has instructions to put in a heavier mining plant.

Crook County.

Construction of a mercury furnace for the Lookout mountain cinnabar property of the American New Almaden Co. has begun near Prineville.

Douglas County.

The Continental G. M. Co. of Portland have made arrangements to put in a mill at the Continental mine on South Myrtle creek. The lower tunnel is in 800 feet on the vein. Manager W. B. Stewart has charge.

On the Yellow Jewell, near Nugget, Superintendent Armitage has been sinking from the tunnel level.

Grant County.

Manager W. W. Gibbs, of the Copperopolis, near Prairie City, has the new concentrating plant ready for work. The plant consists of a rock breaker, Wild crusher, two concentrating tables and jigs, with 25 H. P. gasoline engine.——The Dixie Meadows, at Quartzburg, is making regular shipment of concentrates.

Operations in the Bull of the Woods, under direction of Superintendent E. P. Kennedy of the Badger Company at Susanville, have been opened this spring. Ten stamps were put in the Badger plant last winter for the Bull of the Woods.

Jackson County.

The Bliss mine, 3 miles south of Gold Hill, is being developed by the Bill Nye M. Co., who are driving a tunnel to tap the vein and also sinking a double-compartment shaft. Manager Andrus and Treasurer F. C. Bellamy are at the mine.

Josephine County.

The Overland M. Co. at Cable Cove is working a full force in good ore on the 250-foot level. The company has decided to place reduction machinery at the mine this summer. Secretary J. Fortin of Minneapolis is at the mine.

The Argo M. Co. has just finished a 5-stamp mill at its mine on the Galice creek, near Grants Pass. For the present it is only run on a day shift, but in a short time a night shift will be put on. The mill is operated by water power from Snake creek.——The Van Dorn copper property, at the mouth of Big Pickett creek, on Rogue river, near Grants Pass, has been bonded by the Golden M. Co.

SOUTH DAKOTA.

Custer County.

At the Clara Bell mine, 10 miles from Custer, work will be begun on a 10-stamp mill and cyanide plant.

Lawrence County.

The Hidden Fortune Co. at Lead temporarily stopped milling at its plant on the last day of June, as the ore on the south end of the property, mined near the surface, contained too much mud and mine work was too expensive on account of the wet weather. The mud could not be separated from the ore; it was necessary to pay freight on this worthless material, and when it was at the mill an excess of slimes gave trouble and annoyance. The company is considering leasing its mill.

Pennington County.

A crusher has been put in at the Golden West mill, near Rochford, by Manager E. J. Kennedy.

UTAH.

(Special Correspondence).—Mining operations in Utah are improving each month. With the big drainage tunnel once more in operation in Park City it will mean considerable to that district, as many of the mines depend to a large extent on this tunnel draining their ground, enabling them to work to a greater depth without pumping. It is understood the Keith-Kearns Co. will build a large mill near their mines to handle the ore from their property.——In the Tintic district the shipments have been greater than for several years past. The rates now being made by the smelters enable several of the low-grade mines to work at a profit. At Eureka especially a great deal of new work is being done and old abandoned mines being reopened. Robinson and Mammoth also show increased activity. In the southern part of the Tintic district, at Silver City, but very little is being done at present, but it is understood several of the properties will soon be operating. In this end of the district they encounter considerable water, which is rather expensive to handle.——The operators in the Mercur district are beginning to realize that the mines are not worked out, as heretofore reported, but that they are opening new ore bodies as development work progresses. In this district is found a large body of quicksilver ore, which is being made to pay the owners. It is also found that the old tailings dumps from some of the mills can be made to pay, and as a result the dumps are being put through the mill.——But little work is being done at present in the Sunshine district, although no good reason can be assigned for the district not being as prosperous as some of its neighboring camps. It is rumored that some of the properties will soon be in operation. —— Much work is being done at Kimberly, 200 miles south of Salt Lake City. The Annie Laurie Co., which is the principal mine of the district, has opened up another tunnel which promises to keep them in ore for several years, and it is understood the old mill will either be enlarged or a new one built to handle the ore from the mine. The Sevier Con. G. M. & P. Co. is also doing development work and preparing to erect a new mill.——In the Stockton, Binhgam and Newhouse districts everything is progressing as rapidly as possible. ——Generally speaking, the mining camps of Utah are in first-class condition, with the prospect of being much better in the future. With another large smelter about to be erected it will give the mines of Utah a good outlet for their ore.

Salt Lake City, July 11.

Juab County

The Raymond-Illinois mine is being put into condition to start work. Manager J. C. Sullivan will start operations on the 1500-foot level of the workings of the Raymond in both the north and south drifts.——J. Eustice recently shipped ore from the Emma Jane claims, 3 miles west of Eureka.——T. F. Singiser of Salt Lake, who has a bond and lease on the West Mammoth and Golden Ray property, will have a wagon road built to the mine from Eureka. Work has been commenced under the superintendency of W. Mathews, and the hoist and machinery now in use at the American Flag mine at Park City will be put on the property to sink the shaft.——The McKinley M. Co.'s tunnel is in 644 feet.

In the double-handed rock drilling contest at Eureka on July 4th, E. Lewis and J. Mingerotti drilled 37½ inches. J. Mingerotti won the single-hand contest by drilling 20⅝ inches.

Piute County.

The stockholders of the Sevier Con. M. Co., with properties in the Gold Mountain district, besides electing a board of directors, gave authority to this board to enlarge the company's present milling facilities. While the mill that has been in use at the mine has been doing satisfactory work, it is not large enough, as it was built for experimental purposes. Practically a complete new plant is to be built which will enable the treatment of 100 tons of ore per day. The officers for the next year are: S. W. Tulloch, Washington, D. C., president; W. E. Maison, Ogden, Utah, vice-president; E. H. Thorton, Ogden, treasurer. P. H. Maison was chosen as secretary and R. W. Foster, manager.

M. Krotki and J. F. Lyon have started a new tunnel on their iron property, north of Marysvale.

Salt Lake County.

In the double-handed drilling contest at Bingham on July 4th, T. Brady from the Yampa mine and W. Tasker from the Highland Boy drilled 31⅝ inches. In single-handed drilling, E. Thomas drilled 13⅝ inches.

The Beck tunnel of the Boston Con. is in 860 feet. The Ben Hur No. 1, the Ben Hur No. 2 and the Metropolitan tunnels have been started.

The Butler-Liberal M. Co. of Bingham state that their drain tunnel is 1542 feet long, 6 feet wide and 8 feet in height. In order to secure sufficient dump room they have run a single-compartment raise, with a manway and ore chute from the tunnel level to the surface, a distance of 237 feet. The Hart tunnel is in 364 feet.

J. M. Boutwell, in a recent Government report, says

that Bingham is the leading copper producing camp in Utah. The copper shipments are made up almost entirely of sulphide ores, in which low-grade primary sulphides, massive chalcopyrite and pyrite predominate. The grade is raised, however, by secondary black copper sulphides, including chalcocite, tetrahedrite and tenorite. Some argentiferous lead ores, mainly galena, are also shipped regularly. The copper ores yield accessory gold, silver and iron; the argentiferous lead ores, accessory copper. The copper content in the average sulphide ores is low, ranging from 2½% to 4½%; but the accessory gold, averaging from 10c to $1, and silver averaging from two to five ounces, raise the value of the ore. Zinc blende occurs in the argentiferous lead ores, but is not saved. The copper ores occur in large masses in metamorphosed limestone, and also in grains disseminated through monzonitic intrusives. The large bodies lie within massive marbleized limestones adjacent to intrusives and fissures. Associated with this ore in the coarsely crystalline marbleized limestone are the following minerals: Garnet, epidote, tremolite, sphalerite, specularite, pyrrhotite, etc. The ore bodies are in the form of lenticular beds lying roughly parallel with the bedding of the country rock, and exhibit a massive banded structure which is continuous with the bedding of the inclosing country rock. These beds are localized into elongated lenticular shoots which dip roughly with the bedding and pitch moderately. These shoots sometimes assume great size, being several hundred feet in length along their strike, nearly 200 feet thick, and have been followed downward continuously for several hundred feet. The disseminated auriferous copper ore occurs throughout extensive stocks of monzonite, but particularly in areas where it is fractured, fissured and altered. Irregular grains of chalcopyrite and cupriferous pyrite are there found in small veinlets, intergrown with secondary silica, sericite, etc., chiefly along joint or fracture planes, and subordinately in altered areas immediately adjacent to such planes. Definite shoots have not been proved. The argentiferous lead ores occur in veins filling fissures which trend northeast - southwest and traverse all kinds of rocks known in the district. The veins are widest in limestone and in shales which contain calcareous and carbonaceous matter. Their general structure is a rough banding parallel to the walls of the fissures, but these bands are not sharply defined, the minerals of one band being irregularly intergrown with those of adjoining bands. The relative distribution of minerals in these bands indicates that the general order of deposition from older to younger was sphalerite and tetrahedrite, pyrite, and galena, calcite, quartz, rhodochrosite, and barite.

Sevier County.

Work is to be resumed at the Perjue-Surprise claim at Richfield.

Summit County.

The Daly-Judge mill at Park City is likely to start up Aug. 1 and 200 men will be put to work in the mine.—— At the New York Bonanza mine, at Park City, work is being prosecuted on the 500, 600 and 700 levels.

WASHINGTON.

Clallam County.

According to R. Arnold, placer gold mining has been carried on since 1894 in the beach sands at different points along the west Washington coast, from about 10 to 23 miles south of Cape Flattery. During this period at least $15,000 has been taken from the district. The gold is derived from the Pleistocene sands and gravels, which cap the bluffs along this portion of the coast, being concentrated on or near the bedrock at the base of the bluffs by the action of the waves. The gold is accompanied by small amounts of platinum and iridosmine, the three being associated with magnetite and "ruby" (garnet) sand and small quantities of pyrite. Mining is carried on principally by the sluice box method, although where the water supply is limited, as at the locality 2 miles north of the mouth of the Ozette, rockers are used.

Stevens County.

During the last five months the Young America mine, near Bossburg, has shipped silver and lead ore to the value of $2000, says M. E. Jesseph of Spokane. The mine is worked by tunnel, the main tunnel being in 300 feet. The shaft is down 35 feet and will be continued to the 100-foot level.

FOREIGN.

AUSTRALIA.

Bendigo.

At the Catherine Reef United, Bendigo, a rich reef has been discovered at 2200 feet.

New South Wales.

Delprat's shaft of the Broken Hill Proprietary mine has been sunk to the 1020 level, and has been connected to the 800 and 1000 levels, and all the ore from these levels is now hauled through this shaft. All the stopes in the mine are well filled, most of the mullock being obtained as before—from the open cuts—but the tailings from the zinc plant are now used largely. The "crosscut" system of stoping in the heavy block ground at the 650 level, Block 12, has answered admirably, and no trouble has been experienced since this method has been adopted. The ore body discovered at the 800 level in Block 11 in 1903 by a diamond drill has continued to open up well, and is yielding good supplies of ore. No traces of the fire of 1902 were noticed, but to ensure thorough ventilation a large Capell fan, capable of handling 80,000 cubic feet per minute, has been put in underground with beneficial results. The permanent condensing plant has been running throughout the year with great success, and the old plant erected during the water famine is still working satisfactorily on the extraction engines. Three ball mills have been added to the ore dressing plant, and the electric motor continues to work well, handling the tailings on the dump. Superheaters have been added to the boilers, and automatic chain grate stokers are being put in. The salt cake plant originally built for handling 1000 tons of zinc tailings per week has been completed and enlarged, and is now in regular operation. In actual work, after certain modifications were effected, it proved equal to, and is at present treating, about 3500 tons of material weekly. The tailings of this plant, containing practically no metal, are sent underground for filling, and prove not only more economical, but also provide a superior material for packing the worked out ground, the filling being much closer than with ordinary mullock. The manufacture of sulphuric acid by the Carmichael-Bradford process has been elaborated since its establishment, and a second chamber of 100x20x20 feet added, and a third is in course of erection, together with Guy-Lussac and Glover towers. To the end of the year the company produced 470 tons of chamber acid, which is used for the manufacture of salt cake.

Queensland.

At a meeting of the directors of the Light of Day Prospecting Co., at Mount Morgan, it was decided to accept the offer of the Goldfields' Diamond Drilling Co. to bore 1000 feet at £1 1s. per foot. Mr. Sandstedt, who conducted all the drilling for the Mount Morgan G. M. Co., will have charge of the boring. The drilling operations at the Light of Day property, being next to the freehold of the Mount Morgan Co., will be watched with interest.

An official report says that the Hodgkinson gold field is almost deserted, many of the miners having gone to prospect for wolfram and molybdenite. The mines now working are the Hodgkinson, General Grant, Vulcan & Britannia, New Monarch, Homeward Bound, Southern Cross, Tyrconnel and Resolute and Home Rule mine at Woodville. The Cecil Syndicate recently put up a cyanide plant, which is now working. They are making preparations to put in a 20-head battery on their own mine. When the mill is finished the Cecil Syndicate will employ 100 men. The New Monarch is being worked by tributers, and since taking up the mine they have made £6 to £8 per man per week.

CANADA.

BRITISH COLUMBIA.

Boundary District.

Boundary mines shipped in week ending July 8 as follows: Granby mines to Granby smelter, 13,018 tons; Mother Lode to British Columbia C. Co.'s smelter, 3776; Mountain Rose to British Columbia C. Co.'s smelter, 132; Oro Denoro to Granby smelter, 66; Providence to Trail smelter, 60. Total for week, 17,052 tons. Total for year, 476,473 tons. Following is the smelter treatment for the last week: Granby smelter, 13,250 tons; British Columbia C. Co.'s smelter, 3865. Total for week, 17,115 tons. Total for year to date, 487,965 tons.

Nanaimo District.

The Puget Sound Iron Co. has given a lease to Pittsburg men to work a part of the iron deposits on Texada island.

Nelson District.

G. O. Buchanan, lead bounty commissioner, reports for the fiscal year ended June 30 that the total lead production of Kootenay has been 55,752,019 pounds; 11,000 tons have been exported; the remainder, nearly 17,000 tons, has been smelted in British Columbia. The rate of bounty paid varies with the London price of lead, and is less for exported lead than for lead treated locally; $10 a ton in the first case, $15 in the second. He estimates that the total bounty to be paid will be about $340,000 out of the $500,000 set aside by the Government for this purpose.

Rossland District.

The Le Roi experimental concentrating plant has sent its first shipment of concentrates to the smelter. The test plant is to be kept in steady operation and the management reports that the process is operating in a satisfactory manner.——The winze driven on the main ledge of the Center Star has reached a depth of 190 feet below the ninth level and sinking has ceased. The next step will be the deepening of the shaft from the ninth level, which is to be commenced immediately.——The ore shoot found on the 1350-foot level and which extends down to the 1550-foot level of the Le Roi continues to be developed. A station is being cut at the 1550-foot level for the purpose of drifting along the shoot at that depth. The development of this shoot is most important.——Following are the shipments for the week ended July 8: Le Roi, 2000 tons; Le Roi, crushed, 150; Center Star, 2370; War Eagle, 1200; Le Roi No. 2, 260; crushed, 1400; Jumbo, 300; Spitzee, 150. Total for the week, 7630 tons; and for the year to date, 175,528.

Slocan District.

The Argenta wagon road has been completed. It is understood the Argenta Mines, Ltd., will put in a compressor and mill. There is some likelihood of the Lavina group, near Argenta, being worked.——The Silver Star M. Co., P. Maris of Kaslo, manager, is working twenty men at the Cork mill, which is running on ore from the Cork mine.

Vancouver Island.

On Howe Sound, 28 miles from Vancouver, the Britannia Copper Syndicate have completed the power plant and aerial tramway. The mines are 3 miles from the beach and consist of large bodies of auriferous and argentiferous copper ore developed by tunnels. A 21,000-foot Riblet aerial tramway, designed to handle 2400 tons of ore per day, connect the mine with the concentrating and shipping plant on the beach. The buckets have a capacity of 1000 pounds each. A direct current electric surface railway hauls the concentrates from the concentration buildings to the shipping bins at the wharf, and delivers timbers and supplies to the aerial tramway, a 35-ton capacity Westinghouse electric locomotive being used. The generating plant in the power house at the beach consists of two 250-kilowatt alternating current 3-phase Westinghouse generators, coupled to Pelton water wheels. A 250-volt direct current generator furnishes power for the direct current surface electric tramway. The alternating current will be used to run the aerial tramway motors, concentrator and crushing mill motors and for lighting. Water for power is brought 2⅝ miles from Britannia creek under a high head of 1600 feet. Each lengt of the steel pipe has been tested to withstand a hydraulic pressure of 1800 pounds to the square inch. W. Meredith is superintendent of the engineering and electrical equipment, and Mr. Carmichael general superintendent of construction for the Britannia Copper Syndicate.

CHINA.

The Far Eastern Review says that with the completion of the railway to Taokou, the coal deposits of Shansi and Honan will find an outlet to the coast. Since the work of Von Richthofen thirty years ago, it has been known that both anthracite and bituminous coal occurred in these provinces. Recently the Peking Syndicate has been engaged in their development. The new railway line, in connection with the Wei river and the Grand Canal, will make it possible to deliver the coal to Tien-Tsin at prices much below present charges for imported fuel. It is expected that the freight on railway and canal will amount to $2.45 per ton, while the cost of mining is estimated at from 25 to 60 cents. The present price for good European coal on the coast ranges from $7.25 to $9.75 per ton. The Peking-Hangkow Railway, now being constructed through the coal fields, will shortly afford a second outlet by means of the Yangtse river. When the necessary connections are completed, coal can be delivered to Nanking for about $2 45 per ton, and to Shanghai, which imports about 1,000,000 tons annually, for little more. The known coal fields of China are estimated to extend over 400,000 square miles. So far development has been altogether for local trade. The Kaiping, which extends for 20 miles along the Tien-Tsin-Newchwang Railway, is, on the whole, the best developed. It is said that in this field there are 60,000,000 tons in sight. In China the winters are severe, and, if cheap coal is available, people will buy it. At present only the wealthy can afford coal. At Po-tou, 468 miles from Wei Hai, anthracite coal from the Chinghwa mines is sold for $24.50 per ton, whereas with improved transport it should be sold for one-fifth of that price, at a profit of about $2.45 per ton. The numerous navigable waterways connecting with the Wei river and the Grand Canal will afford cheap transportation to a large, densely populated area. Shansi is said to be rich in iron ore, which occurs in the Coal Measures, and the local iron industry has also been developed. It seems likely that with the development of the fields and facilities of transportation, manufacturing industries of various kinds will be developed.

MEXICO.

Durango.

It is reported that the smelter of the American-Mexico M. & D. Co. at San Lorenzo will soon be increased in capacity, as an order has been placed for a 200-ton copper furnace. At present the smelter is running full capacity with its 100-ton copper furnace. A tramway is to be built from the mines to the smelter.

Chihuahua.

The Calera M. Co. is shipping zinc ore to Pueblo, Colo., from its Calera mine, 12 miles from Minaca. The company recently completed a narrow gauge railroad from the Chihuahua & Pacific's Guerrero Valley Extension to the mine. It is developed for zinc alone.

Jalisco

The San Rafael mines in the Parnaso district has been sold to H. H. Sawyer and associates of Philadelphia, Pa. —— The Paloma M. Co. has been organized in Springfield, Ill., to develop copper-silver mines near San Antonio de los Moran in Ayutla district. The company was promoted by J. Breckenridge, who will have the management. The company expects to put in reduction machinery.

Guerrero

The 200-ton experimental smelter of La Dicha M. Co. at Acapulco is almost finished. The survey and grading of the railroad from the mines to San Marquez has been completed.——The Guardena M. Co. is putting up a 16-stamp mill near Cayuca de Catalan.——J. G. Moylan contemplates putting in a power plant on the San Cristobal river for the Poder de Dios mine near San Cristobal.——The San Mateo mine near Taxco is being unwatered by E. du B. Lukis.——A concentrator is planned for the La Delfina mine at Chichihualcos.

Mexico.

The San Rafael Amparo and the Prestacion mines at Sultepec, which were abandoned by the Arcos Co. because of water, are to be unwatered and worked by a company being organized by J. B. Phipps.——Work has been resumed at La Quimaca mine at Sultepec by Compania Minera German Roth y Cia and at the Munoz by Telesforo Garcia.——At the Maria de Oro mine, near Morelos, a cyanide plant has been put in by J. R. Ambrosius.

Sonora.

The Monte Vista G. & S. M. Co. is preparing to start work 15 miles east of Cos station and 65 miles southeast of Douglas, Ariz., under the superintendency of C. E. Hanson, formerly of Wicox, Ariz.

RUSSIA.

According to Naphtha, the entire Russian production of crude oil in meter centners in 1904 and 1903 was:

	1903.	1904.
Balachany	14,520,893	13,437,728
Sabuntschy	37,746,063	35,515,554
Romany	19,646 706	21,917,995
Bibi Ejbat	25,764,022	29,670,958
Binagady	42,309	49,875
Totals	97,719,993	100.592,110

Production of naphtha from flowing wells in meter centners:

	1903.	1904.
Balachany	.....	.....
Sabuntschy	493,710	879,606
Romany	2,151,218	1,392,284
Bibi Ejbat	6,120,829	3,661,782
Binagady	.....	.....
Totals	8,765,757	5,933,671

Production of naphtha in pumping wells in meter centners:

	1903.	1904.
Balachany	14,520,893	13,437,728
Sabuntschy	37,252,346	34,635,948
Romany	17.495,478	20,525,713
Bibi Ejbat	19,643,224	26,010,776
Binagady	42,310	49,874
Totals	88,954,111	93,658,439

Commercial Paragraphs.

THE Abner Doble Co. of San Francisco, Cal., have the contract for the machinery for an addition to the hydro-electric plant of the Cramer Electric Co.

BULLETIN No. 2003 from the Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York, gives further information regarding the "Little Jap" hammer drill.

THE Iler Rock Drill Manufacturing Co. has been organized, capital $100,000, to manufacture the Iler drill. Officers: F. M. Iler, president; A. U. Magnan, secretary; F. C. Mulvaney, vice-president. Place of business, 1325 Blake street, Denver, Colo.

Obituary.

GILBERT JOHNSON, mining engineer with the Trinity Copper Co. at Kennett, Shasta county, Cal., was killed July 6, by a Mexican while surveying for the company in Mexico.

D. W. BALCH, for many years engaged in mining and mill work on the Comstock Lode of Nevada and the Mother Lode of California, died July 3d at Honolulu, H. I.

GEORGE STRAUGHAN, once manager of the Winterpeck mine in West Virginia, and interested in mines in Nevada and California, died recently in San Francisco, Cal., age 73 years.

Latest Market Reports.

SAN FRANCISCO, July 14, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27 5/16d (standard ounce, 925 fine); New York, bar silver, 59¼c, refined (1000 fine); San Francisco, 59¼c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.00; Lake, 1 to 3 casks, $15.00@15.25; Electrolytic, 1 to 3 casks, $15.00; Casting, 1 to 3 casks, $14.50@14.75. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £66 spot per ton.

The copper market remains unchanged, with a good healthy condition all around. Production is not influenced by any unusual conditions and the demand is normal. There is a slight gain in the visible supply, a noticeable feature during each summer, when isolated mines which are restricted more or less in their operations during winter months can work uninterruptedly. It is said that the domestic consumption is rather lighter than might be expected, but that shipments to China are very heavy, and no cause for these heavy importations of the metal by the Chinese has been assigned. Some believe that this heavy buying is for delivery to others through China, presumably Japan, but there is no confirmation of this idea.

Following are the figures of the German consumption of foreign copper for the months of January to May, 1905, compared with the same period of time for 1904 and 1903:

	1905.	1904.	1903.
Imports, tons	42,744	47,231	36,223
Exports, tons	5,324	3,239	4,739
Consumption, tons	37,420	43,992	31,484

Out of the above, 35,882 tons were imported from the United States.

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.12½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £13 11s 3d ℔ long ton.

SPELTER.—New York, $5.40; St. Louis, $5.80; London, £24 2s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $31.25@31.50; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, ℔ lb., 35@37½c. London, £143.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $19.50 ℔ Troy oz. Platinum ware, 75@82c ℔ gram.

QUICKSILVER.—New York, $39.00@$40.00, large lots; London, £7 7s 6d; San Francisco, local, $38.00@38.00 ℔ flask of 75 lbs.; Denver, $45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.75c; San Francisco, Plumbers', 100-lb. lots, 17.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.60; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $23.00@$23.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lbs. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ℔ set; 14 oz., 40s., 9¾c.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¼@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 62c; cs., 67c; raw, bbl., 60c; cs., 65c; Lucol oil, boiled, bbl., 54c; cs., 59c; raw-bbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

MOLYBDENUM.—Best, $2.75 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

URANIUM.—Oxide, ℔ lb., $3.50.

MERCURY.—Bichloride, ℔ lb., 77c.

TUNGSTEN.—Best, ℔ lb., $1.25.

PHOSPHORUS.—American, ℔ lb., 70c.

SODIUM.—Metal, ℔ lb., 50c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MAGNESIUM.—Pure, N. Y., $1.60.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

HOSE COUPLING.—No. 793,869. July 4, 1905. Andrew H. Anderson, Kellogg, Idaho. This invention relates to a device which is designed for the detachable coupling of hose or like conductors. It consists of a house-coupling having two abutting sections of substantially equal diameter, a head upon one section chambered to receive the opposing end and having inwardly projecting pins, slots in the other sections, into which the pins are slidable, collars fixed upon said slotted sections, a sleeve slidable between the collars and having inwardly projecting pins, slots upon the head of the other section into which said pins are slidable, said slots having circumferential extensions into which the pins of the sleeve are turnable to lock the coupling.

FLY-PAPER HOLDER.—No. 793,871. July 4, 1905. Julius H. Bien, San Francisco, Cal. This invention relates to a holder for sticky fly-paper. Its object is to provide a holder for sticky fly-paper which will prevent the adhesive from running off the paper, protect the hands in handling the paper, allow the paper to be stood on edge or held at an angle when in use, enable the paper to be folded and pressed tight together into a small compass for packing and shipping purposes, and which will operate to exclude moisture from the paper when stored in stock. It consists in the combination with a sheet of sticky fly-paper of a flexible backing therefor having sides and end flaps adapted to be folded over and united directly to the sticky edges of the sheet of fly-paper and forming a non-adhesive border around the same, the side flaps of said border having central incisions as to permit the sheet and backing to be folded in book form.

FRICTION CLUTCH. — No. 793,927. July 4, 1905. William H. Fulcher, Oakland, Cal. This invention relates to a clutch mechanism designed to readily unite or disengage revoluble parts. It consists of a plurality of circular segments forming one member of the clutch, an exterior shell forming the other member, and mechanism by which the said segments are simultaneously expanded within the shell to produce the grip and unite the two members or correspondingly contracted to release the grip and allow either member to be moved separately. Its object is to provide a clutch which is especially designed for the driving of machinery of any description and particularly such machinery as is operated under heavy stresses.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JULY 4, 1905.

793,869.—HOSE COUPLING—A. H. Anderson, Kellogg, Idaho.
794,071.—SURVEYING INSTRUMENT—J. Barbon, Portland, Or.
793,633.—BOAT—J. W. Beall, Laton, Cal.
793,817.—TRACTION ENGINE—J. H. Beckner, Seattle, Wash.
793,871.—FLY-PAPER HOLDER—J. H. Bien, San Francisco.
794,141.—FOLDING STEP—J. S. Coxey, Aberdeen, Wash.
793,820.—TELEPHONE—N. E. Damico, Redlands, Cal.
793,827.—RAILWAY SIGNAL—H. M. Davenport, Long Beach, Cal.
793,828.—SHELF—W. L. Dunn, Buckhorn, Cal.
793,829.—WALL STRUCTURE—A. W. Eager, Los Angeles, Cal.
793,830.—GAS GENERATOR—Eichler & Becker, San Francisco.
793,927.—FRICTION CLUTCH—W. H. Fulcher, Oakland, Cal.
793,722.—CURRENT MOTOR—P. Henrichs, Clarkston, Wash.
794,110.—FRUIT GATHERER—C. Hertz, San Francisco.
793,839.—RAISIN STEMMER—J. T. Latta, Selma, Cal.
793,845.—TELEPHONE—F. B. Long, Los Angeles, Cal.
794,151.—ADHESIVE DEVICE—R. C. Lowry, Seattle, Wash.
793,728.—BINDING STRIPS—B. F. Mackall, San Francisco.
793,673.—FOLDING CHAIR—F. T. B. Mann, San Diego, Cal.
793,795.—BRIQUETS—H. E. Marsh, Los Angeles, Cal.
793,889.—VALVE—J. C. Martin, Jr., San Francisco
793,797.—FORMING GLASS—D. Murray, Seattle, Wash.
794,119.—HOE—A. Richardson, Milton, Or.
793,690.—COUPLING—K. P. Snyder, Pasadena, Cal.
793,862.—SASH CLOSER—A. C. Van Doren, Seattle, Wash.

Dividend Notice.

Mutual Savings Bank of San Francisco,
710 MARKET STREET

For the half year ending June 30, 1905, a dividend has been declared at the rate of three and one-quarter (3¼) per cent on all deposits, compounded semi-annually and free of taxes, payable on and after Saturday, July 1, 1905.

GEO. A. STORY, Cashier.

Dividend Notice.

SAVINGS AND LOAN SOCIETY,
101 MONTGOMERY ST. COR OF SUTTER.

Has declared a dividend for the term ending June 30, 1905, at the rate of three and one-half (3½) per cent per annum on all deposits, free of taxes, payable on and after Saturday, July 1, 1905.

EDWIN BONNELL, Asst. Cashier.

Dividend Notice.

SECURITY SAVINGS BANK,
316 MONTGOMERY ST.

For the half year ending June 30, 1905, dividends upon all deposits at the rate of three and one-quarter (3¼) per cent per annum, free of taxes, will be payable on and after July 1, 1905.

FRED W. RAY, Secretary.

Dividend Notice.

THE CENTRAL TRUST COMPANY OF CALIFORNIA,
42 Montgomery Street, Cor. of Sutter.

For the half year ending June 30, 1905, a dividend has been declared on the deposits in the savings department of this bank, as follows: On term deposits at the rate of 3 6-10 per cent per annum, and on ordinary deposits at the rate of 3¼ per cent per annum, free of taxes, payable on and after Saturday, July 1, 1905. FRANK J. SYMMES, President.

Dividend Notice.

DEBENTURE SURETY COMPANY, RIALTO Bldg., Cor. Mission and New Montgomery Sts., San Francisco, Cal., has declared a monthly dividend for June (No. 26) of five (5) cents per share on its issued capital stock, which will be paid at the office of the company July 10, 1905.

Dividend Notice.

A dividend at the rate of ten (10) per cent per annum has this day been declared upon the capital stock of THE FIRST NATIONAL BANK OF SAN FRANCISCO, CAL., for the six months ending June 30, 1905, payable on the 10th instant. Transfer journal will be closed on the 7th and 8th instants.

JAMES K. LYNCH, Cashier.

San Francisco, July 5, 1905.

FULLY ONE HALF

the price paid for high-priced FANCY PACKING is wasted. There is none better than "EUREKA"—few, if any, so good—and it is but about ONE-HALF the price. Every dealer will furnish it. Be sure though to name GENUINE "EUREKA."

ROBERTSON - THOMPSON INDICATOR

tells at once if engine is doing its duty, and how to correct the trouble. They are moderate in price.

WILLIS PLANIMETER.
VICTOR REDUCING WHEEL.
HINE STEAM SEPARATOR.

JAS. L. ROBERTSON & SONS, 195 Fulton St., New York.

MINING AND SCIENTIFIC PRESS.

Whole No. 2348.— VOLUME XCI. Number 4. SAN FRANCISCO, CAL., SATURDAY, JULY 22, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

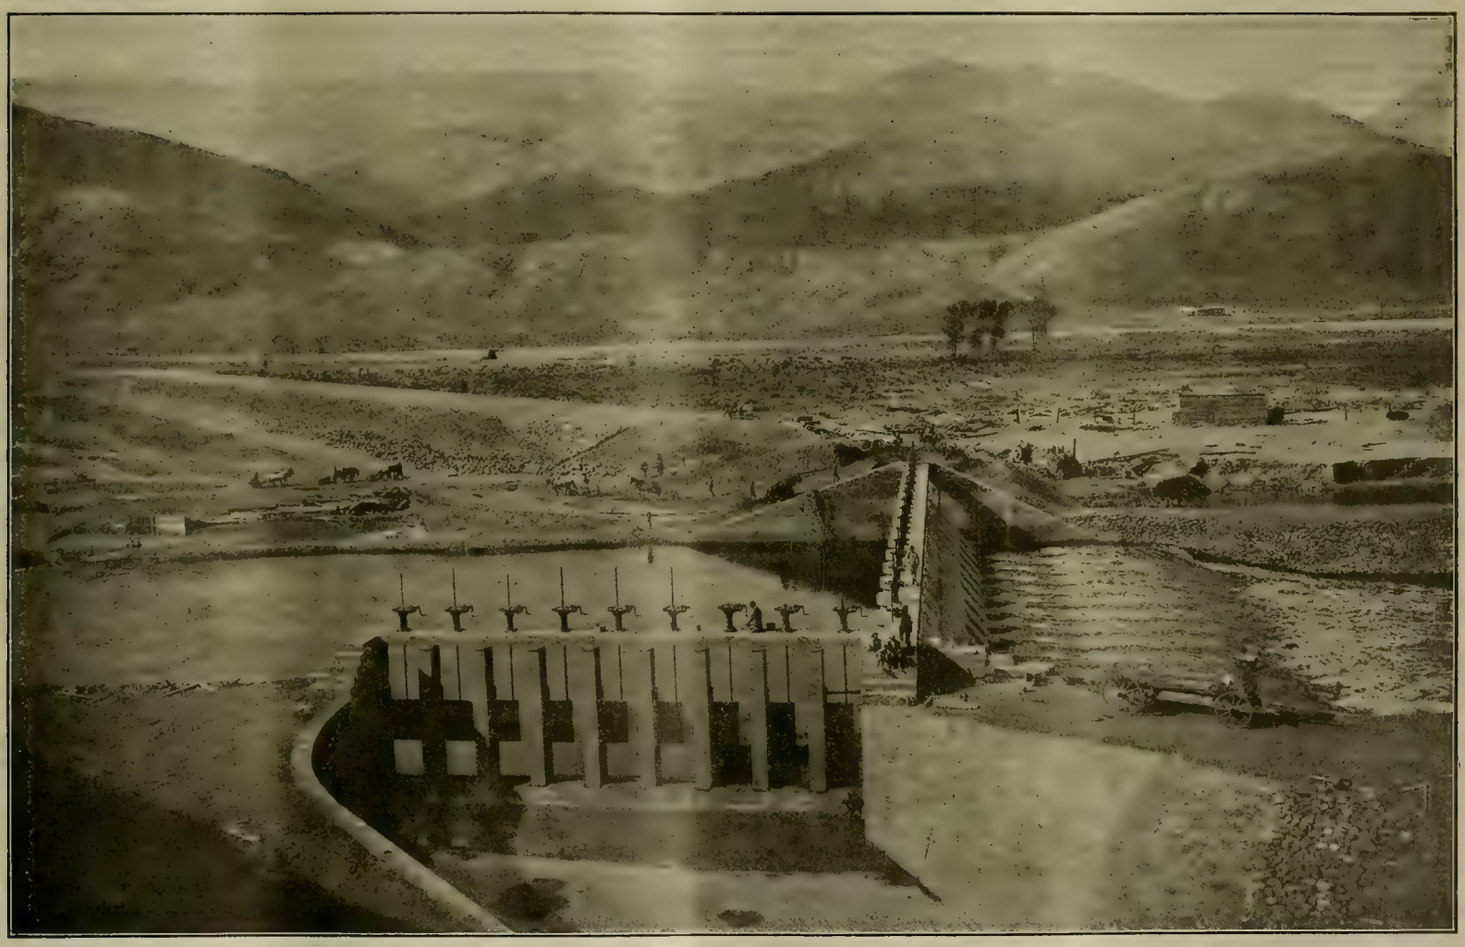
Value of Geological Knowledge.

A knowledge of geology is as essential as a knowledge of mining methods themselves. There are many expert miners who are capable of handling difficult undertakings in mining work and who can carry that work to a successful termination; but all good miners are not geologists, and a lack of a knowledge of even the rudiments of structural geology on the part of a mine manager or superintendent has not infrequently cost mining companies large sums of money. One curious fact in connection with such cases is found in the sublime confidence the miner places in his own judgment when lacking this essential training. He does not know much, if anything, of geology, but he is not aware how much he lacks in this, and, when such is the case, he probably never will know it. There are abundant illustrations of the necessity for geological knowledge, as well as a practical knowledge of mining. The mine superintendent who ran a long tunnel and then sunk a shaft in black clay slate, thinking it was coal, is an exaggerated example of this sort of miner; but he is little worse than he who ran a tunnel to reach a flat shoot of ore which cropped out on the surface in a later and unconformable formation. When he failed to find the ore, he sunk a winze and did a great deal of crosscutting in search of the vein, which, of course, he never found. A third mine superintendent started a shaft in the debris of the hillside in which occurred a quantity of float. The shaft was started lower than the apex of the vein, and, as the vein pitched into the hill, he never found the ore body. In another instance the mine superintendent started a shaft on the top of a rounded hill, fully 100 feet higher than the collar of the shaft of a mine half a mile distant. In the latter shaft a rich, flat ore body was encountered at 200 feet from the surface. The first-mentioned shaft was sunk 300 feet and nothing of value found. The reason was at once apparent to anyone having even rudimentary knowledge of geology—the collar of the shaft, though higher than its neighbor, topographically, was about 400 feet lower on the geological horizon, owing to a fault which passed between the two shafts. These are only a few of the mistakes made by first-class miners owing to their having little or no knowledge of geology. More serious errors than any of those here mentioned have been made, and those of lesser importance are of daily occurrence.

It is not enough to study ore deposits within themselves, but to also acquire a general knowledge of stratigraphical geology and the relation of ore deposits to the formation in which they occur, and also the dynamic and structural conditions affecting the deposit since its formation, each of which is important, and a knowledge of these conditions is as essential to success as experience in breaking rock and handling men.

The Detection of Salting.

A great deal of space is devoted by mining journals and the transactions of technical societies to methods of mine sampling. The engineers who are called upon to sample mining properties have various ideas on this important subject, but any of those laid down on common sense lines will give satisfactory results, if the necessary care be taken. It would be quite as interesting if the engineers would give some of the details of methods employed to prevent salting, or to detect the fraud if it is attempted. In some cases the mines are salted, and so deftly is this done that the sampler would not suspect it. There is always the likelihood that the experienced engineer will first make a new rock exposure and cut a channel for his sample that has not been reached by the salter. In most instances successful salting has been accomplished after the samples have been broken down and sacked. Where a large number of samples are taken, it is a physical impossibility for the engineer to keep these samples with him. He must find a secure place in which to put them, pending the final grinding down, quartering and assaying. It is in this supposedly secure place that the salting is sometimes accomplished, and it is to guard against this, or, in fact, any tampering with the samples at any period of the operation, that an absolutely dependable method is desired by the engineering fraternity. Different engineers have their own methods for detecting salting, and of providing checks against salting; some of these are ingenious, and some of them afford a false security. The plan mostly depended upon is that of personal surveillance of the sampling and of the samples from the time they are broken down upon the canvas.



The Dam and Gates on the Truckee River, Nevada. (See Page 61.)

THE discovery of a new diamond-bearing pipe or crater in South Africa is announced. Diamond mining has now been successfully carried on there for thirty-five years, and at one time, several years ago, it had become the generally accepted belief that no new deposits or pipes of diamonds would be found. Within the past ten years there have been a number of important new discoveries, and still others are being made. This latest discovery was made in prospecting for coal and is but one of several recent diamond discoveries made in the same manner by means of bore holes.

THE mine owners of the Cripple Creek region of Colorado are again experiencing a great deal of trouble with ore thieves, and the complaint is made that there are unprincipled assayers in the district who buy the stolen ores. The chief difficulty in the prosecution of these cases has always been, not only in Cripple Creek, but in high-grade districts elsewhere, that the plaintiffs were unable usually to prove the identity of the ore. It will be remembered that ten years or more ago a similar condition prevailed in the Cripple Creek district, at which time a number of assay offices, supposed to be recipients of stolen ores, were dynamited.

Wholesale Location in Alaska.

For several years past complaints have come from Alaska concerning the wholesale location of mining claims by agents in that Territory without any assessment work being performed. Alaska, being without a legislative body, the mineral lands are taken up and held under the Federal statutes. The miners, presumably, may make local laws governing the location of mining claims, not in conflict with United States laws, and fix a minimum amount of work to be performed within a stipulated time as a part of the act of location. The several States have this privilege, and some of them have wisely enacted laws of this character. The several State courts, and United States Supreme Court as well, have recognized the force of laws and rules made by the miners of local organized mining districts as well as the State laws, and there seems a remedy for the existing condition in Alaska, where a few men locate large tracts of land for non-residents, but perform no work upon these locations. Judge Wickersham, of the Fairbanks district, has made a ruling requiring a bona fide discovery as a precedent to location, but this ruling, while seemingly sufficient to meet the exigencies of the case, really goes no further than the requirements of the Federal statutes, and the remedy appears to lie in local rules made by the organized miners of the several districts.

The Cost of Mining.

In statements made by mine superintendents in official reports and elsewhere, unless the conditions under which these costs obtain are stated in such a manner as to be fully understood by one unfamiliar with the situation, the figures are of little use for the purpose of comparison with costs in other places. Each mine superintendent or manager aims to make his mining costs as low as possible. Some give the fullest possible information, but the reports of others are more vague and ambiguous. If taken as stated, without careful analysis, the figures often impress the reader with the economy which has evidently been practiced at the mine in question. For instance, the cost of shaft sinking in an itemized statement is apparently $40 per foot, when some important details, such as the cost of supplying air to drills, cost of repairing drills and expense of power in hoisting, have been omitted. These items added may bring the cost up several dollars per foot. In driving a drift, the same thing is sometimes noticed. Machine drills are used, good progress is made and the expense is surprisingly low, but, on analyzing the expense account, no charge for power for air compressor is made, which will raise the cost substantially. To appreciate the cost of mining per foot, or per ton, requires a definite knowledge of every factor which has an influence on the cost of the work. Among these are the cost of power, of whatsoever kind, and its efficiency, cost of labor and supplies, character of the ground, ventilation of the mine and its cost, and so on through every item of expense, including general expense, which is often omitted, for the reason that this is charged up under some particular department, which is not connected with the operation in question.

It is always interesting to know the cost of mining and milling at any particular place, but this knowledge has no real significance as applied to some other place, unless it be known that the two places being compared are very similar when viewed from a general standpoint.

In a certain district a superintendent of an operating mine was asked the cost of sinking a three-compartment inclined shaft at his mine. He said he could sink such a shaft for $45 per foot, and had actually done so. This placed another superintendent in his neighborhood in rather a bad light, for the second man had stated that he considered $65 a reasonable figure for sinking a three-compartment shaft on a mine within a mile of that managed by the other. This discrepancy was wholly due to the fact that no explanation of the sort of shaft contemplated was offered.

The fact was that the first had sunk an inclined shaft on a soft fissure at something less than $45 per foot, and the second based his estimate on sinking the shaft in the hard country rock. In either case the respective figures given were approximately correct, but without detailed knowledge of the situation it is as impossible to judge of the relative merit of an expense account of mining operations as it would be to estimate the cost of any undertaking of the kind in ground entirely unknown.

Nothing exemplifies this statement better than the fact that conservative mining companies, whose affairs are in the hands of excellent and experienced managers, sometimes set aside stated sums to perform some particular operation, such as driving a tunnel or sinking a shaft, and find that their calculations were entirely at fault, and that owing to unseen and unanticipated conditions, the expense is far greater than was provided for.

When a piece of mining work is done the expense sheet should show every detail under which the work was accomplished. Included in this should be stated the number of men employed in the various tasks; whether machines were used or not, and how many; the size and kind of machine; air pressure at the drill; number and depth of holes drilled; time drilling, and amount of powder used. The progress made daily under these conditions gives a fair idea to an experienced man of the character of the rock passed through, though he may never have seen the place. The method of cleaning up after blasting and the number of men employed in the work also will give an idea of how efficient this class of labor is. Tramming, or transportation by other means, requires attention, and the framing and placing of timbers is an item often of importance, for rock hard enough to justify the use of machine drills does not always stand well after breaking. Superintendence, incidental and general expenses must be included.

These are some of the items of cost in mining, which, when followed out on this line and are faithfully and wholly given, form a valuable means of information as to the cost of mining work, and they may be used to advantage in the conduct of similar operations elsewhere. Statements of mining cost which do not include such itemized details are merely interesting in a general way without being of particular value.

Shaft sinking on the Rand in South Africa has been reduced to a science and some phenomenal work has been accomplished there; but no one will claim that there are not as good and capable mining engineers in America as there are on the Rand—indeed, some of the best and fastest work accomplished on the Rand has been under the direction of Americans; but no one has ever heard of a large shaft being sunk and timbered in America at the rate of 230 feet per month. This has been accomplished in the Rand, and every miner knows that there must be some great advantage in the physical conditions on the Rand to make this high rate of speed possible. And yet, strange as it may appear, with the rapid rate of progress, with the cheap Kafir and coolie labor on the Rand, the cost of sinking these deep shafts is much higher per foot than work on shafts of similar size and depth in the United States. What these South African shafts lose in direct cost is, however, more than offset by the speed and time saved, which reduces the interest charge on capital invested.

Cost of Transportation.

Many of the mines of the northern Black Hills, South Dakota, are so situated that it has been found necessary to place their mills at a distance, often of several miles, from the mines, the ore being hauled by the railroad companies to the mills of the several companies or to custom mills. An official report recently issued by the Dakota Mining & Milling Company shows that, although the property was vigorously worked and the mill kept employed, the heavy cost of mining, transportation and milling absorbed all the revenue derived from these operations, the transportation costs being an important item of this expense.

The company's mines are at Bald Mountain and the 30-stamp, wet-crushing cyanide mill at Deadwood, about 8 miles from the mines. The ores are worth nominally about $5 per ton, and, considering the good showing of profit made by some other similar mines where the ore is no better, but where the transportation problem is not a factor, the company owning the mills at the mines, it is evident in the case of the Dakota Company that the railroads are the only ones who derive a substantial benefit from the operation of this mine. There are several mills in Deadwood which treat ore from the mines at Bald mountain and Terry's peak, and, unless lower rates of transportation are made, it is said all of these mills must close. Water is scarce in the Bald mountain and Terry's peak region, these mountains being at the highest part of the drainage area, and it is therefore inexpedient to place the mills at the mines. There are instances of record where mining companies similarly situated constructed a local railroad and have hauled their ore a distance of 6 miles—nearly as far as in the case above cited—for 12 cents per ton. In the Dakota case it should not exceed 20 cents on a road owned by the company—that is, for the actual expense of ore transportation. Interest on the cost of the railroad and the expense of keeping up the road would increase the cost somewhat; but even so it would be far less expensive than it is at present. The Homestake Company fully demonstrated the value of owning its own narrow-gauge railroad more than twenty years ago. When a proposition of this character is too large for a single company to undertake, the combination of several neighboring companies for the purpose is not by any means a new idea. There is usually a way to circumvent extortionate charges for any service, and combination is usually the best means of accomplishing the desired end. A somewhat similar state of affairs is threatened in Cripple Creek, Colo., where it is now reported the several transportation companies are about to combine their interests.

CONCENTRATES.

WHEN copper is strongly heated before the blowpipe, the flame assumes a green color, which serves to distinguish the presence of that metal from others.

♣♣♣♣

ABOUT 700 tons of tin-bearing ore concentrated at Tinton, South Dakota, produced eight tons of cassiterite. This is equivalent to about $4.75 per ton of ore treated.

♣♣♣♣

CRYSTALS of baryta are comparatively rare, although crystallized baryta is common enough. All quartz is crystalline, but all quartz does not occur in the form of crystals.

♣♣♣♣

ORDINARILY ores which have been roasted concentrate more readily than raw ores, as all the minerals present lose in weight by the roasting, excepting gold and silver.

♣♣♣♣

A COPPER SULPHIDE ORE which also contains zinc blende can usually be successfully treated so that the zinc may be separated from the copper and iron by electro-magnetic separators.

♣♣♣♣

SULPHUR is contraband in time of war, and a neutral power cannot furnish sulphur to either belligerent nation. The uses for sulphur are increasing. In the United States sulphur is made from pyrite, about 50% of sulphur used in the United States being from this source.

♣♣♣♣

IT would not be advisable to build the cyanide plant on a mine dump, or other fill, as it is almost certain to settle and cause much trouble, particularly should the tanks overflow, or the ground become wet from any cause. Tanks must always be provided with a secure foundation, and this can not be found on a fill.

♣♣♣♣

ORDINARILY no use is made of the power developed on a brake incline or gravity tramway, the energy thus developed being offset by the brakes. A certain amount of power may be derived from the excess energy developed by the downward loaded car, which may be taken from the shaft of the drum at the head of the tramway.

♣♣♣♣

AN attempt to smelt raw concentrates with hot blast was made at Anaconda, Mont., some time since, but the idea was abandoned. A 35% matte was produced, but this was too low-grade for converting at Anaconda. By resmelting, the grade of matte was raised to 45%, but elimination of the iron was not further affected by means of the hot blast.

♣♣♣♣

A SERIES of drops in the apron plates of a stamp battery is generally acknowledged a good thing. The drops or steps should not exceed ½ inch in height, or the falling sands will have a tendency to scour the plates. Shaking amalgamating plates are also often of service in saving particles of amalgam on gold which become detached and are likely to be carried away by the flow of pulp.

♣♣♣♣

WHERE the vein outcrops 500 feet higher than the proposed tunnel site, and the slope angle of the hill is 30° and the distance on the slope 1000 feet, it will require a tunnel 866 feet long to reach a point under the croppings, and if the vein dips into the hill at a uniform angle of 60°, it will be cut by driving the tunnel 288.65 feet farther, or a total of 1154.65 feet. This will reach the vein 577.3 feet deep on the dip.

♣♣♣♣

WHERE the vein is wide and is stoped from wall to wall and will stand in large stopes without timbering, filling should be run in before the size of the excavation proceeds too far, as there is danger of collapse if the stope becomes too large, there being a limit to the extent that ore may be removed. The work of mining should be so planned as to make the filling of such stopes easy of accomplishment and at little expense.

♣♣♣♣

THE metallurgy of zinc is of comparatively recent origin. For several centuries prior to 1700 the metal was known, but it appears to have been rather the result of accidental reduction from some of its ores, rather than the outcome of method. Zinc was first reduced commercially at Bristol, England, about the middle of the 18th century, where it was distilled from its ore smithsonite. The normal ore is sphalerite, commonly called zincblende, blende and blackjack.

♣♣♣♣

LOOSE earth when piled in an embankment invariably shrinks, the shrinkage being from 3% to 15% dependent upon the character of the material in the embankment. The liability to shrinkage is reduced somewhat if the embankment be built in thin layers, placed one above the other. Rock dumps shrink in the same manner, but in a somewhat less degree than loose earth. All embankments built in dry weather shrink more than those built during wet weather, or of wet material.

♣♣♣♣

WHETHER a proposed shaft shall be an incline or vertical is a matter which the existing conditions should determine. If the vein dips at 50° or less, it is usually better to sink an incline either on the vein or in the foot wall country rock. For permanency and the minimum trouble in the future the foot wall shaft is most desirable, and is advisable under almost any conditions, while in some instances it is foolhardy to sink it elsewhere. For veins of high inclination a vertical shaft in the hanging wall is proper.

♣♣♣♣

A CUBIC FOOT of quartz weighs about 165 pounds, and a cubic foot of quartz sand weighs about 100 pounds. A sand which has not been sized—that is, sand of approximately uniform size of grains—weighs less than a natural sand in which the grains are of many sizes, as in the latter the smaller grains help to fill the interstitial spaces. A cubic foot of moist sand will weigh somewhat less than a cubic foot of the same sand when dry, but a sand that is perfectly wet and the voids full of water weighs more than the sand when dry.

♣♣♣♣

QUARTZ does not act as a cementing material for granite. Silica often is deposited in fragmental and other rocks, and then acts as a cementing material, of which the recrystallization of quartz grains in quartzite is the best example. By this process a quartzose sandstone becomes a dense quartz rock, to which the name quartzite has been given. Slates and schists are frequently rendered highly siliceous by the infiltration of silica. In some instances the silica replaces some original constituent, such as feldspar or calcite.

♣♣♣♣

SO far as known to "Concentrates," there is no "divining rod" or other reliable device for the discovery of veins of gold, copper and silver, and any one making a claim that he has an instrument by the use of which he can find veins and distinguish between veins of the various kinds of metal, is presuming on the credulity of those giving attention to such representations. An instrument known as the dipping needle has been used for years in locating hidden deposits of iron ore. Magnetite strongly influences the dipping needle, which is similar to the ordinary magnetic needle of the compass, excepting that it is suspended so as to move vertically instead of horizontally.

♣♣♣♣

THE choice of method of concentration of copper ores by wet or dry methods is partly dependent on physical conditions and partly on cost and the result of the operation. It is comparatively easy to concentrate by hydraulic methods, copper sulphides from a quartzose gangue, or from a kaolinized feldspathic gangue, but to successfully concentrate by this method a low-grade (1% to 2% copper) ore, in which the principal constituents are pyrite, pyrrhotite, zinc and altered magnesian material, is quite another matter. This latter class of ore might be worked in with other and higher grades of ore in the blast furnace, but no success need be anticipated, financially, by treating it otherwise.

♣♣♣♣

BY magmatic separation or differentiation is meant the separation or segregation of certain portions of a molten magma from the mass, upon cooling, thus forming a distinct deposit. Chromic iron in serpentine is an example of this type of ore deposit. So also is the occurrence of masses of magnetite in certain basic rocks, such as peridotites. Metasomatic replacement is an entirely different phenomenon, and may occur ages after the rock, in which the process takes place, was formed. The ore deposits in Leadville, Colo., are a typical example of the replacement of limestone by the sulphides of iron, lead, zinc, copper, etc. The rich ore bodies found in that district are the result of secondary enrichment. Ordinarily where replacement has taken place the normal grade of ore is low.

♣♣♣♣

IN the roasting of a base and complex ore, containing iron sulphide, zinc blende, copper sulphide, arsenic, antimony, etc., numerous chemical changes take place, and these sulphides are mostly converted into sulphates and oxides. Copper sulphide, upon roasting, becomes copper sulphate, when oxygen is present. Thus: $CuS + 4O = CuSO_4$. In roasting ores the copper is partly changed to sulphate and partly to oxide. The iron sulphide acts in the same manner. Zinc will be formed from the sulphide and part of it will be volatilized. Galena is changed into a subsulphide of lead and lead sulphate, and arsenic will be volatilized and a portion will be oxidized and in this latter form combine with metallic bases to form arsenates, and antimony acts in the same manner. In roasting such ores the heat must be low at first, and never very high, for success in further treatment.

♣♣♣♣

THE cause of there being so much iron in the gold bullion cannot be readily explained from the data furnished. It may be due to the use of too much copper sulphate (bluestone) in the pans, though the information given does not state whether bluestone is used at all in the pan. Another possible reason for the presence of this iron may be due to improper cleaning of the amalgam, which would naturally mechanically combine a large amount of fine iron particles ground from the pan bottom and the muller. The amalgam after squeezing through canvas should be placed in a wedgewood mortar and ground with a wedgewood pestle, with the addition of several times the weight of amalgam of clean quicksilver, and a little water to cover the surface. By this means the iron is freed and rises to the surface of the quicksilver, and may be collected by means of a magnet. If these propositions do not explain the presence of the iron in the retorted gold, send full information as to the process of treatment in the pans, stating what chemicals are added, and all the conditions under which the amalgamation is accomplished.

ANNUAL assessment work on unpatented mining claims is not required to be performed in any particular manner, but must be of such a character as to show a substantial evidence of good faith on the part of the claim holder, and not be of such a sort as will give rise to any doubt as to its purpose. The placing of machinery, construction of buildings, tramways, ore bins and chutes and other permanent improvements are all admissible as assessment work, as much as work of excavating in the vein, sinking a shaft, or driving a crosscut tunnel to reach the vein. It is not necessary that the work be done within the lines of the claim, for a tunnel, for instance, may be driven to reach the vein in depth, which has its mouth outside the claim. This work may be done on an adjoining unpatented or a patented mining claim, or on adjoining agricultural land. Work may also be done in one place for the development of several contiguous claims, if it is clearly for the benefit of all the claims.

♣♣♣♣

WHERE manila rope is used in transmitting power the grooves must be carefully turned so as to fit the rope. When the groove has too small an angle for the size of rope employed, the rope is forced down into the groove, creating unnecessary friction. In practice it has been found that a groove having a 45° angle is satisfactory. The rope should not touch the bottom of the groove, and the size of the groove should be such that the center of the rope is somewhat above the lines of contact of the rope with the sides. The angle of the groove remains constant, no matter what the diameter of the rope, though the flat space at the bottom of the groove will vary in width with the diameter of the rope used. The grooves vary in depth as they do in width. A groove suitable to run a 1-inch rope is ½ inch wide just above the bottom, and one suited to a 2-inch rope is 1 inch wide just above the bottom space. Grooves should not only be turned smooth, but should be polished as well to lessen the friction, and also to obviate any tendency on the part of the rough sides of the groove to cut the rope. The inequalities left by the turning tool, though small, are nevertheless sharp, and quickly cut a manila rope, fiber by fiber, until the rope is destroyed. Any imperfection in the wheel casting, such as sand or blow holes, will injure a rope seriously in a short time and should be looked after, and filled with iron cement, if present.

♣♣♣♣

WHEN contemplating the building of an inexpensive dam in a creek, or river, as mountain streams are frequently called, the material of which the bottom of the stream and its banks are composed is a matter of importance. If the bottom be soft and loamy, a dam may be built of logs laid in tiers lengthwise of the stream. The first layer is placed and weighted down with earth or boulders, and the second layer placed on top of the first, but somewhat further up stream, so that from 3 to 6 feet of the first tier projects beyond the second. The third tier is laid still further back, and so continuing until the logs have reached the proper height, when the inner or upper side of the dam is filled in with abundant rocks and earth. At the sides a crib is built into the bank, filled with stones. Another form of dam is that of the crib, filled with stones and earth. The inner slope of dams built of logs, brush, rock and earth should not be greater than 30°—2 in 1—and the outer slope not greater than 75°, but the dam must be so built that it will not undercut from the washing away by the water overflowing the crest of the dam. Dams are often built in a curved form or that of a V, with the point up stream. In small streams a log may sometimes be thrown across the stream and boards driven downward like sheet piling pointed up stream, the earth being piled upon the boards. A dam of this kind can hardly be expected to resist floods, as the planks cannot usually be driven down securely enough to make the construction durable.

♣♣♣♣

THE theory of the lixiviation process for silver ores is based on the fact that silver chloride, antimonate and arsenate are soluble in a solution of hyposulphite of sodium or calcium, and that silver may be precipitated from such solutions by means of calcium or sodium sulphide. Where the ore contains lead in the form of sulphate, this is also soluble and will be precipitated by the same reagents as the silver, but the lead may first be precipitated by means of sodium carbonate as carbonate of lead, and the solution then drawn off and the silver precipitated. An ore of silver, where the values are chiefly chloride or chloro-bromide, which largely breaks up into fines upon being shot down in the mine, may possibly yield a large percentage of its silver values by the lixiviation process without further crushing. Some experiments along these lines should be made, with a view to making a practical test. If the ore will not yield a satisfactorily high percentage in this manner, it should be crushed sufficiently fine, with rolls, without much expense, being already in a comparatively fine state. The percentage of extraction of gold present in the silver ore varies, being higher on low-grade material (less than one ounce gold per ton) than that which is high grade. Where it is necessary to roast ores in a gangue largely calcite, it is better to treat the ores by amalgamation than by hyposulphite solutions, as the caustic lime formed in chloridizing the silver has the effect of reducing a part of the silver to metallic form. Where the ore is naturally chloride, having been reduced to this state by nature, and it occurs in lime, there should be no difficulty, as the lime is in the form of carbonate, and not oxide.

Vein Outcrops.

Written for the MINING AND SCIENTIFIC PRESS.

There is nothing in the development of a mine more interesting, and, at the beginning of a mine's history, of greater importance to the prospector than the outcrop of the mineral deposit or vein. All veins do not reach the surface, and it may therefore be safely assumed that there are many valuable deposits and veins of payable mineral which have not been discovered, and some which never will be discovered, being buried beneath hundreds and, in some cases, thousands of feet of volcanic or other debris. In a region like that cut by the Grand canyon of the Colorado in Arizona, for instance, the mineral veins in the Archæan rocks are covered by from 4000 to 5000 feet of sediments—sandstones, shales and limestones—and excepting those exposed in the canyon and its tributaries, these veins will in all probability remain covered and untouched to the end of time. In northern California, the great gold and copper belts which have been developed for a distance of over 200 miles pass northward beneath the immense lava fields of the Lassen peak and Shasta region.

There are many other instances of this character, but these are mostly beyond the reach of human possibility. It is more particularly to the occurrence of outcrops of veins which actually exist at the surface that attention is here directed.

Many vein outcrops are deceptive, even to the trained student of mining geology, and require careful study and investigation. The accompanying sketches show a number of characteristic outcrops, with a diversity of geological conditions:

Fig. 1 illustrates the occurrence of an outcrop of copper ore in the Black Hills of South Dakota. The ore lies along the footwall of a large reef of quartzite —100 feet in width. The leaching of this low-grade sulphide ore through centuries of time has resulted in the saturation of a superficial zone of the slates on the footwall. This enrichment of the soft porous slates proceeded downward until a flat sheet of quartz was encountered, which, acting like a dam, the solutions penetrated but slightly below it. The surface had the appearance of an immense outcrop of rich copper ore, whereas the ore shoot proper was only a few feet in width in the quartzite.

Fig. 2 is the outcrop of a vein of hard quartzose-silver ore in Montana. The disintegration of the boulder-like outcrop has resulted in the slopes on either side of the vein being covered beneath the fragmental masses of ore, large and small, and gave to the vein the appearance of a huge outcrop, over 100 feet wide, when the vein itself is less than 20 feet in width.

Fig. 3 is a characteristic outcrop on the Homestake vein as it appeared before the great open cut was made at that point. The vein did not outcrop prominently, but occupied rather a slight depression on the hillside at that place, though the erosion was doubtless influenced largely by the harder masses of porphyry in the neighborhood.

Fig. 4 shows a flat sheet of ore, the edge of which is buried beneath a porphyry talus. One unfamiliar with the geology of the region would not suspect the existence of a valuable ore body a few feet beneath the surface. This occurrence is in the Terry peak region, Lawrence county, South Dakota.

Fig. 5 shows the great outcrop of a vein standing 80 feet above the inclosing walls, in San Bernardino county, California. This vein can be seen for miles, and at a distance was mistaken for a great dike.

Fig. 6 is the outcrop of a quartz vein on the desert. The low-lying rolling hills is not a region where the average prospector would expect to find valuable mineral veins, preferring usually the mountain region, but veins occurring under the conditions here illustrated are not uncommon in the desert regions of Western Australia and of the southwestern United States. The boulders of quartz are scattered on either side of the reef, but are mostly buried beneath the earthy debris, making the outcrop obscure and unnoticeable from even a short distance.

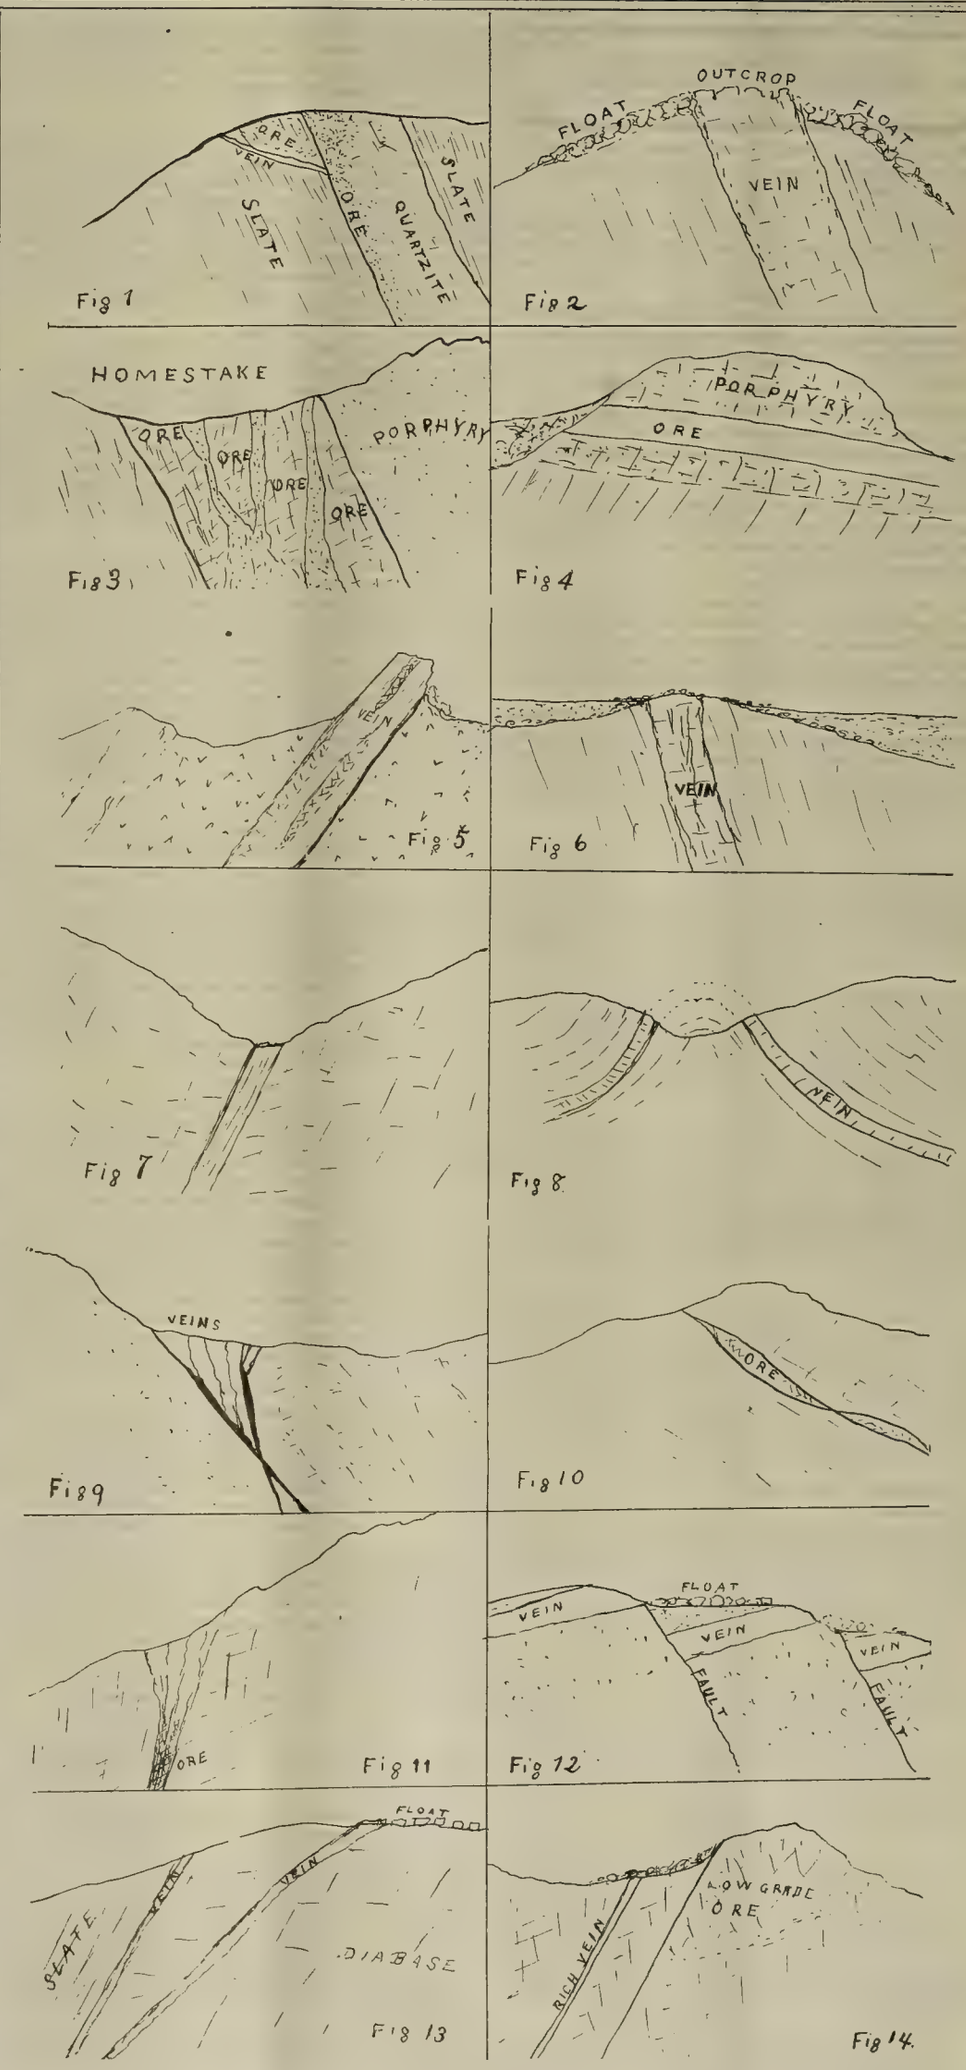
Fig. 7 illustrates the outcrop of a vein in the bottom of a canyon. The vein walls being softer than the surrounding rocks, erosion has cut the canyon down along the course of the vein. This is a very common occurrence in many regions.

Fig. 8 shows a bedded vein duplicated by a fold. This has been taken for two distinct veins; but while it is such as viewed from a legal standpoint, they are of the same origin and formed contemporaneously, but lifted and folded later.

Fig. 9 illustrates the general features of the outcrop of the Comstock lode at Virginia City, Nevada. The footwall dips eastward at about 45°. The hanging wall was shattered by the movement of the rocks and numerous subsidiary fissures were formed in the hanging wall, some of which dip westerly. This, in the early history of the lode, gave some the impression that the vein would dip to the west in depth. A fissuring of the hanging wall of a vein, as in the manner here illustrated, is not of uncommon occurrence.

Fig. 10 shows a valuable ore body which reaches the surface as a mere seam. The only indication here at the outcrop is the softened condition of the country rocks and the occurrence of the oxide of iron. Sometimes a line of springs indicates the proximity of the outcrop of a vein or lode when the outcrop itself is obscured beneath surface debris.

Fig. 11 shows a large and valuable vein of ore



reaching the surface as a system of stringers. No ore is visible, but the place is damp and the country rock—granite—is much decayed. This was the condition at the outcrop of the Bi-Metallic mine, near Phillipsburg, Montana. This condition is duplicated in many places elsewhere.

Fig. 12 shows a curious phenomenon. It was mistaken for the outcrop of a vein of immense width—several hundred feet—and an elaborate report on the extent and possibilities of this huge vein was sent abroad. Nearly half a million dollars in improvements were made as a result. The sketch shows a flat sheet of quartz, 3 to 10 feet thick, faulted several times, with boulders of quartz lying on the segments of granite. To the careless observer it might be mistaken for one immense vein. One person who examined the deposit recognized the fact that it was not a continuous sheet of quartz, but assumed the several repetitions of the same sheet, by faulting, to be the individual outcrops of different veins, and reported twenty-three veins in the property. This phenomenon occurs in Madera county, California.

Fig. 13 illustrates another mistake made where a small vein—2 feet and less in width—was thought to be an outcrop 125 feet wide. The point of real outcrop is seen in the sketch. The detached boulders lying on the surface were thought to represent the width of a large outcrop. After extreme development the true condition was learned.

Fig. 14 illustrates a large mass of low-grade ore which outcrops boldly, while the small accompanying fissure vein of high-grade ore was scarcely noticeable beneath the debris, but was discovered in running a crosscut. This occurrence is in San Bernardino county, California.

In addition to these several instances there are many others that could be added. One, for instance, where a vein was cut by a fault striking nearly with both dip and strike of the vein and causing the latter by displacement to appear to be twice the width it really is at the surface.

There is one condition, however, upon which the prospector may almost universally depend, and that is that there are few veins either great or small, and producing great amounts of gold or silver, that do not show signs of extensive mineralization at the surface, and the same may be said of most copper, lead and quicksilver mines. This mineralization may be merely the kaolinization of the feldspars of the rock walls and a consequent softening of the rock, but in nine instances out of ten the surface along the line of a rich and largely productive vein shows iron oxides, a softening of the country rock and the occurrence of small veinlets of quartz, calcite and iron ore and often a seepage of water, whether the quartz outcrop be prominent or not. Sometimes the quartz outcrop is prominent, but practically valueless, the pay rock being found elsewhere in the vein. In some cases this surface mineralization extends for 1000 feet or more, often very much more, and is from 20 to several hundred feet wide. A great outcrop of quartz is not the most positive sign of a great and valuable mineral deposit or vein, though it is not an infrequent accompaniment.

Goldfield, Nevada, Fire and Explosion.

Goldfield's first serious fire occurred on the 8th inst., as narrated in last week's issue. Herewith are two portrayals of the fire at its height, engraved from photographs received through the courtesy of Mr. Wm. B. Kehoe. Like all great mining camps, such visitation seemed inevitable, and, as it will undoubtedly result in better fire protection, the fire will prove of ultimate benefit to the town. Every mining town has had its big fire, and Goldfield is fortunate if it escapes a more serious conflagration. Already rebuilding has begun and in a few months the fire will be but a memory.

A more serious disaster, so far as loss of life was concerned, took place at Goldfield the day before the fire, when the explosion of a boiler at the Spiking mill resulted in the death of Jas. Spiking and Taylor Bates. The accompanying engraving is from a photograph taken immediately thereafter and graphically depicts the sudden ruin wrought.

Boiler Explosion at Goldfield, Nevada, July 7, 1905.

Fire at Goldfield, Nevada, July 8, 1905.

Fire at Goldfield, Nevada, July 8, 1905.

Ore Sampling.

Henry Louis, in the Transactions of the Institution of Mining and Metallurgy, has the following:

It may be of use to draw attention to a convenient method of sampling either in the field or in the laboratory, which appears to be very little known in this country; I first saw it in use in Sweden and have used it myself a good deal with perfectly satisfactory results. The appliances consist of three troughs, V-shaped in cross section and open at both ends, the angle at the apex being 90°. Dimensions depend upon the material being treated; for field work and large parcels broken say to 1½ inch ring, troughs made of pieces of 10-inch board, 4 feet long, held together by a few nails, answer admirably. For laboratory work I use pieces of stout sheet zinc or tinplate, 12 inches long and 6 inches wide, bent up lengthways, so that each side is 3 inches broad. To use this appliance, one of the V-shaped troughs is placed horizontally, apex upwards on two sheets of canvas, or over two boxes; another trough is placed, apex downwards over the first one, inclining towards it at an angle of 30° or 40°, the lower end resting on the center of the apex of the lower one; the third trough

is placed above the second in zigzag fashion, and similarly inclined, its lower end delivering material at the top end of the second trough. Thus, any material poured down the top trough runs fairly into the second, and then falling on to the apex or edge of the first, is divided into two equal parcels. The operation is very rapid, and may be repeated as often as is required, until the sample is reduced to the requisite size. The appliances are simple in the extreme, may be improvised almost anywhere, and, if the troughs are made of two-hinged pieces, are portable. The few tests that I have made have shown that this simple method seems to be as accurate as any other.

Concentration of Silver-Lead Ores.*

NUMBER II.—CONCLUDED.

Written by V. F. S. Low.

Various methods of sampling the material leaving the mill are in vogue at the present time, but it is often found that samples taken from the trucks with a "spear" are very unreliable. A good system is to sample each truck as it is being tipped and is only part full, and, further, to sample each dump every twenty-four hours. The former assays should be used only for comparison of the work done on the various shifts, but for all official purposes the latter method of sampling should be adopted, as there is much less likelihood of error.

In conclusion, while admitting that there are many points in connection with the subject of concentration which are open for discussion, the writer would state that the practices as set forth in the above brief paper are the outcome of the efforts and experience of the many engineers who have given much of their time and attention to the treatment of the silver-lead ores of the Broken Hill field.

In discussing the paper of V. F. S. Low, F. D. Power said: One would think that any man erecting valuable machinery would take the trouble to see to his foundations, and yet he had seen, in Queensland, the upper stopes of a lode filled in and preparations made on the surface for erecting a winding engine on the top of it. In another case, in Victoria, a battery site was selected on the side of a hill and twelve vanners erected on the ground made from the excavations. As this ground had not settled it was impossible to adjust the vanners, for as soon as they were got right they were thrown out of adjustment by further sinking, and, to make matters worse, the motive power used was a large water wheel, which was also connected with the stamps, so that the rate of work was most irregular. The question of whether it was better to select a site for dressing floors on an incline or on a flat was a moot point. There was much to be said in favor of both, but the matter was generally settled by local conditions. When crushers are placed at the head frames they should be on a separate foundation; if in the head frame itself, as was sometimes seen, they shook the whole structure too much. Sufficient storage capacity for ore on the surface is very important, so as to enable a manager to weather a temporary shortage, due to some accident. When the plant is divided into units not only is there the advantage that only a portion of the plant need close down in case of a breakage or for want of sufficient ore or water for the whole, but, if necessary, ore from different parts of the mine can be treated separately, and experiments might even be carried out with one unit, with the view of ascertaining a better adjustment of the machinery, proportion of water, etc. Seconds should, strictly speaking, consist of particles of ore and gangue combined, which required further reduction in order to separate the ore before it could be concentrated. The remarks about "working back" should be laid to heart by directors and others. It might look very nice on paper to see things balance, but if they were made to balance by working back, the figures were absolutely worthless, and those who relied on them were living in a fool's paradise.

W. Maddern said he had spent some years in the designing and laying out of the largest concentration plant at the Broken Hill Proprietary; and had also recently paid a visit to the Hill when he noted the developments made during his absence. He was also privileged to see the construction of the plant described in the paper. Machines of all kinds had been given their opportunity in the many mills which had followed each other in succession on the Proprietary and other mines, and now they had in the paper under discussion a description of a mill which they could take as a final result to date of all past experience. All the Broken Hill plants differ considerably from what mostly obtain on the Continent and in America. There, classification and grading into several sizes, with separate treatment for each, was more or less resorted to, sometimes making an elaborate system, in order to get the maximum of concentration; but in Broken Hill the commercial aspect was of prime importance in dealing with the large quantities of stuff. It was not so much "What metal can I get out?" as "What will it pay best to get out of the ore?" Consequently, close initial grading had been rejected as so much humbug, and the stuff was rushed through in bulk, leaving the tailings to be subsequently dealt with for zinc recovery. Putting the breaker at the shaft was a very good practice, and one which seemed to be rapidly becoming universal. He noted that instead of the usual perforated percussion feeder from the bin to the rolls, large trommels were being used, the object being, no doubt, to get rid of all the fines possible, to avoid wear on the rolls. He thought that every dry or wet crushing mill, concentrating or otherwise, should be sectioned off. It was very often not possible to apply this to the crushing department, but suitable storage bins effected the same end. In regard to the question of middlings from the tables, there was no doubt that some of the middlings returned more than once in the same way, but he was inclined to agree with the principle of returning the middlings and thus giving them a second chance to get with the concentrates. He thought it paid to do so in the majority of cases. He came across a curious feature about concentrating tables some two years ago in Western Australia. A couple of machines were laid on a timber framing, while others were built on stone foundations. Those on timber gave very poor results, and the cause was attributed to synchronous vibrations. It was decided that stone or brick was the proper thing. However, as machines all over the country were put on timber, it was evident that the case he alluded to was not of frequent occurrence.

The Machine Drill in Mining.*

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS.

As previously stated, one of the most important matters in connection with the successful operation of a machine drill underground is its care. With a good machinist, who not only understands the trade of machinist, but who also knows from experience what a machine drill can actually do, and what some men expect it to do—with such a man in the machine shop, and a careful man to run the drill in the mine, repairs should be comparatively light, and a drill should last a long time.

Each machine should be numbered by file cuts, or otherwise, and the superintendent or foreman should know where each machine is operating during every shift that it is employed, and also who is in charge of it. This idea may not be popular, but it will go a long way toward insuring good treatment for the machine. If a man can abuse and break a machine, take it down, send it to the surface, and substitute another machine, and no one but the drill runner himself and his partner the wiser for it, machines will often be found out of commission—front heads out, back heads broken, flanges knocked off of the shell, and with other aggravating and expensive injuries, evidently the result of carelessness, and no one upon whom the blame may be fixed. With the number system this difficulty is largely obviated. Not only this, but by its use a record of the work actually done by each machine in the mine (as well as by the men), and its cost as compared with the other machines, may be ascertained.

It is bad practice to take a machine apart in a mine. There are a few men running drills who have had sufficient experience in the shop to be able to make any small repairs required, but, even so, in the dark workings of a mine, with the many chances of getting grit into the machine, for losing small parts, etc., it is an unsatisfactory and improper place for taking a machine apart. When a machine is in evident need of the machinist's skill it should be sent to the surface and another machine substituted. It can be more quickly done than the time wasted in trying to fix the machine at the working face. It is perfectly proper to have a suitable place on each level of the mine where such repairs as are necessary may be made by a competent man, but it is more particularly the practice of overhauling machine drills in the drift, shaft or stope that reference is here made.

Each machine or drill crew should be supplied with the necessary wrenches, bars, oil cans and other tools required, and these should be kept in a suitable box near at hand. They will require no crimps, springs, ratchets, pawls or other small parts—these being an inducement to attempt repairs underground. Make the crew responsible for the tools delivered to them, and there will be money as well as unpleasantness saved, for machine men are notorious borrowers of each other's machine tools, and a hunt for a misappropriated wrench or oil can usually costs the company half an hour's time, and often more, every time this incident occurs, which is frequently, if no steps are taken to prevent it.

The machine drill should be well oiled, but it is neither economy nor good sense to pour half a pint or more of oil into a machine at one time. Some men think that all a machine requires is a good liberal dose of oil, and thereafter it will care for itself. If an excess of oil is poured in, the greater part of it will be blown out at the exhaust within five minutes after starting up.

The machine drill is just like any other engine and requires a stated amount of oil, and no more is beneficial, while very much less is detrimental. Some machines are provided with automatic oilers. The machine should be kept carefully packed around the front head so as to reduce air leakage to a minimum. It is not uncommon to find machines leaking badly, and this detracts from the efficiency of the drill more than is supposed.

The pressure of air at the compressor should be high to secure the greatest economy in drilling. There are automatic regulating devices which keep the air pressure at the compressor well within definite limits—90 to 100 pounds per square inch—and sometimes they are regulated to operate within a variation of 5 pounds (95 to 100 pounds). High pressure at the compressor means reduced pressure at the machine, unless the air be reheated intermediately. A rock drill will undoubtedly last a long time if the drill is operated by a careful man and only moderate air pressure is furnished—say 60 to 75 pounds—but the machine will do far less work, for this reduced pressure at the compressor means a still lower pressure at the machine. The drill runs beautifully under comparatively less pressure, but the blows lack force, and headway is consequently slow. It were far better to put on high pressure, and then, employing experienced men, drive ahead as hard as conditions will admit. The bill for expenses and repairs will be higher, but the cost per foot drilled will be noticeably less, and this is the real test of efficiency.

When changing position the drill runner should see to it that the air is shut off, or a serious accident may occur at any moment should the air be accidentally admitted to the drill cylinder. This danger can be obviated by placing a "tee" in the pipe just before the connection with the machine—between the machine and air cock. This tee is fitted with a plug which is easily removed. When the position of the drill is to be changed without disconnecting the hose this plug should be unscrewed. Then, if by any mischance the air cock is opened the air will exhaust through the tee, and no harm is done. Without this simple arrangement, should the air be turned into the cylinder, the piston will be driven violently back and forth, and would seriously injure any one who unfortunately chances to be in the way. Moreover, there is great danger of knocking out the front head, as there is in such cases usually nothing to resist the blows from the piston. In drilling this danger is obviated by keeping the drill bit fed against the rock.

(TO BE CONTINUED.)

Steam Turbine Tests.

Following is a record of tests of operation of the Curtis steam turbine as furnished to E. W. Rice Jr., third vice-president General Electric Co., by the engineers making the test, F. Sargent and L. A. Ferguson:

"We submit herewith the report of tests made on a 2000 K.W. Curtis turbine, made at Schenectady, under our supervision, May 3, 1905, as follows:

"We sent our assistants, Messrs. Clark & Eastman, to Schenectady to prepare the apparatus for making these tests, and they made several preliminary trials before our arrival, and the results of each of the trials very closely approximated the results of the official tests herein mentioned. We had all the instruments carefully tested and standardized during the trials, the electrical instruments being tested by the New York Testing Laboratory in the presence of Mr. Eastman. The surface condenser showed practically no leakage. We took every precaution to satisfy ourselves that the tests were reliable and accurate, and we beg to certify that the results were as follows:

"Full Load Test: Duration of test, 1.25 hour; steam pressure (gauge), 166.3 pounds; back pressure (absolute), 1.49 inch of mercury; superheat, 207° F.; load in kilowatts, 2023.7; steam consumption per kilowatt hour, 15.02 pounds.

"Half Load Test: Duration of test, 0.916 hour; steam pressure (gauge), 170.2 pounds; back pressure (absolute), 1.40 inch of mercury; superheat, 120° F.; load in kilowatts, 1066.7; steam consumption per kilowatt hour, 16.31 pounds.

"Quarter Load Test: Duration of test, 1 hour; steam pressure (gauge), 155.5 pounds; back pressure (absolute), 1.45 inch of mercury; superheat, 204° F.; load in kilowatts, 555; steam consumption per kilowatt hour, 18.09.

"Zero Load Test: Duration of test, 1.33 hour; steam pressure (gauge), 154.5 pounds; back pressure (absolute), 1.85 inch of mercury; superheat, 156° F.; steam consumption per hour, 1510.5 pounds."

THE PROSPECTOR.

The rock from Homestead, Or., marked "No. 4," is a much altered greenstone of the type called by the United States Geological Survey "meta-diabase." It contains some pyrrhotite (magnetic iron sulphide).

The rock sample from Marial, Or., is a silicified eruptive rock, diorite or grano-diorite, and contains on one edge a little fine iron sulphide and a less amount of copper sulphide. The metallic appearance of one face of this specimen is due to pyrite deposited in a seam, and which was subsequently polished slightly by movement of the rocks. The dark green material at the opposite end of the specimen is chlorite.

The Ore Deposits of Mount Lyell.*

NUMBER II.

Written by J. W. GREGORY.

There is little doubt that the great pyritic mass of Mount Lyell is limited in depth. It has been cut off below by a great thrust plane, which brings the conglomerates under the ores and schists, 97 feet below the center of the No. 8 level, which is 755 feet above sea level.

The ores in this ore body are of remarkable purity and uniformity. Peters remarked that in a width of 300 feet across the mass "in the entire distance there is not a piece of gangue rock as large as a walnut." The ores consist almost entirely of iron pyrites containing copper, gold and silver. There is little galena and less sphalerite (zincblende). The only two important minerals forming gangue are quartz and barite.

The most remarkable feature in the Mount Lyell pyrites is the comparative richness of the precious metals. The copper, gold and silver are not uniformly distributed through the pyrites, being less abundant in the ore near the hanging wall, which is in places so poor that it only pays to work as fuel in the pyritic smelting of the richer ores. The ores near the footwall are much richer; thus Peters' assays of a series of samples taken by 2-feet drill holes along the footwall of the southern drive of the No. 3 tunnel varied from 11% to 30% of copper.

The average yield of the mine is about 1000 tons a day. It was at first proposed to limit the open cut to the No. 4 level, above which it was calculated that 693,045 cubic yards or 2,339,000 tons of ore could be obtained by the removal of 1,500,000 cubic yards of the overhanging schists as overburden.

The average composition of the ore which pays to extract is :

Iron	40 30
Silica	4.42
Barium sulphate	2 50
Copper	2.35
Alumina	2.04
Sulphur	46.50

Hence, in spite of the extreme care with which Dr. Peters took the samples, the general richness of the ore is below his estimate; for he excluded the poorer hanging wall portion of the deposit, and based his estimate on samples obtained from the footwall portion, which only was exposed by underground workings at the time of his visit. The richer ore has not proved to be representative of so large a part of the mine as the evidence then suggested.

The mine is by no means equally rich throughout, for the ore on the hanging wall side contains less copper and precious metals than on the eastern or footwall side, and the ore is also, as a rule, richer near the surface than at the deeper levels. Accordingly, for the purpose of estimating the available ore reserves, the mine is divided into five sections, which are numbered from 1–5, from the footwall to the hanging wall side. The three sections (1–3) on the southeastern side of the mine contain the best ore; this has been described as the payable ore, but the limit between the grades of ore which pay to work and those which are useless is of course variable; and now that the ore of the North Lyell mine and the Mount Lyell pyrites can be smelted together, some of the material in the fourth and fifth sections can be used.

Mr. Sticht estimated on March 31, 1901, that above the No. 4 level there was a total tonnage available of 978,337 tons, giving an average value of 2.35% copper, 2 ounces of silver and .0725 ounce of gold to the ton. The two northeastern sections (4 and 5) contained above the No. 4 level 648,328 tons of ore, of which the average assay value is .64% of copper, 1.6 ounce of silver and .06 ounce of gold. The prices of metals at that date were: Copper, £70 per ton; silver, 2s 3d per ounce, and gold, £4 5s per ounce. Value of southeastern ore was estimated at 43s 7d per ton, whereas ore of the second division was only worth 17s 8d per ton.

Between levels Nos. 4 and 5 there was, according to Mr. Sticht's estimates of March, 1901, 1,723,218 tons of ore, and the average assay value of the whole of it was, copper, .64%; silver, 2.15 ounces, and gold, .048 ounce, which at the current prices of the metals was worth 17s 10d per ton. Within these levels there had originally been some masses of much richer ore, which had been entirely worked out before that date. Below levels Nos. 5 and 6 the ore available was at least 561,386 tons, the existence of which had been proved by the workings up to that date. Subsequent work has shown that this amount will be exceeded. In this zone of the mine the average contents of the ore are, copper, .57%; silver, 1.74 ounce per ton, and gold, .04 ounce per ton, and its value, according to prices in March, 1901, is 15s 4d per ton. Accordingly Mr. Sticht concluded that the original ore contents of the Mount Lyell ore mass had been 4,187,499 tons, of which there was still available on March 31, 1901, 3,349,883 tons, as well as the whole of the material below No. 5 level, the amount of which could not then be calculated.

The remarkable purity of the Mount Lyell pyrites mass is one of its most striking features. It is generally uniform in grade, though the ore on the footwall side is much the richer; as a rule, the ore is completely free from any extraneous matter, but at the northern end there are some fin-like projections of schist into the pyrites.

Some masses of rich ores occur in the ore mass; most of them have already been removed by underground excavation, and they are therefore generally reported as the "stoped ores." These ores are siliceous, and the copper-bearing minerals they contain are bornite and chalcopyrite. The average analysis of these ores is as follows:

	Per Cent
Iron	24.75
Silica	30.69
Barium sulphate	1.48
Copper	5.33
Alumina	6.30
Sulphur	30.0

The bornite enrichments form shoots, extending from the surface of the ore body to below No. 7 level; they occurred at both corners of the southern end of the ore body. The material was uniform in character, and consisted of a siliceous mixture of pyrites and bornite, while in the lower depths of the mine siliceous copper pyrites was also present.

In addition to the bornite shoots there are some much smaller enrichments of fahlore. One of the most interesting was discovered in the north hanging wall drive off the main tunnel at No. 5 level. The enriched ores were there 6 feet thick on the hanging wall side of the ore mass, and contained patches of solid fahlore in pyrites. The average assay value of this material was copper 3.65%, silver 2.07 ozs. and gold .02 oz.

Similar, but apparently disconnected, shoots of the richer ore have been traced down to No. 8 level, and some of this ore was worked by a winze from the No. 7 level.

More important shoots of the richer ores have been found on the footwall side of the mine. The largest, known as the Mount Lyell Bonanza, was discovered and worked out in 1894; it yielded 850 tons of ore, which was sent to London and sold for £105,000. The bonanza was found between the pyrites mass and the lower continuation of the hematite of the Iron Blow. It consisted of a vein of copper glance (redruthite, Cu_2S) and bornite, with fahlore and argentite (silver glance, Ag_2S). It was found in a drive from the No. 4 tunnel. The entire shipment averaged 1011 ounces of silver to the ton, and one specimen which was assayed by the Tasmanian Government assayer yielded 8765 ounces of silver and 45 ounces of gold to the ton, and 19% of copper. Some specimens assayed nearly 50% silver. As the vein was followed downward it increased in thickness, being in places 2 feet in width. The discovery of this body of rich ore was of great importance in the history of the field, as it had a considerable influence in securing the capital necessary for the development of the mine.

On the footwall side, between the fifth and eighth levels, there have since been found several other fahlore enrichments; but none of them have been as important as that beneath the hematite blow.

A shoot of ore containing copper 4.55%, silver 3.58 ounces and gold .119 ounce was found in the northern drive from the No. 5 level; but this shoot was not connected with the old bonanza of the higher levels. The stopes between the sixth and seventh levels yielded ore containing copper 10.94%, silver 6.23 ounces and gold .022 ounce.

The quantity of these richer underground ores is, however, comparatively small. For the half year ending March 31, 1902, they amounted to 6479 tons, with an average assay value of copper 5.23%, silver 3.45 ounces and gold .059 ounce, and in the following half year 4595 tons, giving an assay value of copper 4.93%, silver 3.90 ounces and gold .064 ounce.

These enrichments are of considerable interest, as they throw light on the genesis of the Lyell ores. The main bonanza occurs immediately below and opposite the great body of barytic hematite of the Iron Blow.

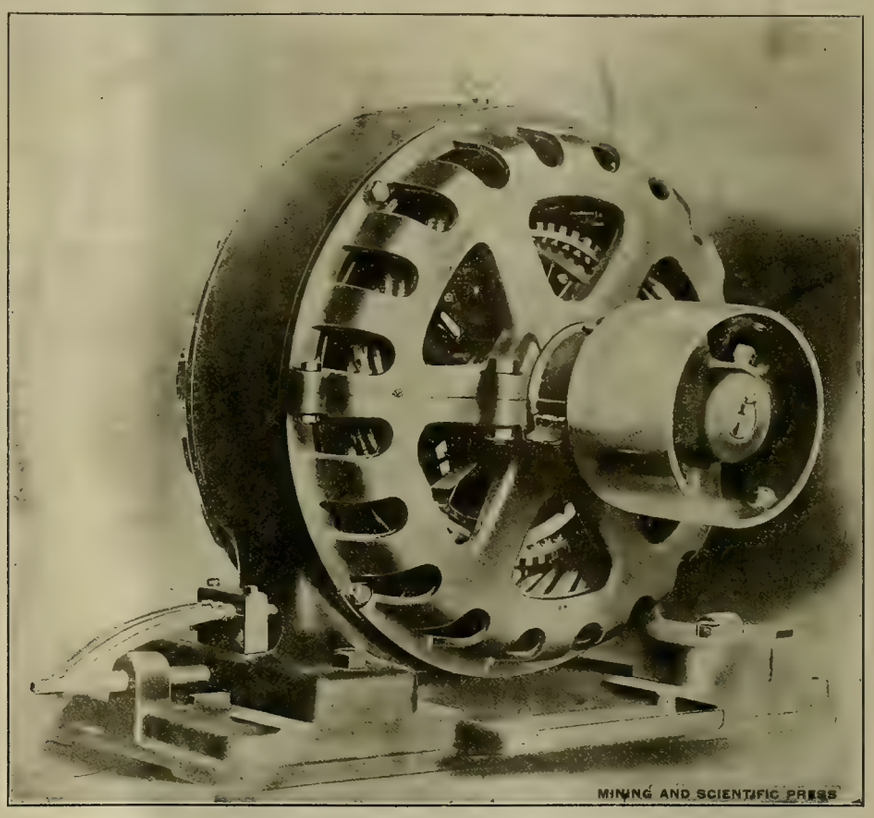
*Abstract Trans. Aus. Ins. Min. Engrs.

Polyphase Induction Motors.

A new type of polyphase induction motor has been placed on the market by the Westinghouse Electric & Manufacturing Co., which is designated as type CCL. These motors are manufactured in sizes from ½ to 75 H. P., and are wound for operation on two or three-phase circuits at voltages of 200 and 400 for all sizes except the ½ H. P. The sizes from ½ to 5 H. P., inclusive, are also wound for 100 volts. The frame of the motor consists of a solid, cylindrical cast iron yoke, to the ends of which are bolted brackets which carry the bearings. These brackets are open to provide ventilation, and may be fastened to the frame in any of four different positions, making the motor suitable for floor, wall or ceiling mounting. Motors up to and including the 5 H. P. have solid brackets and bearings, with slotted holes in the feet for adjusting the tension of the belt. Larger machines have the brackets and the bearings split horizontally, facilitating the removal of the bearings. Belt adjustment on these motors is made by tension screws which shift the motor on a cast iron bed plate. There are no wearing parts on the machine except the bearings; these are of ample dimensions, with a light rotor and flooded lubrication maintained by oil rings.



Type CCL Polyphase Induction Motor.

The stationary part of the motor is the primary, or element which is connected to the source of current. The magnetic circuit consists of circular laminations of sheet steel, securely keyed into the cast iron frame. Terminal leads are brought out at the base of the frame, held in a cast iron cleat. Hand connectors or knuckle joints, such as are supplied with railway motors, are used to connect the motor to the supply circuit.

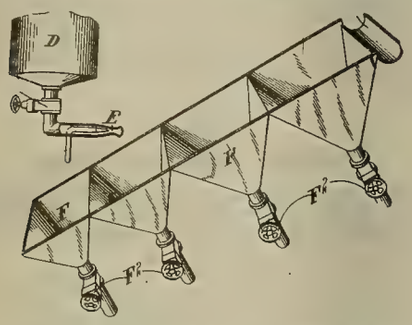
The secondaries of these motors are of the squirrel cage type. The winding consists of square copper bars lying in partially closed slots and bolted at the ends to metallic rings of ample cross-section to dissipate the heat generated in them. For the ½ H. P. motor round bars are used and are riveted to brass or copper rings at each end.

Mining and Metallurgical Patents.

PATENTS ISSUED JULY 11, 1905.

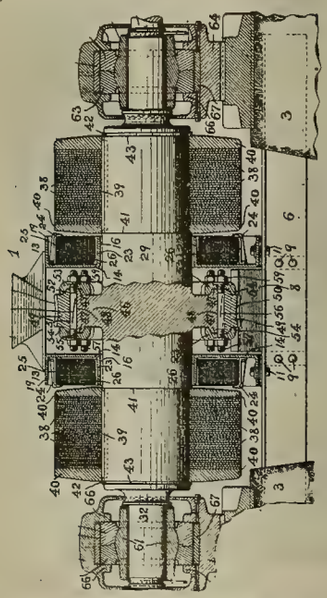
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE CONCENTRATION.—No. 793,808; H. L Sulman and H. F. Kirkpatrick-Picard, London, England.



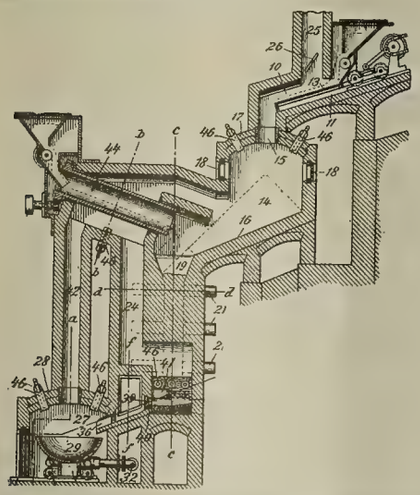
Process of concentrating ores by bringing pulp into contact with "oil" in form of spray and with gas and thereafter separating metalliferous constituents from gangue in water.

CRUSHING APPARATUS.—No. 794,703; M. Dickerson, Newark, N. J.



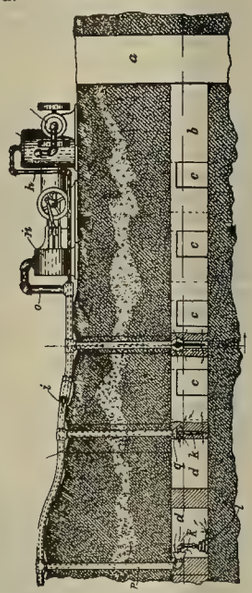
Combination, with main operating rolls arranged upon separate shafts revolving in same plane, one of rolls and shaft having pure rotary motion, and other roll and shaft being slidably mounted so as to be capable of lateral motion in plane passing through central axes of shafts, and electro-magnet encircling each shaft, electro-magnets having central axes in same plane passing through central axes of shafts, and electro-magnet on one shaft being located opposite electro-magnet upon other shaft.

METALLURGICAL FURNACE.—No. 794,212; G. H. Benjamin, New York, N. Y.



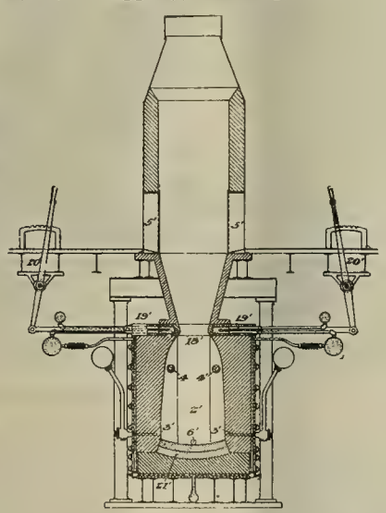
Metallurgical furnace comprising in construction calcining chamber, reducing chamber, electrically heated chamber, and oxidizing chamber arranged at progressively lower levels, together with means for creating required temperatures within chambers.

MINE VENTILATION.—No. 794,384; F. C. Weber, Pittsburg, Pa.



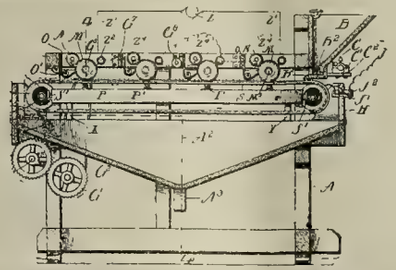
Combination with mine having shaft, main passage, and series of rooms communicating with main passage, of system of air supply pipes and exhaust pipes laid on top of ground outside mine and shaft, and having separate branches immediately tapping each of rooms independently of shaft and main passage.

METHOD OF PRODUCING COPPER MATTES, WHITE METAL AND BLISTER COPPER IN A SINGLE FURNACE.—No. 794,272; R. Baggaley, Pittsburg, Pa.



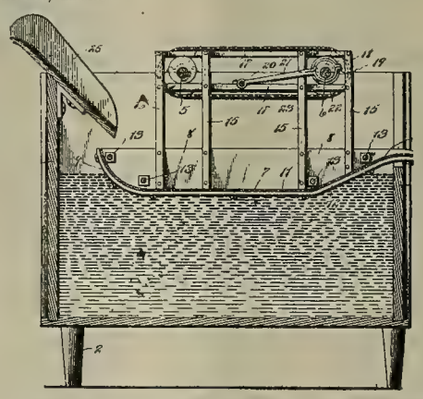
Method described of producing matte, white metal or blister copper in single vessel or chamber, which consists in producing bath by melting matte-making material in such vessel or chamber with flame applied from above, producing thereby low-grade matte, adding to molten bath from time to time ore in small quantities at a time, namely, in less quantities than molten bath, blowing air through bath, and by heat thereby developed fusing and fluxing such additions of ore.

ELECTROSTATIC MAGNETIC SEPARATOR.—No. 794,647; H. M. Sutton, W. L. Steele and E. G. Steele, Dallas, Tex.



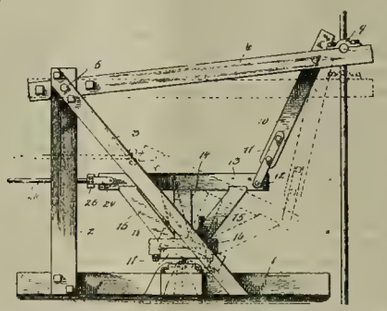
In device of class described, traveling conveyor belt, means disposed above same adapted to raise and convey material therefrom, driving shaft extending longitudinally of belt and carrying eccentrics, straps extending from belt to eccentrics, spring support for belt to permit vibration thereof, means for adjusting belt vertically relative to devices above same, longitudinal support extending between layers of belt, rollers carried by upper surface of support, speed regulating device carried by driving shaft, geared connections to speed device to drive belt, and driving connection therefrom for actuating material raising means above belt relative to speed of belt.

ORE CONCENTRATOR.—No. 794,555; H. Scovell, H. B. Scovell, L. E. Scovell and W. E. Scovell, Galena, Kans.



In device of character described, combination with fluid-holding tank, shafts mounted in suitable bearings on tank, and set of cams secured on each of shafts, one cam near each end of each shaft, of screen suspended in tank, forward end of screen having sharp upward curve, and tail portion thereof being slightly upwardly inclined to permit easy discharge of waste matter from screen, suitable hanger secured to each side of screen and supported on cams on shafts, cam secured on one of shafts, and pitman, one end pivoted to hangers and other end provided with strap adapted to embrace cam, whereby, when motion is imparted to shaft, screen will be given compound vertical and horizontal movement.

PUMPING JACK.—No. 794,546; G. Pitcher, Montpelier, Ind.

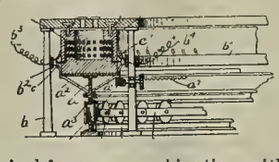


Improved pumping jack comprising sill, samson post, walking beam having one end fulcrumed upon samson post, polish rod connected to free end of walking beam, jack comprising central post, cross bar on upper end of post and extending to opposite sides of same, base block at lower end of post fulcrumed on sill, and braces between cross bar and base block, straps pivotally secured to one end of cross bar, pitman secured between straps and connecting jack with walking beam, and pull rod pivoted to opposite end of cross bar.

PROCESS OF REMOVING OR RECOVERING ZINC FROM ORES.—No. 794,198; W. Stewart, Mount Florida, Glasgow, Scotland.

Process for removing or recovering zinc from ores containing it, consisting of pulverizing ores, mixing therewith bisulphate of alkali metal, and common salt, furnacing at red heat and thereafter lixiviating or leaching and precipitating zinc salts.

ELECTRIC FURNACE.—No. 794,255; C. L. Saunders, Cleveland, Ohio.



In electrical furnace, combination with horizontal continuous annular trough forming hearth, of means for continuously rotating same, positive and negative electrodes supported on hearth and adapted to convey current to and from material thereon, stationary contact pieces with which electrodes make temporary contact, and connections from contact pieces to source of electricity.

The Use of Stulls.

The most common method of supporting mine walls is by the placing of "stulls." By stulls is meant single pieces of timber which reach from wall to wall of the deposit or vein. A stull may be only 3 or 4 feet in length, or it may be a great log over 20 feet long and from 12 to 24 inches in thickness. Ordinarily stulls vary in length greatly in the mine workings, each one being cut to fit the particular place for which it is intended. The difference in the slope angle of opposite walls of a vein, and the frequent change in the slope of the same wall—often within a short distance—makes this necessary. While the proper position of the stull, when in place in the mine, is at such an angle that it will be somewhat higher than a line normal with the average dip of the hanging wall, the ends may, and usually do, have a great variety of angle with stull itself, due to inequalities of the wall. Of course these angles usually approach 90°, but at times they depart considerably from the right angle. It is not uncommon to cut a hitch in either the foot or hanging wall, when the conditions are such that the timber cannot have a secure resting place without it. In soft rock a foot and head board must be placed in order that the ground may find sufficient support. These head and foot boards usually consist of pieces of 2 or 3 inch plank, which vary in length with the character of the ground, the soft or sloppy ground which caves readily requiring more support than where the walls are more firm. Some mines have been successfully worked by means of stulls, and the walls remained so firm over large areas that many of the stulls were knocked out and reused in other parts of the mine.

Open Cut Timbered by Stulls, Trinity County, Cal.

In some instances where timbers were not obtainable of sufficient length stulls have been spliced, but this is a dangerous practice and ought never to be attempted where the work is permanent. Instances are known where timbers 12 inches square and 20 feet in length were spliced to reach across an excavation 30 feet or more wide, but these timbers were aided by the placing of sprags at right angles to the main stulls, but the whole structure caved in in a few weeks, showing it to be insecure and unsuited to the conditions. When the stope or open cut is too wide to safely support the walls with stulls some other method of support should be adopted, the square set system being always available and satisfactory where the expense is not too great. The accompanying illustrations show two open cuts timbered by stulls—one in a mica mine, the other in a gold mine. Although these workings in both cases are superficial, the method of placing is characteristic, and is the same as that adopted in the deepest mine workings where stulls are employed. Often it is necessary to build temporary platforms to place stulls, and sometimes they are placed after a round of ore has been shot down and before it is withdrawn from the stope. In either case, and, in fact, in every case, the timbermen should see to it that the timber is securely placed and firmly wedged, and that the system of stulls is so arranged that any subsidence of the hanging wall will only serve to make the stulls the tighter, rather than to loosen them.

Production of Monazite, Zircon, Gadolinite and Tantalum in 1904.

So much has been written during the last year concerning the "tantalum lamp" and the occurrence of tantalum minerals that considerable interest is likely to attach to a report which J. H. Pratt of the United States Geological Survey has recently prepared on the production of monazite, zircon, gadolinite and columbite or tantalum minerals. These minerals are all mined for a similar purpose, that is, for use in the manufacture of electric and incandescent lamps.

Of these minerals the production of monazite is at the present time of the greatest importance, as the others have all been produced in much smaller quantities. With the exception of portions of the monazite and columbite, which were exported to Germany, all of the output of these minerals was used in the United States. The demand for monazite is constantly increasing, while there is but little increase in the use of zircon and gadolinite. The demand for columbite and other tantalum minerals has arisen only during the last year, and it is impossible to predict the extent to which these may be used.

A Vien Worked by Stulling the Walls, Crown Mica Mine, South Dakota.

The commercial value of monazite is due to the presence of thoria, which is used in the manufacture of the mantles for the Welsbach and other incandescent gaslights. The Welsbach light consists of a cylindrical hood or mantle composed of a fibrous network of the rare earths, the top of which is drawn together and held by a loop of platinum wire. The exact composition of the hoods is not generally known, as it is a trade secret, but they are composed largely of thoria with smaller quantities of the lanthanum and didymium oxides.

A portion of the cerium obtained in the reduction of the monazite is prepared for market in the form of the oxalate and is used in the drug trade.

In the chemical laboratory of the Welsbach Lighting Co. of Gloucester City, N. J., a great many chemical compounds have been made of the rare earths found in monazite, and considerable experimental work has been done to discover what economic use could be made of these compounds.

In a recent publication on the "Origin of Radium," B. B. Boltwood has shown that the proportion between the uranium and the radium in minerals is constant. One of the interesting facts brought out by Mr. Boltwood's investigations, especially as they refer to monazite, is that the thorium apparently does not participate in the production of radium and that the radio-activity of monazite is due to its uranium contents.

The sources of supply of uranium in the United States are still the deposits in North Carolina and South Carolina, and the entire production for 1904 was obtained from these States.

ZIRCON AND GADOLINITE.—The output of zircon and gadolinite is employed almost exclusively in the manufacture of chemical compounds that are utilized in the construction of the glower of the Nernst lamp. The zircon is mined for its zirconia content, and from the gadolinite is obtained yttria, these two oxides representing the principal ores used in the glower. The zircon is obtained entirely from the deposits in Henderson county, N. C., and the gadolinite is obtained from Llano county, Tex.

TANTALUM MINERALS.—The use of tantalum in the commercial world is due to the discovery that this metal is capable of withstanding the highest temperature obtained in an incandescent light, and that it is sufficiently ductile to permit its being drawn into a very fine wire, which shows little tendency to break when heated by the electric current. The experiments made in the chemical laboratory of Siemens & Halske, manufacturers of incandescent lamps, which led to the discovery of these qualities in tantalum and the invention of the tantalum lamp, are clearly recounted by Dr. Pratt.

The localities in North Carolina, Connecticut and South Dakota where tantalum minerals have been or may be found are enumerated, and a list is given of minerals that contain tantalum, together with their chemical composition and the localities where they have been discovered. The quantity of tantalum required in the manufacture of the lamps is exceedingly small, however, so that a few tons of these minerals will go a long way in supplying the demand for the metal.

PRODUCTION.—During 1904 the production of monazite, columbite, gadolinite and zircon amounted, collectively, to 745,999 pounds, valued at $85,038. Of this amount, by far the largest quantity was of monazite. There was a decrease of 119,001 pounds in 1904 in the quantity of these minerals produced, but an increase in value of $19,838. This increase in value, which accounts for the decrease in quantity, is due largely to the purer quality of the monazite which was put on the market. The larger part of the monazite was obtained from North Carolina, only small quantities coming from South Carolina. All of the zircon was obtained from North Carolina, all of the gadolinite was produced in Texas, and the columbite in South Dakota.

None of these minerals was imported into the United States during 1904, but there was a large importation of thorium nitrate, which amounted to 58,655 pounds, valued at $249,904.

About one-fourth of all the monazite mined in the United States during 1904 was exported to Germany.

Reclamation of Arid Lands in Nevada.

It was long since recognized that in most instances the arid valley lands of the great basin, and those of the Pacific coast States, which were dry and apparently sterile, only required artificial irrigation to render them productive, and that they really were wonderfully fertile lands, if this artificial irrigation could only be applied. In many instances the matter has been taken up by the citizens of certain counties and the so-called irrigation districts formed. The lands within these districts were bonded, or the necessary financial aid was provided in some other manner, and irrigation systems, some of them of considerable magnitude, were built. Dams costing hundreds of thousands of dollars were constructed, behind which artificial reservoirs were formed, the waters of winter and spring being impounded, thus creating a supply for irrigation during the long dry summer months. Some of these great dams have been doubly useful, the water being first utilized to generate power, which has been distributed electrically to mines and to other industries, and the water later used on the ranches, orchards and vineyards of the valleys.

Although some of these irrigation schemes were of considerable magnitude, there were other similar propositions of undoubted merit, but which could not be handled in the manner above referred to, for the reason that no settlers occupied the land and few would be willing to make their homes there and pledge themselves to pay for the improvements necessary to impound large amounts of water and to convey it many miles in pipes, flumes and ditches to the arid land. The proposition was too large for a district, a county or even a State. Consequently the Government has taken up a number of these larger projects in Arizona, California, Nevada, Colorado, and also east of the Rocky mountains. One of the most important of these is the reclamation of a large area in western Nevada. L. H. Taylor, engineer in charge of this great enterprise, has contributed an interesting account of the work to "The Progressive West" of Reno, Nev.—a new publication devoted to Nevada's interests—from which the following as well as the illustrations are taken:

The passage by Congress of the Act of June 17, 1902, provided Nevada's opportunity. In the early part of September, less than three months after the approval by the President of the United States of the National irrigation law, the engineers of the U. S. Geological Survey were in the field in Nevada making exploration for, and studying the feasibility of, an irrigation system, which should utilize the great volume of water flowing to waste through the rivers of the western part of the State, for reclaiming the adjacent deserts.

The first investigations of the engineers were directed to the upper portion of the Truckee river, and the valleys to the north and northeast of the city of Reno, embracing some 73,000 acres of rich land.

Exhaustive surveys were made in this district during the fall and winter, and close estimates of the cost of the requisite canals were made. It was found, however, that the cost of construction, while not prohibitive, would be relatively high, and it was deemed inadvisable to initiate work at a point where the unit cost, or cost per acre, of reclamation approached too closely the value of the reclaimed land. A preliminary investigation of the possibilities for irrigation in the vicinity of Wadsworth and in Carson Sink valley was, therefore, begun in January, 1903. Before the opening of spring, it had been determined that a large acreage—over 200,000 acres—could be watered in that region at a comparatively small expense, and it was decided to begin construction at the earliest practicable date.

The definite location of what is now known as the main Truckee canal, designed to convey Truckee river water from a point 24 miles east of Reno, a distance of 31 miles, to Carson river, was begun in April, 1903.

Bids for its construction were asked for in May of that year, opened on July 15th, and on August 28th and September 3d contracts were executed with E. B. & A. L. Stone Co. and C. A. Warren & Co., respectively, both of San Francisco, Cal., for its construction. These were the first construction contracts awarded under the Reclamation law in the United States.

This main canal has a capacity for the first 6 miles of its course for 1400 cubic feet per second—70,000

The Truckee River Near Derby, Nevada.

The Construction Camp on the Reclamation Ditch at Derby, Nevada.

miner's inches under 4-inch pressure—and, for the remainder of its course, of 1200 cubic feet per second. The depth of water will be uniformly 13 feet, and the top of banks is 2 feet above the high-water line. The width at the top varies from 24 to 63 feet, the narrow part being lined with Portland cement concrete, and having a heavy grade. Nearly 2 miles of the canal, exclusive of tunnels, are lined with concrete.

There are three tunnels of 308, 900 and 1515 feet length, respectively. All are lined with concrete, 12 feet wide, and about 16 feet high, to crown of arch inside.

The main Truckee canal will discharge its water into Carson river at the site of the lower Carson reservoir, about 9 miles west of Leetville, in Churchill county. Thence, the water flows in a channel of that stream about 4½ miles to the diversion dam at the head of the distributing system.

This dam is a concrete structure, built to last for all time, which directs the water into two main distributing canals on either side of the river. That on the south has a bed width of 22 feet, a top width of 78 feet, and carries 12 feet of water, the capacity being 1500 cubic feet per second.

The canal on the north side is 13 feet wide at bottom, 45 feet wide at top, carries 6½ feet depth of water, and has a capacity of 450 cubic feet per second.

At present, these two canals are completed for a total length of 38 miles. With their main branches, they will ultimately have a total length of over 90 miles, while the laterals and drain ditches to be constructed in Carson Sink valley alone will aggregate 1200 miles. Already, nearly 200 miles of these have been finished, and before the end of July, 1905, nearly 300 miles now under construction will be ready for use, and will distribute water to 50,000 acres of land.

This part of the irrigation system comprises the most difficult and expensive portion of the initial item of the Truckee-Carson project, and when finished, will have cost about $1,750,000. The extensions of this, in Carson Sink valley, completing the initial item, and bringing under irrigation not less than 200,000 acres of land, will increase the total expense to about $2,600,000, and consume about two years' time.

Further extensions of the Truckee-Carson project to a total area of, approximately, 375,000 acres of land, involve the construction of expensive storage reservoirs, and costly high-line canals. This work has been planned, however, and as the lands to be immediately watered are being rapidly taken by homeseekers, funds for the completion of the work will be provided by the payments to be made on the water rights therefor.

It is estimated that the entire undertaking can thus be completed within nine years, the total cost being estimated at approximately $9,000,000.

THE LANDS TO BE IRRIGATED AND DISTRIBUTED TO HOMESEEKERS.—The number of acres of land ultimately designed to be irrigated is from 300,000 to 400,000 acres, of which 200,000 will be supplied within the next three years. Of this acreage, it is estimated that about 40,000 acres will be irrigated during the present year.

The land is located in a number of valleys along the Truckee and Carson rivers, extending on each side from the Central Pacific railroad, the distance being in some places 25 miles from the road.

The main body of 200,000 acres to be irrigated first is in the Carson Sink valley, south of the railroad. Some of the land is immediately adjacent, while the farthest extends about 25 miles from the railway.

The soil is adapted to alfalfa, all forage crops, potatoes, onions, beets and other vegetables, apples, pears, berries and other hardier deciduous fruits. The soil and climate are similar to those in the vicinity of Salt Lake and Ogden.

The public lands are subject to entry under the Homestead Act, no price being charged for the land, but the cost of irrigation will be assessed against the land as a charge for the water right, to be repaid in ten annual installments without interest, at the rate of $2.60 per annum per acre. This covers the cost of maintenance and operation during the ten-year period, and provides for the delivery of water to each farm, and also for a comprehensive drainage system.

After the ten-year period stated, the land and water rights belong to the holders of the lands forever, with no further charge by the Government. The care and maintenance of the system then passes into the hands of the land owners, under laws, however, made for the purpose which will insure protection against corporate or individual greed and fraud.

The drainage is a more important factor than would be commonly supposed, as it has been estimated by the U. S. Agricultural Department that one-tenth of the land that has been irrigated by private or corporation enterprises has been greatly injured, if not permanently ruined, by too much water and too little drainage. Drainage is imperative on account of the heavy alkali deposit, which must be carried off to insure the good quality of the soil. This drainage system has increased the cost of the project from $5 to $10 an acre, but the prosperity of the settler depends upon the one about as much as upon the other.

Title to the public lands is not given until all payments for water have been made. Lands held in private ownership are supplied with water as desired, at the same price, and upon the same terms as public lands.

The public lands are now open to entry under the Homestead Act, but intending settlers are strongly advised not to file upon any of the lands outside of the district to be irrigated during the current year, and not until it is known when the water will be ready for delivery to such outside lands, for, without water, they can produce nothing which will yield them a living.

Following is specific information for the benefit of intending settlers:

The provisions of the Reclamation Law authorize the Secretary of the Interior to limit the homestead entry to any area between 40 and 160 acres, to fix the price per acre that shall be charged for water, which price shall return to the Government the cost of the irrigation works; to fix the number of annual payments, not exceeding ten, and the date when the payments shall begin; and to perform any acts and make all rules and regulations necessary to carry out the provisions of the law.

The lands under the Truckee-Carson project can be entered under the Homestead Act only. The U. S. Land Office, where entries are made, is at Carson City, Nev. There is no charge for the land other than the usual land office fees. All entries will be limited to from 40 to 160 acres of land, depending upon location, character of soil, roughness of surface and irrigability.

Site of the Lower Carson Reservoir, Near Leetville, Nevada.

All of the public land will be divided into homestead or farm tracts, each of which will embrace enough irrigable land to support a family comfortably, if well and carefully tilled under irrigation.

Any unmarried person over twenty-one years of age, or any head of a family, who is or has declared his intention to become a citizen of the United States, who has not used his or her homestead right, or who is not then owner of more than 160 acres of land in any State, can file on any one of these tracts. Title to land cannot be acquired until all payments for water have been made. The law requires a homesteader to see and select his land personally.

Residence must be established on land within six months after filing thereon, and must be continuous thereafter, and the land cultivated for the term of five years.

The cost of water to settlers has been fixed at $26 per acre irrigable, payable in ten equal annual installments, without interest.

The homestead fees and commissions for filing, payable when application is made, are as follows:

	Acres.	
For land at $2.50 per acre for	160	$22 00
For land at $2.50 per acre for	80	11 00
For land at $2.50 per acre for	40	8 00
For land at $1.25 per acre for	160	16 00
For land at $1.25 per acre for	80	8 00
For land at $1.25 per acre for	40	6 50

Originally the Homestead Law required the appli-

cant to appear personally at the District U. S. Land Office to present his application. This requirement was modified by allowing parties who are prevented by reason of distance, bodily infirmity or other good cause from personal attendance upon the U. S. Land Office to make the preliminary affidavits for homestead entries before a commissioner of the U. S. Circuit Court having jurisdiction over the county in which the land is situated, or before the judge or clerk of any court of record of such county, and to transmit the same, with their applications and the proper fees and commissions, to the register and receiver of the U. S. Land Office of the district.

The land is from 3900 to 4200 feet above sea level. The climate is dry, the mean annual precipitation being 4 to 6 inches. Snow rarely falls to a depth of 3 or 4 inches, and never lies more than a few days.

Temperatures are about the same as at Salt Lake City, and the same crops raised there flourish here.

The soils are sandy loam, and ashy in the main, but in the lower part of the Carson Sink valley they are heavier, containing an admixture of clay. It is all valley land, covered with sagebrush and greasewood.

Well water, usually of good quality, can be obtained on the lower land at from 10 to 30 feet from the surface, and on the higher land at from 100 to 160 feet depth.

The Central Pacific Railroad traverses a part of the land, but the main body of Carson Sink valley lies from 5 to 30 miles from it.

There are now 12,000 or 15,000 acres of land under cultivation in Carson Sink valley, and the present population is less than 1000.

It will take two more years to complete the construction of the system of irrigation of the above lands; water for about 40,000 acres is now available.

Ore Deposits of the Cœur d'Alene, Idaho.

NUMBER III.

Written by F. L. RANSOME.

At the beginning of 1892 most of the South Fork mines stopped work, ostensibly to secure better freight rates. Wages at this time were $3 50 a day. In the following April a reduction was made in wages, followed by a strike of the union men. The Frisco, Gem and Bunker Hill & Sullivan mines attempted to resume work with non-union men and in July were attacked by armed strikers. Troops were called into the district and for a time order was partly restored. In July, 1894, a second attack was made upon the Gem mine, and in December the Bunker Hill & Sullivan mine closed rather than accede to union demands. In June, 1895, it resumed partial operations, paying $3 a day to miners. The Tiger and Poorman mines consolidated in this year.

In May, 1898, the Empire State Mining & Development Co. was organized to control the Last Chance mine and to acquire additional territory west of Milo gulch. This was the beginning of the process of consolidation that afterwards resulted in the formation of the Federal Mining & Smelting Co The county seat was this year moved from Murray to Wallace, now the largest town in the district.

The opening of the year 1899 found the miners' unions still determined to enforce their demands upon the mine owners, and in a particularly bitter mood against the Bunker Hill & Sullivan Co., which maintained its right to employ non-union labor. On April 29 a force of several hundred men attacked the buildings of the company at Kellogg. The office of the mine was rifled and both office and mill were totally destroyed by dynamite.

After this episode 500 regular troops were sent into the district and martial law was proclaimed. The mines were closed until June, when the Standard mine reopened with men brought from Missouri. The other mines resumed work one by one as they secured non-union miners. From that time to the present no man has been able to secure employment in the larger mines (with one exception) save through the employment bureau maintained by the principal mine owners.

In 1901 the Tiger–Poorman mine, previously acquired by the Buffalo Hump Mining Co., was consolidated with the holdings of the Empire State Co., and in September, 1903, the Empire State, Standard and Mammoth properties were all consolidated under the Federal Mining & Smelting Co. Other notable events of the past few years were the discovery in 1901 of the rich ore body of the Hercules mine, which has produced ore of a gross value of about $2,000,000 in less than three years, and the development of the Snowstorm mine in 1903. This is the only mine in the district that ships copper ore.

GENERAL CHARACTER AND DISTRIBUTION OF THE ORE DEPOSITS.—The ore deposits of the Cœur d'Alene district may be divided with reference to metallic contents into three classes:

1. Lead-silver deposits.
2. Gold deposits.
3. Copper deposits.

The lead-silver deposits are in general metasomatic fissure veins, formed in greater part by replacement of siliceous sedimentary rocks along zones of fissuring. They consist essentially of galena and siderite. The gold deposits comprise bed veins, fissure veins and placers formed in at least two periods. The gold-bearing veins consist essentially of quartz carrying free gold and auriferous sulphides. The copper deposits include impregnations along certain quartzite beds and metasomatic fissure veins. The impregnated quartzite only has produced copper on a commercial scale.

These three classes of deposits are fairly distinct in their geographical distribution. The principal lead-silver deposits occur in the portion of the district drained by the South Fork of the Cœur d'Alene river and its tributaries. They fall into three main groups—one near Wardner, one near Mullan and one near Burke. The principal gold deposits are found in the country drained by the North Fork, particularly by Prichard and Beaver creeks. The copper deposits are apparently confined to the corner of the district lying southeast of a northeast-southwest line drawn through the town of Mullan.

The geological distribution of the ore deposits is of a more definite character than might have been expected from the lack of lithological contrast in the thick series of the Cœur d'Alene sediments. The gold veins, so far as known, only occur in the Prichard slate, the oldest formation in the region. These slates constitute the prevailing rock along Prichard creek from Eagle to Thompson Pass on the main divide. The principal gold quartz veins occur in this area, the most productive being between Murray and Littlefield. Another area of Prichard slate extends along the South Fork from Osburn past Kellogg and contains the gold quartz veins worked in early days on Elk creek.

The principal lead-silver deposits are in the Burke formation which overlies the Prichard and which, as already described, is prevailingly a sericitic quartzite. Probably over 75% of the lead-silver ore mined comes from this formation. The remainder is derived from the lower beds of the Revett quartzite, from the more slaty and calcareous Wallace formation, perhaps in part from the St. Regis formation, and from the upper part of the Prichard formation, which is separable merely by a rather arbitrary plane from the Burke formation, into which it really grades.

The only productive copper deposit in the district occurs in the Revett quartzite, although a number of copper prospects have been opened in the Wallace and St. Regis formations.

LEAD–SILVER DEPOSITS.—The principal companies operating in the Cœur d'Alene district on lead-silver ores are the Federal Mining & Smelting Co., owning the Tiger–Poorman mine at Burke, the Standard-Mammoth mine at Mace and the Last Chance mine at Wardner; the Bunker Hill & Sullivan Mining & Concentrating Co., owning the Bunker Hill & Sullivan mine at Wardner; Larson & Greenough, owning the Morning mine near Mullan; the Hercules Mining Co., owning the Hercules mine, and the Hecla Mining Co., owning the Hecla mine, both near Burke. Other mines which have contributed largely to the general production in the past, although they are not at present being worked on the same profitable scale as those just mentioned, are the Helena–Frisco mine near Gem, the Granite and Custer mines on the west slope of Tiger Peak, the Gold Hunter mine near Mullan, the Sierra Nevada mine about a mile west of Wardner, and the Crown Point, owned by the Cœur d'Alene Development Co., also west of Wardner but just outside of the area mapped.

Some idea of the present relative importance of the different mines may be had from the following figures derived from a table compiled by S. A. Easton, manager of the Bunker Hill & Sullivan mine, for the Mineral Industry for 1903:

GROSS VALUE OF PRODUCT FROM THE LEAD-SILVER MINES OF THE CŒUR D'ALENE DISTRICT IN 1903.

Standard-Mammoth	$2,544,918
Morning	1,635,612
Bunker Hill & Sullivan	1,604,538
Last Chance	1,409,672
Hercules	850,258
Hecla	655 72
Tiger-Poorman	580,477
Helena–Frisco	465 287
Gold Hunter	166,000
Other mines	151,735
Total	$10,064,218

The Bunker Hill & Sullivan and the Last Chance mines are both on the same general zone of fissuring and their workings connect at several points. The deepest level near Wardner is the Kellogg tunnel of the Bunker Hill & Sullivan mine. This tunnel, which is a crosscut, runs southward from the mill, situated on the South Fork, about a mile west of Kellogg, for a distance of about 12,000 feet to the lode. It cuts the latter about 2000 feet below the croppings. The Morning mine has a crosscut adit 2 miles north of Mullan, the ore being brought down to the mill on the South Fork over a narrow gauge railway. A new adit, now being run from the mill, will cut the lodes about 800 feet below the bottom of the present workings. The Gold Hunter mine is also opened by a crosscut adit, from which two lower levels are worked through a winze. The Tiger–Poorman and Hecla mines are operated through shafts in the town of Burke. These workings are respectively 1800 and 600 feet deep. The Standard–Mammoth mine has two long crosscut adits—the Campbell tunnel, running nearly north from a point on Canyon creek, just below Mace, and the No. 6 tunnel, running nearly northeast from a point on the creek, 3000 feet west and about 150 feet below the Campbell adit. From the end of the Campbell tunnel an underground shaft or winze gives access to five levels, the lowest being 1050 feet below the adit level, or about 2000 feet below the apex of the vein. The main adit of the Helena-Frisco mine is a south crosscut from Canyon creek near Gem, at the end of which is a shaft 1400 feet deep, connecting with seven levels. The main adit of the Hercules mine is on Tiger Peak, about 1½ mile north of Burke and about 1500 feet above the bed of Canyon creek. This mine as yet produces no concentrates, the crude ore being hauled by wagons to the railroads at Burke.

It appears from the foregoing that the mines working below the main canyon bottoms of the district are the Tiger–Poorman, Hecla, Standard-Mammoth and Helena–Frisco. Of these the Tiger-Poorman (1800 feet) is the deepest.

The lead-silver mines, as a rule, are equipped with excellent machinery and are operated in a first-class and substantial manner.

Most of the lead-silver deposits in the Cœur d'Alene district are metasomatic fissure veins. They are generally tabular deposits, formed partly by the filling of open spaces, but largely by replacement along zones of fissuring or of combined fissuring and shearing. The type is best exemplified by the Canyon Creek and Mullan groups of mines. The deposits worked in the mines at Wardner have different forms from those of Canyon Creek and Mullan, but, broadly regarded, fall into the same class. The ore bodies of the Granite mine also present some exceptional features, which will be adverted to later.

The general strike of the lodes is northwestward. In the Canyon Creek and Mullan groups the prevailing strike is about N. 70° W., with local variations from N. 55° W. to west. At Wardner the Bunker Hill & Sullivan–Last Chance lode strikes N. 42° to 45° W. With the exception of this lode, which dips toward the southwest at an angle of 38°, and the Sierra Nevada lode, which in places is almost horizontal, the lodes are nearly vertical. The Standard–Mammoth and Hecla dip north-northeast at an angle of about 85°. The Tiger–Poorman, Hercules and Helena-Frisco have generally south-southwest dips ranging from 75° to nearly vertical, while the Morning and Gold Hunter lodes are practically vertical.

While the fissures appear to have been opened originally by faulting, the displacement could in no case be measured, and there is usually no observable difference in the rock on each side of the fissure. The region, as has been shown, contains many large faults that have left their marks upon the geological structure. But these structurally important faults are not ore bearing.

The productive fissures are occasionally simple fractures. Usually, however, they exhibit complexity of various kinds.

In the Morning mine are two nearly parallel zones of fissuring about 1000 feet apart. The northern one, known as the Morning vein, conforms approximately to the cleavage of the sericitic Burke and Revett quartzites in which it occurs, fissuring and cleavage being so closely related that the structure may be termed a shear zone. The average width of this zone is about 9 feet The southern zone, known as the You Like vein, is similar in character but narrower, being only about 6 feet wide. In both lodes the ore occurs to some extent in small branching, irregular, or lenticular veinlets, but the ore is mainly a replacement of the country rock and as a whole has no definite walls.

In the Gold Hunter mine are three parallel lodes, which, with minor intermediate ones, constitute a shear zone about 70 feet wide, of which a small part only is productive. Structurally this zone resembles the Morning and You Like veins, but is less persistent, and the productive parts of the lode, as they are followed along their strike, lose their identity in the slaty cleavage of the Wallace and probably St. Regis formations, which form the country rock of this deposit. The Gold Hunter lode is supposed to be a continuation of the You Like vein. While this is probable, the continuity has not been established. The Gold Hunter and Morning zone of shearing and fissuring probably continues west-northwest to Canyon Creek, where it seems to be represented by the fissures of the Helena-Frisco mine, which is in the Burke formation. The lodes worked in the Helena-Frisco are three in number, known as the Black Bear, Frisco and Gem veins. They are apparently parts of a single faulted lode, as shown in Fig. 1, but as the mine was only in small part accessible at the time of visit, this hypothesis, which is strongly supported by the maps of the underground workings, could not be fully verified. The three veins, moreover, are not identical in structure or in character of ore, and it is possible that the transverse faults are older than the ore. The Black Bear vein is rarely over 3 feet wide and is a simple filled fissure with very little metasomatic replacement. The Frisco vein is also in the main a simple fissure, but a considerable part of the ore occurs as a replacement of the country rock. The Gem vein is much like the Frisco. It splits up and can not be followed after entering the intrusive mass of syenite on the west.

The Standard-Mammoth and Hecla mines are prob-

ably on a single fissure zone, but the actual continuity is broken by a northwest-southeast fault, dipping northeast, against which the vein abuts at the eastern end of the Standard-Mammoth mine. Between this fault and the Hecla shaft the vein is unknown. In the Standard-Mammoth and Hecla mines the general country rock, as in all of the large Canyon Creek mines, is the Burke formation. The ore occurs in a

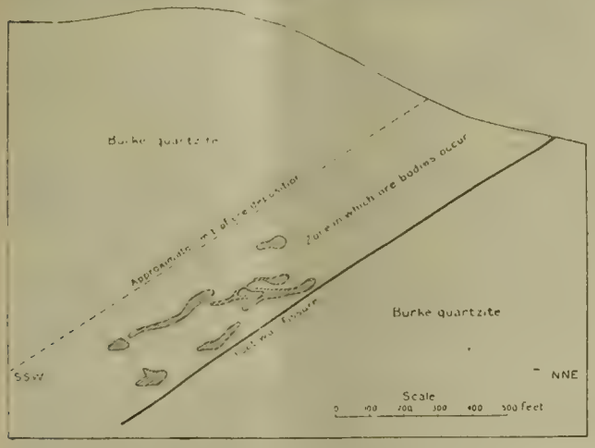


Fig. 1—Cross Section Bunker Hill & Sullivan, Showing Relation of Ore Bodies to Foot Wall.

zone of combined fissuring and shearing, partly as the filling of fissures and partly as a replacement of the sericitic quartzite. The lode has no definite walls and usually ranges from 4 to 10 feet in width. In the Hecla mine the ore usually occurs on one side of a dark narrow dike, of which no microscopical examination has yet been made, but which resembles a fine-grained diorite. Very rarely a little ore occurs as a replacement in the dike. A little of the same rock, although discontinuous and much more decomposed, occurs with the Standard-Mammoth vein.

The Tiger-Poorman lode is generally similar to the Standard-Mammoth, the ore being usually from 3 to 15 feet in width. In the eastern part of the mine the lode exhibits a well-marked linked vein or imbricated structure.

In the Wardner deposits, as exemplified in the Bunker Hill & Sullivan and Last Chance mines, there is one dominant fissure, locally known as the "foot wall," which strikes northwest and dips southwestward at an angle of 38°. The rocks on both sides of this fissure are sericitic quartzites of the Burke formation. Those in the hanging wall are much more fissured than those in the foot wall, and it is in the fissured hanging wall quartzite that the ore bodies occur. No ore of importance has yet been found in the quartzite of the foot wall in these mines. Although the main fissure was undoubtedly formed prior to the deposition of the ore, it has also been a plane of later movement, as shown by the slickensided surfaces on the ore, and it is always accompanied by soft gouge.

The zone of fissured quartzite in which the ore bodies occur has a maximum width, measured perpendicularly to the foot wall fissure, of about 300 feet. Within this zone, sometimes in contact with the foot wall, sometimes separated from it by barren quartzite, occur numerous ore bodies of very irregular shape

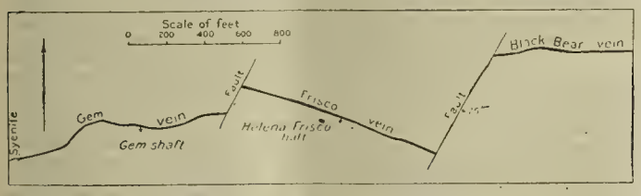

Fig. 2—Plan of the Veins in the Helena-Frisco Mine.

(see Fig. 2). The whole fissured zone, 300 feet in width, may be regarded as a single great lode, within which the partly overlapping and partly connected ore bodies are not uniformly distributed in the plane of the zone, but are grouped in at least four fairly distinct shoots, three of which have a general northwesterly pitch (in the plane of the lode) of 45°. The fourth, which is the most northwestern of the large pay shoots, occurs at the junction of the main foot wall fissure, with a zone of pressure running off into the hanging wall in a southwesterly direction and dipping southeast. This is the so-called Jersey or Skookum fissure. Along this fissure zone for a horizontal distance of nearly 500 feet, and in the pitching trough formed by the intersection with the main foot wall fissure, occurs some of the richest ore in the Wardner mines. The other pay shoots are also connected with distinct fissuring of the hanging wall quartzite, but this fissuring is elsewhere of a more irregular character than in the Jersey fissure zone. The ore of the Sierra Nevada mine also occurred in a hanging wall fissure zone connecting with the main foot wall of the Bunker Hill & Sullivan lode.

Definite walls to the ore bodies of the Wardner mines occur only where the ore rests upon the gouge seams marking the main foot wall or the foot wall of the Jersey fissure zone, or where the ore has been locally faulted. As a rule, the ore passes gradually into the unmineralized quartzite.

In the Granite mine the ore occurs in extremely irregular masses in a tongue of metamorphosed and fissured quartzite which projects into the intrusive mass of syenite north of Gem.

CHARACTER OF THE ORES.—The most characteristic minerals of the lead silver ores are galena and siderite. Both of these minerals occur as the filling of fissures and as metasomatic replacements. In many cases the galena directly replaces sericitic quartzite. But in some large ore bodies, particularly those at Wardner, the quartzite was first replaced by siderite, which was in turn replaced by galena. All stages may be seen, from siderite that is traversed by little reticulating veinlets of galena to complete replacement by the lead sulphide. That galena was formed at more than one period is shown by the fact that masses of coarsely crystalline galena are sometimes traversed by veinlets of a more compact variety of the same mineral.

Pyrite and sphalerite are found in all the deposits. The latter is particularly abundant in the Granite mine. Elsewhere it is a minor constituent of the ore and many of the deposits are remarkably free from it. The average quantity of zinc in the concentrates from the Federal Co.'s mines is about 4.5%. While most of the mines working above the main drainage lines of the district show no impoverishment of the ore through an increase of pyrite and sphalerite, the conditions in the lower levels of the Helena-Frisco, Tiger-Poorman and Standard-Mammoth indicate that such a change, probably a gradual one, may be expected at considerable depths.

Tetrahedrite occurs in bunches in the galena of the Wardner and Mullan mines and in the Standard-Mammoth. It is never very abundant and always indicates ore rich in silver. It appears to be rather more abundant near the surface than at great depth.

Chalcopyrite is very rare in the mines at Wardner. In the Standard-Mammoth mine, however, it is fairly common, though never found in large masses, and it occurs also in the Tiger Poorman, Helena-Frisco and Granite mines. It is frequently closely associated with pyrrhotite, particularly on the bottom level of the Tiger-Poorman. Pyrrhotite was detected also in the concentrates from the Morning mine. Small quantities of stibnite occur in the Gold Hunter lode.

In addition to the prevailing siderite, quartz forms a subordinate part of the gangue in all the large mines. Barite was noted in the Standard-Mammoth, Gold Hunter and Morning mines and a little calcite in the Hecla mine. As a general rule, the quartz is more abundant in the low-grade portions of the ore bodies.

The minerals found in the oxidized zone are cerussite, cerargyrite, native silver, pyromorphite and occasionally a little malachite or azurite. Limonite, of course, is always present, and results from the oxidation of the pyrite and the siderite. Plattnerite occurred in the upper tunnels of the You Like vein.

The average content of the ores in silver is a little over half an ounce to each per cent of lead per ton. During the fiscal year 1903-4 the ore of the Bunker Hill & Sullivan mine averaged 8.8% of lead and 3.9 ounces of silver. The first-class concentrates from the same mine averaged 55% lead and 19.5 ounces of silver to the ton. The ore of the Morning mine in 1903 had an average tenor of 7.4% of lead and 2.9 ounces of silver per ton. The average contents per ton in the ore of the Helena-Frisco mine in 1903 were 4.5% of lead and 2.7 ounces of silver. Such ore, however, is unprofitable. In 1897 the average of the same mine was 5.5% of lead and 4.2 ounces of silver. Probably the richest ore now produced on a large scale is that of the Hercules, with approximately 50% of lead and 45 ounces of silver to the ton. This, however, is picked material, as this mine does not at present concentrate any of its ore.

(TO BE CONTINUED.)

Trade Treatises.

"California—Her Resources and Possibilities" are described in the 15th annual report of the California State Board of Trade.

The Reynold Roller Chain, for chain drives, is tersely described in illustrated booklet No. 54 of the Link Belt Engineering Co. of Philadelphia, Pa.

Crandall Packings for steam, ammonia and hydraulic purposes are catalogued and priced in a booklet from the Crandall Packing Co. of Palmyra, N. Y.

The Allis Chalmers Co., Milwaukee, Wis., have republished Prof. H. O. Hofman's "Gold Mining in the Black Hills" in attractive form. This paper has been in demand since its first publication by the American Institute of Mining Engineers.

Personal.

F. A. HEINZE of Butte, Mont., is in London, Eng.

F. J. FROST is in Denver, Colo., from Buena Vista, Colo.

E. L. NEWHOUSE of New York City is in San Francisco, Cal.

W. R. RUST of Tacoma smelter has returned from San Francisco, Cal.

O. A. NICHOLS has taken the management Nichols M. Co. at Sherwood, Mo.

G. R. YEARSLEY has been appointed mill superintendent Pfau G. M. Co., at Cherry, Ariz.

W. L. COBB has returned to San Francisco, Cal., from mine examination at Plymouth, Cal.

J. T. WELLS has resigned as superintendent Luna Lead Co.'s smelter at Deming, N. M.

JAS. HAMPTON has been appointed foreman Oneida mine at Jackson, Amador county, Cal.

THOS. H. LEGGETT, mining engineer of San Francisco, Cal., has returned from London, England.

L. M. ADSIT has been appointed assistant superintendent Highland Boy mine at Bingham, Utah.

A. W. ROBBINS has been appointed superintendent Gold Sovereign mine at Cripple Creek, Colo.

A. B. ROYAL has returned to Pasadena, Cal., after examining mines at Cerbat, Mohave county, Ariz.

S. E. BRETHERTON of Joplin, Mo., has charge of the Afterthought smelter at Ingot, Shasta county, Cal.

G. D. REID has resigned as superintendent Ladds Metal Co. of Portland, Or., and will examine mines in Mexico.

C. R. NORRIS, superintendent Great Sulphide mine near Tucson, Ariz., is consulting with stockholders at Oxnard, Cal.

E. P. POPE, treasurer La Libertad M. Co. of Altar, Sonora, Mexico, has returned to Parkersburg, W. Va., from the mine.

W. F. DE CAMP, formerly superintendent, has been appointed manager El Tigre mine, with headquarters at Douglas, Ariz.

G. H. HOOPER AND E. G. ECKIS of Los Angeles, Cal., have been examining the Midnight and Pinkham mines at Chloride, Ariz.

R. L. HENDRICK has been appointed superintendent Black Hawk mine at Soulsbyville, Cal., succeeding R. H. Barnes, resigned.

J. A. CREIGHTON has been appointed superintendent Dalton & Lark mines at Bingham, Utah, succeeding Chas Lawton, resigned.

WM. CLARK of Grass Valley, Cal., has been appointed superintendent Eagle & Blue Bell mines at Eureka, Utah, succeeding J. A. Creighton.

G. W. MYERS, representative Chrome Steel Works, has left San Francisco, Cal., on the Sierra for Australia, whence he will visit Japan and China.

W. C. BOGUE, Salt Lake City, Utah, has resigned as local manager Mine & Smelter Supply Co. and will be manager Western Iron Mills Co. at Denver, Colo.

T. H. OXNAM, formerly manager, has been retained as consulting engineer for the Palmarejo & Mexican Goldfields, Ltd., at Chinipas, Chihuahua, Mexico.

W. D. WALTMAN, formerly of Cripple Creek, Colo., is supervisor of mining for the Mining Bureau of the Panama Canal Commission at Empire, Canal Zone, Panama.

R. H. BARNES has resigned as superintendent Black Hawk mine at Soulsbyville, Cal., and will go to Sinaloa, Mexico, on professional business for the Black Hawk M. Co.

W. B. ROUNTREE, chief assayer and chemist for the Mountain Copper Co. at Keswick, Cal., has been transferred to the company's new reduction plant at Martinez, Cal.

WM. A. POMEROY, recent manager Great Fingall mine, West Australia, has been appointed manager Palmarejo & Mexican Goldfields, Ltd., at Chinipas, Chihuahua, Mexico.

DANIEL GUGGENHEIM, ROBT. GUGGENHEIM, S. W. ECCLES AND H. B. TOOKER, all of American Securities Co., are in San Francisco, Cal., to plan improvements for the Selby and Tacoma smelters.

A. H. WHITESIDE of the Allis-Chalmers Co.'s office at Atlanta, Ga., is transferred to the Philadelphia district office, where he succeeds as manager W. A. Wood, resigned. M. W. Thomas has been appointed Atlanta manager. W. J. Buckley has been appointed St. Louis manager. H. P. Hill, whom he succeeds, goes to the Salt Lake City office.

Obituary.

W. F. NEWELL, ore buyer for the Selby Smelting Works, died July 19 in Oakland, Cal., age 47 years. He was one of the best known mineralogists on the Pacific coast.

W. F. PATRICK, for years one of the leading mine operators of Colorado, died July 14 at Rhyolite, Nev. He, with his brother, L. L. Patrick, was one of the leading owners of the Combination mine at Rhyolite.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

The 14 miles of railroad from Chena to Fairbanks was completed July 18. A branch road to the creeks is graded and expected to be in operation by September.

An important decision affecting the mining interests of Alaska has been rendered by Judge Wickersham at Fairbanks. Miners there believe it will do more toward the development of the resources of that country than anything else which has occurred within recent years. The judgment will result in developing the country by compelling men who lay claim to mineral ground to dig into it in order to make good their rights. The posting of a notice of location is no longer sufficient. Judge Wickersham defines the rights of the miner and locator in unmistakable terms, as follows: "Discovery of mineral is necessary to the validity of a placer mining claim. If staking and recording shall follow after the date of the discovery they relate back to the discovery, and, in case no intervening rights have attached, perfect the claim as of that date. But it is not so with the discovery. If acts of staking and recording are performed first, as in this case, and discovery last, the validity and life of the claim begin only with the discovery. The greatest evil in the administration of mining law in Alaska is the habit of the shiftless, in staking and recording claims, generally by power of attorney, whereby one person out of ten acquires a claim to a large area of supposed mineral lands and excludes the willing miner from working it and developing the resources of the Territory. Since the threat of lawsuit lurks behind each of these pretended locations, the prospector generally passes it by, and thus the speculative locator controls the property.

ARIZONA.

Cochise County.

(Special Correspondence).—R. Mitchell of Los Angeles, Cal., and associates have completed details for a smelter at Naco. The capacity of the plant is 250 tons a day, and the works will be devoted almost entirely to copper ores.

Naco, July 16.

(Special Correspondence).—T. King and J. Warren of Johnson are mining and shipping ore from that camp to El Paso. There is considerable mining going on in the district. The Arizona Con. is shipping a good grade of sulphide copper from the Republic and Mammoth mines.

Johnson, July 15.

P. S. Simmons, president of the Flourine M. Co., at Pearce, reports that the shaft is down 75 feet and a vein of silver has been cut.——It is reported that the Tombstone Consolidated Mines Co. is to begin the treatment of a portion of its ores by the cyanide process.

On the 700-foot level on the Shattuck & Arizona a fine body of ore has been found. The main shaft is down 750 feet. The pumps are in operation. Superintendent Pattison will resume work in the bottom of the shaft as soon as the water is taken out.——Of the Copper Glance property, near Bisbee, the stockholders are left with the patented ground, as the machinery has been taken off.

Gila County.

The Arizona Commercial Copper Co. have completed track connecting the Copper Hill mine with the United Globe surface tramway and are shipping ore to the Old Dominion smelter. Initial shipments will not exceed 100 tons per day, but will be gradually increased.

Graham County.

(Special Correspondence).—The output of copper in the Clifton-Morenci district for June was nearly 3000 tons with the increased facilities for reduction now being installed; an increase of 500 tons per month is expected by Jan. 1, 1906. The Arizona Copper Co. is driving a tunnel through the mountain at Morenci to connect the Humboldt mine with the new concentrator they are building. This company is also sinking their main working shaft on the Big Coronado lead an additional 200 feet from the 500 to the 700-foot level.——The Coronado Copper M. Co. is putting in a gasoline hoist at the Garnet shaft.——The Crawford Gold M. Co. has opened up a high grade gold ore.——The Shannon Copper Co. is shipping on an average 900 tons of ore daily. This company is putting in converters at their smelter and hereafter will treat their own matte instead of getting it done by the Arizona Copper Co.

Metcalf, July 16.

Announcement is made that the Shannon Co., at Clifton, will have a converter plant in operation before the close of the year. Heretofore the Shannon matte has been run through the converters of the Arizona Copper Co. in Clifton, at much expense through transportation and cooling.——A briqueting plant is being added to the equipment of the Arizona Copper Co. of Clifton, with capacity for compressing twenty-five tons a day of slack coal, coke or flue dust.

Two shifts are at work on the Weaver mines in Greenlee district, north of Clifton.

Mohave County.

W. C. Howard, general manager of the Katherine and other mines in the Pyramid section, 20 miles from Kingman, is putting in a large pumping plant for the mill and a new hoisting plant. The main shaft is down 200 feet on the Katherine mine.

Pima County.

C. R. Norris, superintendent of the Great Sulphide mines near Tucson, reports that the main shaft is down 200 feet. The new railway from Tucson to the Copper Belt mines passes within 6 miles of the Great Sulphide workings. Work has been temporarily suspended.

Pinal County.

The leaching experiment on the Ray mine, near Kelvin, is apparently giving satisfaction. Electricity is used as a precipitating agent. The company thinks that it will be ready to commence active operations in both mine and smelter within a month.——A stamp mill is to be put in at the Lucien Walker mine in the Casa Grande district.

Yavapai County.

Work has begun on the excavations for the smelting plant and necessary buildings at the Val Verde mine.——The main shaft of the Pine Mountain mine, at Walker, is to be sunk 400 feet deeper from the present 200-foot level, where crosscutting will be done to follow up the ore bodies.——The Gold-Copper Co. is working mines south of Prescott under the direction of T. Marmont.——Work is to begin on the Rosalie copper mines near Mayer with ten men. D. J. Thompson of Prescott is one of the owners.

The Sayer G. M. Co. intends to sink their main shaft east of Martinez 100 feet deeper and will then drift on the vein to show the extent of the ore body.——It is reported that work is to be resumed at the Octave mine at Octave upon the return of Superintendent A. E. Hurley from the East.——A hoist and pump are to be put on the Octave Extension gold mines, which are being worked by the Southwestern Development Co.——C. E. Butler and associates will place a hoist and pump on the Commodore mine preparatory to sinking the shaft.——The Alaska group, near Congress, with D. J. Sullivan as manager, will soon put up a hoist.——The Planet Saturn group, east of Martinez, has recently been bonded to a company who will unwater the main shaft and commence active development work. The main shaft is down over 1000 feet.——East of Martinez the Rincon Mines Co. are building a new mill.——Recently fire destroyed the blacksmith shop and pump house at the Pfau mine in the Cherry Creek district, but has not interfered with the working of the mine, and everything is to be replaced.

Yuma County.

(Special Correspondence).—The California & Arizona M. Co. are employing a good force on their claims at Melton. The work consists principally of tunnels run off on the veins and in making upraises for the purpose of obtaining better ventilation. Two shipments of ore have been made.

Melton, July 15.

CALIFORNIA.

Butte County.

Articles of incorporation of the Cascade Placer Corporation have been filed at Oroville. The purpose is to develop the Cascade mine, 12 miles above Lumpkin.

It is reported that the deal pending between the London Venture Corporation and the owners of several dredger properties on the Feather river for the sale of the latter has finally been effected in London. The properties involved are the Boston & California and the Boston & Oroville companies, the Oroville Gold Dredging & Exploration Co. and the Bear River Co. The latter is on the Bear river. The price agreed upon is said to be $3,000,000. Among the owners of these properties are Evans & Clark of Boston and W. P. Hammon and A. F. Jones of Oroville, the estate of the late J. E. Doolittle, F. W. Bradley, W. H. Crocker, the Guggenheims, J. H. Hammond and several others. There are eight dredgers already at work on these properties and orders for six more have been placed.

Calaveras County.

Work has been commenced on the San Andreas quartz mine at San Andreas, under the direction of John Henry.——The air connection has been finished at Reed's mine on Central hill, near San Andreas.——The Bertola and Zugar gravel mines, between El Dorado and Sheepranch, have been bonded through E. C. Rigney of El Dorado to Los Angeles capitalists, and development work on the properties, with Mr. Rigney as general manager, will commence on July 15.——The owners of the Gum Boot mine, near Esmeralda, have bonded their property to a company, with John Campbell of Murphys as general manager.——The new mill for the Clary G. M. Co. is being built on the South Bank mine at Indian creek, near Sheepranch.——Work at the Ohio mine on Indian creek, near Esmeralda, is under the superintendency of W. L. Driver of Murphys. At present there is a force of eight men at work, and this will be increased as the work advances sufficiently to advantageously work a larger number of men.

Contra Costa County.

The smelter trust, of which D. Guggenheim of New York, now in San Francisco, is the head, is considering plans for establishing a smelting plant at a point, yet to be selected, on the bay shore between San Francisco and Port Costa. It is proposed to have the works convenient to the Southern Pacific and Santa Fe railroads. It has been realized that the Selby smelter is inadequate for the business which the trust intends to develop on this coast. It was announced recently by D. Guggenheim that his company would enlarge the works at Port Costa, but since then the officials of the trust have been made to realize that the site of the works is not of sufficient size to permit the improvements contemplated. In consequence it has been decided to erect another and larger works, similar to those at Tacoma, at a point farther south, where connections can be made with both the Southern Pacific and the Santa Fe lines. It is very likely that before purchasing a site the trust officials will secure title to many pieces of land adjacent to the bay shore in order to obviate the possibility of farmers protesting against the establishment of the new works.

El Dorado County.

Half of Grizzly Flat was destroyed by fire July 18.

Kern County.

For the first time since 1897, when, by an act of the Legislature, mining districts were abolished, Kern county is to have an organized mining district, that of Amalie. This district was first organized in 1895, and did not take advantage of the new laws when the Legislature of 1899 repealed the act of 1897. Since that time all locations of Amalie, as of other districts in the county, have been filed with the county recorder.

Mariposa County.

G. Dwart, treasurer of the Alice G. M. Co., and C. Ollinger, president and general manager, purchased the Alice mine from Carroll & McCrossen last December. The mine is in Hunter's valley near Merced river, near Mariposa. The old shaft is being repaired and enlarged. It is 85 feet deep and will be sunk 90 feet farther, when drifts will be run. After the mine has been developed it is the intention to build a mill. —— The California-Tennessee G. M. Co. are building a hoist and 10-stamp mill at Indian gulch. The hoist will be run by gasoline, the mill by steam. The mill is expected to begin crushing on July 26th. The shaft at the mine is down 200 feet.

Nevada County.

New concentrators and a canvas plant are to be put in at the 16 to 1 mine near Washington. F. M. Egan of Sacramento, president of the company, is at the mine. There is talk of putting in a chlorination plant at the mine, also to put in a new hoist, preparatory to sinking. J. H. English is superintendent.

The Majestic mine, in Rough and Ready district, has been started under the management of W. G. Dround. The shaft is being unwatered preparatory to sinking from the 250-foot level.——At Cherokee Flat, the Morning Star is grading for its projected mill. Its new shaft is down 100 feet, and, in addition, the owners intend to sink the old shaft several hundred feet deeper.

It is reported that tributers, headed by H. J. Stewart, have started work at the Union Hill mine, near Grass Valley. The pumps are unwatering the mine. The company will furnish material and keep the pumps running, working on a percentage basis with the men. The crew expects to go down the creek 1200 feet and sink a new shaft.——The Neversweat mine, at Willow Valley, is to be developed by C. Fischer and J. F. Dietrich of Gold Hill, Nev. They are extending two of the three tunnels on the mine. The lower, or drain tunnel, will be driven in along the ledge.——The hoist on the old Spanish mine, in Woods ravine, has been sold to the Esperance M. Co. of French Corral, who will move it to their mine.

Never before in history has Cherokee and Badger Hill had brighter prospects ahead than at present. The Morning Star mine has some forty men at work in the mine, grading for the mill and doing other work, and the Badger Hill Gravel Co. is figuring on sinking a shaft to tap the gravel channel. It is believed that the property will pay to work by the drifting process. Many years ago the Badger Hill was operated through the hydraulicking process and it paid handsome dividends. There is still a great bank of gravel left, and the owners, the Bloomfield Co., are now preparing to start a shaft and run drifts. The shaft at the Morning Star is now down about 100 feet and the ledge still holds good. It is their intention soon to open the old shaft, to the west from the new one, which is about 170 feet deep. There is a hoisting and pumping rig on the old shaft.

Placer County.

The Tadpole mine, 5 miles above Westville, is reported to be working four men, and ore will be crushed at the Alameda mill, at Black canyon, until the mine is thoroughly tested and prospected.——L. C. Trent, president of the Dairy Farm mine, 7 miles north of Lincoln, intends to build a railroad from the Dairy Farm mine to the main line of the Southern Pacific Co.——The Blue Jay mine, in the Dairy Farm district, owned by Price, is said to be showing up well.——The machinery at the Bellevue mine, near Ophir, has been started by Buchanan & Lozano.

Shasta County.

It is reported that the Afterthought smelter at Ingot is in successful operation under the direction of S. E. Bretherton.

A company organized with T. Shonts, head of the Panama Canal Commission, as a stockholder and director, has purchased the Boulder mine, near Castella.

The Delta Con. has bought the Delta and the Bacchus mines, 6 miles from Delta. The Delta mine was purchased from F. M. Johnson of San Francisco and the Bacchus from E. F. Fitzpatrick of Redwood City. The acquisition of these mines by the Delta Con. will mean the reopening of the Dog Creek gold regions and a railroad and smelter may be built within a year.

Sierra County.

The Downieville Messenger reports that work is steadily progressing at the White Bear mine, near Downieville, with twenty-five men, under the superintendency of W. J. Belcher. Power drills have recently been put in to facilitate the running of the hard rock tunnel to open up the channel to the north.—For the last twelve months the crew at the Exchange mine, near Monte Cristo, owned by J. Peckwith, T. Peckwith and H. Spaulding, Jr., have been enlarging the tunnel and constructing an airway alongside the tunnel, and reopening an old air shaft. This work is now about completed and they are ready to begin the extraction of gravel, of which they have a large body already developed. The channel is said to be the continuation of the White Bear channel.——At the Papoose mine in Jim Crow canyon, near Downieville, W. H. Corbiere, who has a bond on the property, has struck the ledge in a new tunnel, below the upper workings.——At Happy Hollow, near Port Wine, twenty-five men are employed, under the management of A. F. Eaton of San Jose, who has been reappointed manager of the Tabor mine at Gibsonville.——Rich sulphurets have been struck at the Last Resort mine at Downieville. F. E. Wilber, vice-president, is expected from Guthrie, Okla., August 1 to make an examination of the property.

At the annual meeting of the Poker Flat G. M. & M. Co. of Poker Flat, near Table Rock, the following officers and directors were elected: President, O. P. Cooper, Guthrie, Okla.; vice-president, C. H. Molter, Berkeley; secretary, F. P. Roddy; treasurer and manager, E. L. Blincoe; directors, J. Duke, Guthrie, Okla.; J. B. Lassiat, Downieville; C. Berg, San Francisco. The company is reducing their capital stock from 1,000,000 shares to 100,000. The further work of the mine will be conducted by Mr. Blincoe.

Work is to be started at the Herkimer gravel mine, near Poker Flat, Table Rock P. O., owned by H. L. Huntington and W. P. Sawyer, both of Nevada City. H. Fowler is to run a tunnel to tap the channel 800 feet in.

Siskiyou County.

The mill at the Mabel mine on Mill creek, near Scott

Bar, 15 miles from Montague, is crushing good ore. W. H. Parker has a cyanide plant at the mill with which he is working the tailings pile.——At Humbug creek the Mono Co. is building a 25-ton mill and cyanide plant.——Superintendent Tibbetts of the Headwaters mine, near Humbug, is running a 400-foot crosscut tunnel to strike the ledge at lower depth.

Sutter County.

It is reported that a prospecting drill is to be placed on T. L. Smith's land near Yuba City as a result of preliminary tests on the gold-bearing gravels.

Trinity County.

W. Stover, who has bonded the Beaudry mine, at Minersville, near Weaver, intends to work the low ground with a hydraulic elevator.——Lorenz Bros. have bought the Wallace mine, on Steiner's Flat, 3 miles from Douglas City, from J. C. and L. J. Wallace.

Tuolumne County.

(Special Correspondence).—The double-compartment shaft of the Black Hawk mine, at Soulsbyville, is down 100 feet and a crosscut is being driven to cut the ledge. Superintendent R. H. Hendricks has eight men at work.

Soulsbyville, July 19.

Work is to be resumed at the Del Monte mine, near Groveland.——A new steel hoist is being put up at the Arrow mine, west of Soulsbyville.——The stamps added to the mill at the Longfellow have commenced pounding on good ore. The shaft has been enlarged and retimbered and drifting is being done on the 300, 450 and 600 levels.

J. M. Merrill will start work at the Cosmopolite mine, near Groveland. A small stamp mill will be put in at once. W. Waldron is superintendent.

COLORADO.

(Special Correspondence).—The American Mining Congress, with headquarters in Denver, will hold a meeting to decide on future work for the association. One of the questions to come before the meeting will be the raising of sufficient money to build suitable headquarters for the congress. It is understood the method for raising the necessary capital will be by subscription and sale of stock in the association. It is stated, by parties who are in a position to know, that several leading mining men of the State and country at large have come forward with good subscriptions and that the building will be an assured fact. The congress expects to expend $500,000 on the building. It is also the intention of the association to secure a large display of minerals from different sections.

The report comes from the Cripple Creek district that a number of assayers in the district have been placed under arrest for receiving stolen ore from the "high graders." With some assayers this seems to be the height of their ambition to act as a fence for the ore thieves. Were it not for the fact that some of the assayers make it a part of their "professional duty" to handle that class of work, the operators would not find it so difficult to weed out the high graders in the mines. It is said that assayers who follow the vocation of buying high-grade ores that have been stolen make a small fortune out of the work each year.

The State will have a bill of about $2500 to settle with the citizens of Telluride on account of "lost arms" which the militia took from the citizens during the recent strike in that vicinity and which have not been returned to the owners.

The anti-boycott measure passed at the last meeting of the Legislature is to take effect some time during this month and is intended to stop boycotting, picketing and blacklisting. The law is intended to work in favor of both employer and employe. Under the new law the employer will not be permitted to blacklist employes and employes will not be permitted to boycott the employer.

It is understood the Government will not take action against the Moffat road for right-of-way through Gore canyon and that the suit recently started against the road will be dropped. From indications the Moffat road will not be enjoined from building their line through the canyon.

It is the opinion of a prominent mining engineer that should the merger of the railroads take place in the Cripple Creek district and the transportation charges raised it will be a good thing for Cripple Creek and vicinity, as the operators will then begin to develop different processes for handling the low-grade material and thereby avoid heavy shipping charges.

Denver, July 17.

Clear Creek County.

At Idaho Springs the Columbia mine, on Chicago mountain, the western extension of which forms the junction with the Great Republican vein, has resumed after lying idle for nearly five years. It is being worked by a pool of Idaho Springs men, including J. G. Roberts, W. G. Arkills (manager of the Star tunnel), E. R. Lumley, M. C. Potter, R. R. Graham, J. Nelson and J. W. Anderson.

It is reported that W. Rogers, general manager of the Santiago mine, in the Argentine district, has bought the old Clear Creek mill, in the south end of Georgetown. The entire plant will be overhauled and new and modern machinery will be put in.

Manager Wilcox of the Waldorf Co., operating in Argentine district, near Georgetown, has made a good strike at the junction of the Paymaster and Commonwealth veins through a 75-foot lateral drift from the main tunnel. The junction is 690 feet below the lowest of the upper workings, which will enable the manager to drive seven levels, 100 feet apart, and open rich ground. The Wilcox tunnel will be continued on its projected line to cut the Mendham, Wheeling Johnson, Independence and other veins at a depth of 1700 feet below the old shaft workings. The first of the veins will be cut 1000 feet beyond the present heading, and the others a short distance ahead of the Mendham. The building is finished and the machinery on the ground ready for installation and will be ready to run within two months. It will be a duplicate of the Stevens mill. From the dumps and stopes of the Stevens mine they are taking formerly rejected stuff, milling at a cost of 93 cents a ton average and getting out of it $8000 to $10,000 a month. They are putting in twelve machine drills into the Tobin mine and in the ore bodies of the big tunnel. Much of this is high grade which will be sent to the smelters direct, the lower being reserved for milling.

The Ramsdale claims on Lincoln mountain have been sold to G. W. Teagarden and A. B. Montgomery of Georgetown, representing Eastern capitalists, for $35,000. This property was owned by H. G. Haeseler and H. J. Crist of Georgetown and W. Schauer of Longmont. The Ramsdale group is in the new gold belt of upper Clear Creek. The crosscut has been driven 450 feet, with 150 feet of drifting on the Ramsdale lode. In addition to this a number of shafts have been sunk on the various lodes belonging to the group. It is the purpose of the new purchasers to put in heavy machinery within the next month and a concentrator is also discussed. Other property owners of Lincoln mountain are making arrangements for the resumption of work.

The new conveyor has arrived at the Mendota mill at Silver Plume and operations at the mill have been resumed on material from the dump, as it is desired to treat as much of the dump stuff as possible during the summer months. In the winter bad weather will not interfere with getting the ore out of the mine for concentration, and some work is being carried on in the mine for the purpose of getting the old workings in shape for running the stopes and taking down the streaks of low-grade ore that were left when the lead streaks were worked out, as there was no money in zinc ore then, while it now proves to be very profitable where the ore can be concentrated.

The Silver Standard says that what seems to be needed for the development of the mineral resources of McClellan mountain is the driving of a tunnel from the Silver Plume side of it similar to the enterprises that are being carried on in the East Argentine district for the development and economical working of the veins there. The most advantageous location for such a tunnel would seem to be in the territory embraced in the holdings of the Silver Plume Mines & Tunnel Co., the group of claims owned by Aldrich, the Daisy group and J. W. Boughton's claims.

El Paso County.

F. F. Castello has been elected president of the Colorado Springs Mining Stock Exchange; J. A. Hayes, first vice-president; J. R. McKinnie, second vice-president; J. A. Connell, third vice-president, and W. P. Kinney, secretary and treasurer.

Fremont County.

Engineers have finished the preliminary survey of the Great Western railway, connecting the Great Western coal mines with Canon City, a distance of 5 miles. This is believed to be the preliminary step toward building south to Trinidad and from that point south to El Paso, Tex.

Gilpin County.

It is reported that work will be started at Golden Rod M. & M. Co.'s mines, up Silver creek, near Central City, August 1, by which time the water will have subsided.——At the Mascot shaft of the Boston-Occidental M. Co. at American City the shaft has passed the 300-foot point and good headway is being made in deepening it. The shaft is being sunk vertical, is 8x10 feet in the clear and is of two compartments, and will cut the vein at a depth of 370 feet, as the vein is dipping north. The 280-foot crosscut is in 30 feet and is being extended to the vein. At the 200-foot level the vein is 16 feet wide. The work is in charge of Foreman S. Reid.——F. Ingram and L. J. Mountz, owners of the Jim tunnel property on Elk creek, near Central City, have run the tunnel in 200 feet.——The foundation work on the drying room for the Boston-Occidental M. Co., on Colorado hill, has been completed and the contract for the new building has been given to G. Converse, who has commenced work.——Manager L. J. Mountz of the Cyrene Gold Mines Co., operating in the Twelve Mile section, is asking for bids for sinking the main shaft down another lift of 100 feet and for drifting 100 feet. The main shaft is down 130 feet and in the lower levels a good body of ore of a concentrating and smelting character has been disclosed.

The United Mining & Exploration Co., operating the Modoc mine, on Quartz hill, has put in a boiler and small air compressor. Free-milling ore has been opened in the 200-foot workings, and it is the intention of the company to upraise from the workings, to make a cage shaft to handle the increasing production.——The Pioneer tunnel of the Decatur Gold M., M. & T. Co., in Moon gulch, under the management of W. M. Ashmore, is in 630 feet.

Gunnison County.

E. V. Neelands, superintendent of the Black Queen mine, is pushing the work at the new Belle mill at Crystal.——A. Burnett and G. Tays are getting ready for work at the Copper King mine, near Marble.——In the Tin Cup mining district the Gold Cup mine, operated by I. L. Johnson, has started the new drainage and transportation tunnel projected to run a mile, under the 500 acres controlled by the Gold Cup Co. and other properties.——On the Blistered Horn tunnel, near Tin Cup, operated by Andrew Lejune to develop depths of the Jimmy Mack mine, the tunnel is in 1400 feet.——L. Cavnah, as manager of the West Gold Hill property of Tin Cup, has been operating a cyanide mill of 100-ton capacity, treating fifty tons a day during the spring, and apparently making it a success. Recently an accident to the 2400-foot tramway has shut down the mill for a time, but it will probably start again this month.

The Cumberland mine, one of the Raymond group of Pitkin, is shipping.——W. Scott is unwatering the Williams shaft, near Pitkin, preparatory to opening the lower levels.——G. Kellogg of the Chloride mine, near Pitkin, is having the mine unwatered. Negotiations are pending for the lease of the Mono mill, which will be used to treat the ore from the Chloride by cyanide.——The Gold Cross M. & M. Co. has bought seventy-seven acres of the patented timber tract of S. Dickinson, which lies near their workings west of Bowerman.

Lake County.

In Sayers' gulch, near Twin Lakes, J. A. Storm is developing the Bedford group of ten claims.——A. Kindel and associates are operating the First Discovery and have a very promising prospect.——M. Sargent expects to resume development on the Ida May group.——Preparations will be made to commence sinking a new shaft on the Diamond Joe group, of which W. E. N. Wright is the superintendent. This property is on the eastern slope of Mount Ewing.

The Parson shaft, lower Rock hill, Leadville, is down 200 feet and is entering the lake bedding. Trouble is being experienced with water, the shaft making 200 gallons per minute. The trouble is not so much from the flow of water as from the sand that gets into the valves of the pumps, making sinking slow.

Trouble has been had at No. 1 shaft of the Resurrection mine, of Leadville, on account of an extra flow of water, but the pumps at No. 3 shaft were started and the water has been lowered sufficiently to permit of work being carried on.——The Silent Friend shaft is down 400 feet and another lift is being sunk to catch the ore shoot, which is dipping rapidly.——Prospect work has been resumed on the Gold Basin, near Leadville.

Mineral County.

The Creede United Mines Co. has bought the Big Kanawha Leasing Co. and the Humphreys T. & M. Co., including the mill, all three concerns being consolidated under the Creede United Mines Co. According to G. Davis, the manager, they expect to mine and mill 6000 tons of ore monthly and will make improvements in the mill. About 175 men are employed in the mine and mill. The mill is turning out 600 to 800 tons of concentrates monthly and is making fine recoveries of zinc and other associated values.

San Juan County.

D. E. Carmichael and J. H. Kramer have started work at the Silver Ledge mine and mill near Silverton.——The tunnel being run to cut the Bullion King vein, near Silverton, has been driven 600 feet by Manager A. J. Aurand.

Work is progressing on the new branch railroad from Howardsville to the Green Mountain M. Co. property. The railroad will be 2 miles long, its construction costing $50,000 per mile.

San Miguel County.

R. J. McCarthy has started work near Ophir.——G. Southard, M. K. Monroe and J. C. Ferguson have taken a lease on the Osceola mine, near Ophir.

Summit County.

Kaiser & Madron, operating the Germania on Little mountain, near Breckenridge, have a carload of silver-lead ore to ship.——At the Abundance G. M. & M. Co. on Mineral hill, near Breckenridge, drifting is being done with satisfactory results on the 18-inch streak of carbonate ore which was recently cut in the south crosscut at 70 feet from the 150-foot station of the shaft.——The winze sunk in the 11-foot vein of the Colorado & Wyoming Development Co. from the main tunnel lead has had considerable difficulty in sinking on account of seepage water.——Condon & Shrock, who are operating the Morning Star on Mount Baldy, above Breckenridge, by a tunnel, have opened a nice shoot of lead-silver ore.——The big new $50,000 gold dredging boat of the Reliance Gold Dredging Co., below Breckenridge, is ready to start. Drilling tests, made with a churn drill, have shown the ground which the dredge will work to be rich in coarse and fine gold.

The main tunnel of the North American Mines Co., near Frisco, is in 160 feet and is expected to cut the Red Lion vein soon. The company has twelve men at work.——At the Old Union M. & M. Co.'s property, the main tunnel is being put into shape for stoping ore for the mill, which will be started up on a continuous run next month.——The French Creek M. Co., under the management of M. G. Evans, is driving a prospect and development tunnel in the north slope of Mount Baldy, near Breckenridge.——The bedrock flume of the Mekka Co. in French gulch is approaching the elevator pit, which it will drain and convert into a convenient working space. Riffle blocks are being placed in the flume.

The Reliance Gold Co.'s dredge has started digging gravel in French gulch, near Breckenridge.——The Midnight placer, in Brown's gulch, near the Cashier, is running under the superintendency of John Sweeney. A new 1000-foot flume has been completed.——At Frisco, the Mary Verna Co. is employing fourteen men. The main work is the driving of No. 3 tunnel, from above the railroad track. This is in 175 feet, and the rock is very hard. An air compressor and machine drill will be put in soon.

Teller County.

It is reported that the final details for the commencement of driving the new Cripple Creek drainage tunnel have been perfected and actual operations will be started within the next two months. A. C. Jacquith, engineer in charge, has located the territory where the portal of the tunnel will be. There is no question of ample dumping room. It will lower the water 741 feet below the present drainage tunnel level. Two years will be required to drive it through. The total cost, when completed, will be $750,000. The El Paso shaft is to be sunk, as well as an intermediate shaft, which will permit of four headings being worked.——A big ore strike is reported on the Lady Stith on Globe hill, Cripple Creek, under lease to G. L. Keener.——Superintendent Nichols of the Midget mine on Gold hill, Cripple Creek, is working the narrow seams profitably.——The Dorothy vein, between the eighth and ninth levels of the Gold Coin mine of Battle mountain, Cripple Creek, is being worked by McBird & Higgins, who have struck a good ore body which they are stoping.——On Copper mountain, 2 miles north of Cripple Creek, R. Blanchard is working a mine in the Bill Nye claim of the Copper Mountain Co. at a depth of 180 feet.

A mining deed has been filed whereby the Katinka M. Co. transferred a part of its property to the Morning Glory G. M. Co. The deed conveying this property is without doubt the outcome of the suit brought a few months ago by the Morning Glory Co. asking $50,000 damages for ore that was alleged to have been wrongfully extracted by the Katinka Co. This suit followed closely the suit of the Morning Glory against the Mary McKinney, which suit was settled by arbitration. The ground transferred covers the Aileen-Katinka vein within the surface boundaries of the Aileen, August Flower and Chicken Hawk claims.——The lessees oper-

ating on the Unexpected claim belonging to the Central Con., near Windy Point, are working in ore and sending out occasional shipments. —— Jenkins and associates, operating Block 251 of the Stratton estate's property, on Bull hill, are breaking 4 feet of ore at a depth of 100 feet.——W. R. Rock has sold his holdings in the Gold Sovereign Co. of Cripple Creek to A. Rapp and associates.

Sinking is to be resumed at the Nugget shaft of the Legal M. Co. by R. M. Lesher of the Kimball Investment Co. Work was discontinued two months ago at a depth of 300 feet on account of water. The recent discoveries in the Mary Nevin, north of the Nugget, have revived interest. Preparations have been made to handle the water. ——The Irene Leasing Co. proposes to crosscut east from the shaft of the Prince Albert, on Beacon hill, Cripple Creek.

The effort on the part of the mine owners of Cripple Creek district to weed out ore thieves and questionable assay shops took a new turn when several operators, whose names are being temporarily withheld, caused warrants to be sworn out against ten assayers—five in Cripple Creek and five in Victor. Each is charged with aiding and abetting the theft of valuable gold ore from the various mines in the camp. The mine owners believe that there is a well organized gang of ore thieves operating in the district and that the assayers who are accused have been acting as "fences." The operators say that at least $1,000,000 worth of ore is stolen from the mines every year.

IDAHO.

Blaine County.

J. Peterson, managing owner of the Idaho-Muldoon mines at Muldoon, has bought machinery for a concentrating mill of fifty tons daily capacity. He expects to start the mill by October 15. The mill is to be composed of a rock breaker, rolls, screens, sizers and tables. No jigs are to be used, and it is to be operated wholly by water power.

Boise County.

Manager G. Z. Edwards expects that the new cyanide plant at the Lincoln mine, near Pearl, will be finished by September 1.——It is reported that the Iowa G. M. & M. Co. has purchased the Gold Hill mine at Quartzburg.——A roller mill and cyanide plant are to be built on the old Gold Hill dump.

Custer County.

The Lost Packer M. Co. at Loon Creek, west of Custer, expect that the new 100-ton smelter will be completed by September 1. The company has constructed over 20 miles of wagon road during the past year. J. A. Czizek is manager.——The Mount Estes M. Co., of which J. A. Czizek is also manager, is working the Montana on Estes mountain, 7 miles northeast of Custer. They are running a tunnel to tap the vein and expect to tap it in about 460 feet. The tunnel is in 450 feet. The machinery has been received and is being set in place. Most of the mines in this part of the country have been worked only to the water level.

Elmore County.

The Tahoma mill at Atlanta is being overhauled. It is expected that ten stamps will be operating by August 15, and twenty more are to be put in. J. C. Biedelman of New York is testing the ores from the Tahoma and General Petitt as to their adaptability to the cyanide process.

Idaho County.

President Nevin, of the Iron Springs M. Co., corroborates the report of the rich strike on the White Rose, on Rapid river, in the Thunder Mountain district. An engine and hoist have been placed on the shaft and sinking is in progress.

A. M. Ringeling, in charge of the Silver King mill at Warren, reports that the Silver King has ordered pan amalgamators and will put them in. This has been necessary to save the values. The losses which were being sustained has caused the stamps to be idle all this season, but twenty men have been kept busy by Manager L. C. Massie, putting in ore chutes, raises and overhauling the mine.——At the Keystone, where Mr. Ringeling also had charge of the milling, the 2-stamp mill has been running steadily.——R. and C. Lockwood are opening new placer ground at the head of Willey gulch, near Warren.

Shoshone County.

The dredger which began operations on the ground at the mouth of Trail creek, Delta, has reached the upper end of the company's ground, having carried up a breast of ground between 200 and 300 feet wide. It is now making the turn to come back.——The Charles Dickens lead mine on Moon gulch, below Osburn, is being worked, with A. B. Gritman in charge.——The Success M. Co. of Wallace have finished a connection in the old Granite mine between Nos. 2 and 3 tunnels. A winze had been sunk in ore from the No. 2, which is 250 feet from the surface, while the No. 3 is 413 feet below the No. 2. For the purpose of providing a proper circulation of air and of permitting the working of the mine through the No. 3 tunnel, a connection was necessary. An upraise was started from the No. 3 to connect with the winze, which was full of water. This has been completed in safety. C. F. O. Merriam was the engineer and O. Linn the foreman.

The California Con. mines on Gorge gulch, Nine Mile creek, 2 miles from Wallace, are being operated under bond by the Pittsburg Lead M. Co., with A. D. Marshal as superintendent and manager. At present the No. 3 level is being opened up to furnish ore for the 200-ton mill, which is connected with No. 3 level by an aerial tram. When No. 3 has been opened up work will be resumed in the No. 4 level, which is now in 1700 feet and intended to be the main working tunnel. The mill and tramway are being overhauled and improved.——A large body of lead-silver ore has been struck at a depth of 400 feet in the shaft being sunk to connect No. 5 and No. 6 tunnels of the Morning mine at Mullan.

Washington County.

C. H. Denison, superintendent and manager of the Iron Springs mine at Iron springs, reports that work is being done on four claims with fifty men. Work is to be started on the new cyanide plant soon. It is reported that the Iron Springs Company has secured the Rankin mill, of which J. D. Thorn has charge.

ILLINOIS.

The Illinois State Bureau of Labor Statistics has completed the redistricting of the State into nine districts. Under the old law there have been seven mining districts in Illinois. The last Legislature passed a law making the districts ten in number and the bureau has completed the redistricting. Only the coal producing counties are given and the new arrangement is as follows: First district—Grundy, Kankakee, La Salle, Will. Second district—Bureau, Henry, Knox, Mercer, Rock Island, Warren. Third district—Livingston, Marshall, Peoria, Putnam, Stark, Woodford. Fourth district—Fulton, Hancock, McDonough, McLean, Tazewell. Fifth district—Edgar, Macon, Vermilion. Sixth district—Brown, Cass, Logan, Menard, Sangamon, Schuyler. Seventh district—Calhoun, Christian, Green, Jersey, Macoupin, Montgomery, Morgan, Scott, Shelby. Eighth district—Bond, Madison, St. Clair. Ninth district—Clinton, Franklin, Hamilton, Jefferson, Marion, Perry, Randolph, Washington. Tenth district—Gallatin, Jackson, Johnson, Saline, Williamson.

MICHIGAN.

The production of the Copper Range Con. Co. for June decreased 10.000 pounds of copper, as compared with the June, 1904, production. In June, 1905, the three mines of the company produced 4,534,000 pounds of the metal, as against 4,544,000 pounds the year preceding. The Champion production was 1,838,000 pounds.

MINNESOTA.

Aitkin County.

Immense iron ore deposits are being prospected in the Cuyuna range, near Deerwood. Shafts are being sunk as the result of bore hole indications. Work is being done by the Oreland M. Co., under the direction of Cuyler Adams, the discoverer of the range. Pickard, Mather & Co. of Cleveland, Ohio, have started a shaft on land leased from the Oreland Co. The course of the belt, as indicated by the magnetic needle, is covered with an alluvial deposit 40 to 180 feet deep. The ores thus far discovered are non-bessemer, high in phosphorus, free from sulphur and titanium and not excessive in silica. Some manganese is found.

MONTANA.

Granite County

In Garnet district P. Mussigbrod of Warm Springs is giving forty lessees work on his property. —— S. I. Ritchey, owner of the Nancy Hanks and Tiger mines, near Garnet, shipped from the Tiger side of the Nancy Hanks last month a carload of ore that yielded $20.000.

J. H. Miller of Phillipsburg has taken over the Londonderry mine, in the Smart Creek district, on a lease and bond for California capitalists whom he represents. The mine has been owned by W. E. Albright. Development work is to be started at once.——Development work has been started upon the Copper State and Red Metal mines, in the Smart Creek district, by the Butte interests, which recently assumed control of these properties upon a $50,000 bond. The sinking of a shaft has started, with three 8-hour shifts.

Jefferson County.

Edwards Bros. have taken a lease and bond on the Atlanta, on the range between Cataract and Wickes. They are unwatering one of the shafts and will then crosscut to the lead from the 130-foot point.

Lewis and Clarke County.

The report of the Montana M. Co. of Marysville shows that crushing at the Drumlummon mine during the past year amounted to 6096 tons, as compared with the normal crushing of 80,000 tons of five years ago. The cleaning up of this worked-out mine is going on as before. The tailings plant yield has been steadily falling in value for several years, and while five years ago the tailings used to produce a value of nearly $3 per ton, they now yield but $1.99, and produce a net profit of 80 cents per ton, as against nearly $1.35 per ton.

Madison County.

A company has been formed to develop the Mountain Cliff mine on Mineral hill, near Pony. A tunnel is to be run from the Fitzgerald Fraction to open up the Mountain Cliff vein.——H. Walter, owner of the Yellow Mountain claims in Potosi canyon, near Pony, has bonded them to a Butte company, who intend to put in a concentrator at the mine and treat the ore at the property.

The Lennstrende-Buck Co. have the machinery, stamps, battery, etc., on the ground at their mine beyond the Garnet. The timbers for the frame work are being hauled for the 5-stamp mill. —— The Big Four M. Co. are to resume operations near Pony. This property is owned by A. J. Walrath of Bozeman and C. Vanderhook. A. J. McCormick has charge. An 800-foot tunnel is to be driven to crosscut the veins at a depth of 600 feet. —— The Clipper-Boss Tweed property at Pony, under lease to Elling & Morris, is shipping ore averaging $40 per ton to the smelter at East Helena. The great body of the ore is milling and is sent to the Strawberry 10-stamp mill above Pony.

Silver Bow County.

(Special Correspondence).—The Butte district in June produced a total of 31,290,000 pounds of copper, an excess over the May production of 3,690,000 pounds, or on an average of 123,000 pounds a day more than the daily average for May. It was a new record for Butte mines, every one of which was run to full capacity. The grade of ore shipped was of a generally higher value, and the new North Butte Company more than doubled its output. The following are the figures of the daily output of ore and the amount of copper produced therefrom:

	Tons of Ore.	Pounds of Copper.
Boston & Montana	3,000	225,000
Anaconda, Washoe, Parrot, Trenton	7,000	490,000
United Copper	2,000	140,000
Clark mines	1,500	108,000
North Butte	800	80,000
Totals	14.300	1,043,000

Butte, July 17.

The Pittsmont smelter at Butte has been started with 9000 tons of ore in the bins. Manager R. L. Baggaley has been stoping in the Donner vein since June 27. The flow of water in the lower workings has been controlled by the two new electric pumps.——Work has been resumed at the Jennie Dell mine at Butte.

NEVADA.

Esmeralda County.

A fire at Columbia, July 15th, destroyed business property worth $100,000. The origin of the fire is unknown.

The Diamondfield M. Co. and the Black Butte Co. of Goldfield have consolidated to avoid a lawsuit, as the ledges of the two companies dip towards each other.

Lincoln County.

The Good Springs Smelting & Developing Co. has been formed under the laws of Massachusetts with A. H. Gates, Chicago, president; G. F. Nealley, Haverhill, Mass., treasurer; these with P. A. Dyar, G. W. Hinkley and J. W. Wharton, all of Boston, and C. H. Raymond and C. E. McCarthy of Haverhill constitute the board of directors and the incorporators.

Washoe County.

A rich strike is reported in the Emma L mine, north of Olinghouse. The Emma L strike was made at the 195-foot level. D. Wetmore and W. Golding are owners.

OREGON.

Baker County.

J. A. Panting, owner of the Gold Hill mine at Durkee, is making arrangements for starting work.

Instead of building a new 10-stamp mill below the old millsite of the Connor Creek property, it is stated that P. Basche of Baker City, who has a bond on the mine, is remodeling the old plant, having added ten additional stamps, taken out twenty-five of the old light stamps and put the remaining ten in shape for effective work. As the present mill is above the portal of the lower crosscut, from which ore will be delivered, an elevating device will be necessary to deliver the ore into the mill bins.——The Oregon Lime & Plaster Co., 5 miles from Huntington, is employing thirty men and is handling a heavy tonnage of lime and gypsum.——Ed. Rea and E. P. Torrey have taken the contract for building a cyanide and concentrating plant to handle the Bonanza mill dump, contemplating both concentrating and cyanidation. The tailings from the Bonanza have been impounded for two years and will make a reserve for work. Manager Albert Geiser of Sumpter has twenty-five stamps dropping.

Crook County.

Building has commenced in the construction of the Almaden mercury plant, 28 miles from Prineville. The Almaden Furnace Co. has been organized to do this work, which is under the direction of C. Fitzgerald. The plant will have ten tons capacity. The New Almaden G. & Q. M. Co., which owns the mercury property, will resume development when the furnace is in working order.

Douglas County.

At a meeting of the Bohemia Mine Owners' Association steps were taken to interest smelter men in Bohemia camp. One mining man stated that in case interested parties put up a smelter he would sign a contract to deliver fifty tons of ore per day. With this amount of ore from one man, it is considered an assured fact that a smelter would pay if once put in operation. Men who are now doing nothing with their properties would proceed to active development. A new wagon road is surveyed into Bohemia and work will be commenced soon. The road extends from Glenwood, on the county road, to Shane's Saddle, and will open up a very productive part of Bohemia. The road is not over 8% grade in any place, and is 2⅛ miles long.——It is reported that the Combination mine, on Martain creek, owned by Sheridan & Co., will be reopened soon. This property consists of seven claims in the southern part of the district, and some very rich ore has been taken out. The ore is base and a smelting proposition.——The Great Eastern property, on China, Bear and Sailor's Gulch creeks, consists of nineteen claims and shows bodies of high-grade smelting ore. This mine, from its No. 1 group on China creek, could ship twenty tons of ore to the smelter per day. A wagon road up Martain creek, a distance of 3 miles, would put this property on a shipping basis, as there are large ore reserves.——The Star Con. property is 4 miles up Martain creek. A 5-stamp mill is on the property, but is not running. The ore goes into a sulphide as depth is gained, and it is said to be a good cyaniding proposition.——The Twin Rocks property of eleven claims, 3 miles south of Bohemia, is owned by Illinois and Oregon men. Lewis Hartley is in charge.——Manager F. J. Hard has started the 10-stamp mill of the Vesuvius mine at Bohemia. The plant was thoroughly overhauled before the stamps began to drop, and the aerial tram was retensioned after the winter's idleness, so that the mechanical plant is in shape for best results.

Jackson County.

The granite quarry on Griffin creek, 4 miles east of Jacksonville, owned by E. P. Geary of Portland, has been leased by S. and W. B. Penniston of Ashland, who will open it and begin quarrying rock. The granite is light, mottled with gray, and takes a high polish.——J. M. McPhee, one of the new owners of the Alice property, near Gold Hill, is arranging for heavier work. The Alice is on Galice creek, near the Foots Creek district.

Malheur County.

In the Mormon Basin district the Summit M. Co. started its new stamp mill on July 5, only five stamps out of ten being run. The mill is crushing ore taken from the ledge opened up last fall.——The Tarbell group, which took out ore during the winter and spring, is treating it at the Commercial M. Co.'s mill near by.——W. S. Newberry, manager of the Morning Star group, in Mormon basin, intends to resume operations soon.——At the Gold Coin in Mormon basin, on the summit of the divide between Rye valley and Burnt river, Ayers & White of Pendleton and Durkee of the town of Durkee are building a 10-stamp mill.

SOUTH DAKOTA.

Pennington County.

The Canton M. Co., northwest of Hill City, has closed down its mine for the present. The main shaft is now down 150 feet. Logs are being cut for further mine timbering and for the lumber for the mill, the foundation of which is almost completed. A. Anderson, manager, has placed an order for a 35-ton mill. Work will be resumed when it is put in.

UTAH.

Grand County.

J. R. Emmitt of Moab and Mr. Butterwood of Salt Lake City have been arranging with the stockholders of the Moab Irrigation Co. for the use of the water of the North Fork of Mill creek. They propose to take the water out on Wilson mesa, 20 miles above Moab, there use it for placer mining and then return the water to the regular channel, so it can be used for irrigation purposes. They agree to return as much water as they take out, and also to build a reservoir at some convenient place above Moab, where the water can be settled. The reservoir, besides being a place for settling the water, will enable the irrigation company to store the early water and use it late in the season, when water is scarce.

Juab County

W. Ball, D. A. Depue and J. T. Hayes have taken a lease on the dump at the Eureka Hill mine at Eureka. They will begin work with teams and scrapers, and will remove a few feet of waste in order to reach the low-grade ore which was put on the waste dump many years ago. They believe they can ship ore from this dump at a profit. There are a number of leasers in the upper workings of the Eureka Hill. The Eureka Hill M. Co. is not doing anything with the lower levels of the mine at this time, but may decide to lease the entire workings.

Salt Lake County.

W. J. Craig, manager of the Kennebec mine at Alta, has started work on the intermediate tunnel which is intended to tap the ore bodies under the old workings of the mine. Work will be continued in the lower tunnel.

The Bingham Con. M. Co. has determined to construct a reverberatory furnace and roasting plant to handle the fine ore and flue dust, which has previously been a waste product at the company's location. The plant, the plans of which have been matured by the company's engineers after a long study of the various similar plants in other copper producing districts, is also expected to do away with the flue fumes nuisance, with which all the companies have more or less trouble, because of the damage done neighboring ranches. The plant will cost $60,000 and construction will be started immediately. The company has had the construction of this plant under consideration for a long time. The officers of the Bingham have made a thorough inspection of the similar plants of the Amalgamated Co. in Butte and will have the advantage of the advice of the engineers of that company in the erection of the concentrator. When the matter was first brought under consideration it was determined to have the roasting plant at the mouth of the Mascot tunnel, but this was changed later and it is now the plan to have the roaster at the smelter site. At the Dalton and Lark all the ore is being moved through the tunnel, which is connected with the present openings by short drifts. This has made a difference of almost $1 a ton in the cost of handling the ore. Ore bodies have been opened up in the lower workings that give promise of permanency and good values. The Eagle & Blue Bell has shown improvement.

The Phœnix mine at Bingham is shipping thirty tons of first-class ore daily. From sixty-five to seventy-five tons of milling ore is being taken out daily and is being stored at the mine awaiting treatment at the Kempton mill. The winze from the tunnel level has been sunk 65 feet. Superintendent Gebhardt is working three shifts, employing sixty men.——Superintendent L. G. Morser of the Mystic Shrine at Bingham reports improvement in the ore body in the Shrine, as it grows larger with development. The character of the ore is also changing, carrying less lead and more copper.——The Utah C. Co. have built a dam in the Jordan river to impound their tailings and prevent damage to land below the mill.

Summit County.

Manager Turner of the West Quincy property at Park City reports that the drift now being run from the Little Bell shaft is in 2300 feet and has been in West Quincy ground for some time. It is expected to tap the shaft in two months. So far no trouble has been experienced from water, and when completed the drift will drain the mine so that there will be no further expense of pumping.

Ed. Kopp of Park City has taken a lease on the Ontario tailings dump below the mill, and intends running it all through the mill to secure the values which it contains. When work was first commenced the tailings were hauled to the mill by horse power, but Kopp has put a 5 H. P. electric motor near the mouth of the mill tunnel, together with a small engine, by means of which the tailings will be hauled to the tunnel entrance.——At the Nelson property in Elkhorn district, near Park City, the new shaft is down 50 feet. J. Nelson has charge.

Tooele County.

The Sundown, the Bethel and other mining properties in Camp Floyd district have been sold to Denman Blanchard of Boston for $37,500. The sale was made under an order of sale in the suit of Mercantile Trust Co. vs. Overland M. Co. et al. The property is equipped with a fine milling plant and is near Sunshine.——The Stockton G. M. Co. has secured rights in the canyon below their mill, so that the tailings controversy has been settled. Manager Trenam is also building settling ponds to prevent the tailings running down the canyon. When these are finished the mill will be started.

WASHINGTON.

Cowlitz County.

R. C. Lange, secretary of the Spirit Lake Power & Mining Co. of Chehalis, has returned from a trip to Europe, where he placed 200,000 shares of stock in his company. He intends to begin development on the shores of Spirit Lake, near St. Helens. It is intended to put in a water power plant on Union creek and put in an air compressor and drills and drive 3000 feet of tunnel.

Stevens County.

The engine and five cars for the Chewelah Copper King M. Co. are transporting ore from the mine to the railroad.

WYOMING.

Carbon County.

B. W. Law, manager of the Four Mile Dredging Co., near Saratoga, has stopped work because the ground containing the gold has become exhausted and the values too low to keep the big dredge working.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Boundary District

Boundary ore shipments for the week ending July 15 were: Granby mines to Granby smelter, 12,522 tons; Mother Lode to British Columbia copper smelter, 2720 tons; Mountain Rose to British Columbia copper smelter, 198 tons; Emma to Nelson smelter, 231 tons; Oro Denoro to Granby smelter, 99 tons. Total for the week, 15,770 tons; total for the year to date, 492,243 tons. Boundary smelters treated this week as follows: Granby smelter, 12,850 tons; British Columbia copper smelter, 3435 tons; total for week, 16,285 tons; total for the year to date, 504,250 tons.

A Greenwood report of July 15 says: At the British Columbia Copper Co.'s smelter, shortly after a new head feeder had taken his position supplying that vacated by the regular man off on holiday, several men of the day shift succeeded in inducing some of the furnace feeders of one of the furnaces to quit work on the ground that the new man was taking another man's job. As one furnace cannot provide enough matte for a converter, the better sense of the men from the tamping floor prevailed and they, with several of the regular furnace force, assisted by Mr. McAllister and Mr. Williams, the assistant superintendent, drew off the furnace and cleaned up. To-day the smelter closed down, although a good ma y men are at work. The mine work at Mother Lode is going on as usual and furnaces will be blown in again as soon as new men can be obtained.

It is reported that good ore has been reached in the 400-foot tunnel of the Seattle mine, near Greenwood, being operated under bond by W. T. Hunter. This 3-foot vein was struck about 340 feet from the portal.——On or about the 1st of August, it is the intention to blow out all six of the furnaces at the Granby smelter at Greenwood for two or three days, for the purpose of connecting up the two new and larger furnaces now being installed, as well as the new flue dust chamber and new smokestack.

The deal by which the Dominion Copper Co. financed the Montreal & Boston Consolidated is as follows: The Montreal & Boston found that it owed $186,789 to the Dominion Copper Co.; $90,000 to two trustees for money advanced, and other liabilities of $43,000, making a total of $320,000. This sum could not be raised by sale of stock, so an arrangement was made by which the Montreal & Boston sold to the Dominion Copper Co., exchanging shares on the basis of one of the Montreal & Boston Co. for one of the Dominion Copper Co. In this way the Dominion Copper Co. will take 1,242,724 shares of the Montreal & Boston, share for share, through the trust company. The Dominion Co. agrees to assume and pay debts of the Montreal & Boston, and to do this and provide a working capital will issue $1,000,000 in bonds bearing 6% and running ten years. Shareholders who subscribe will get them at 90% of the par value; in addition will be given two shares of the Dominion Co. as a bonus. Thus the buyers of $700,000 bonds, all of the bonds to be placed on the market, will receive 1,400,000 shares of Dominion Co.

Cassiar District.

An unverified press dispatch says that silver ore, running $1100 to the ton, has been struck on property being opened on Windy Arm, 6 miles from Carcross, in the Atlin district. The management has sent to Tacoma for an aerial tramway to cost $125,000, which will be used in conveying the ore from the ledge to the steamers on the lake. The steamers will carry the ore to the White Pass trains at Carcross, whence it will be shipped by rail to Skagway, thence by ocean steamer to the Selby and Tacoma smelters. The Atlin mining division is all that part of British Columbia north and west of the divide between the watersheds of the Taku river on the south and east and that of Atlin lake on the north and west.

East Kootenay District.

In addition to mining in the stopes of the Sullivan mine at Kimberley, from which 140 tons per day is taken, J. Finley is prospecting and is keeping his development work ahead. —— For the month ended June 30 the output of the St. Eugene mine at Moyie was 2750 tons of concentrates. There are 300 men on the payroll. The machinery for the new 30-drill air compressor is being put in and an effort will be made to have it running by August 1. The company is behind with development work, and as soon as this machinery is ready to run an additional 100 men will be put to work. This will bring the wages paid monthly up to nearly $40,000.

Rossland District.

Figures showing the payroll of Rossland for July prove that the disbursement for labor was $144,400 during that time, of which $83,200 was for the mines. There is great activity in Rossland at present, and the promise for the remainder of the year is brighter, as much new work is in progress.

J. Labarth, superintendent of the Trail smelter, has started one of the lead stacks. Ore from the St. Eugene and other mines are expected to keep the lead stack in steady operation. Labarth states that the lead refinery will soon be enlarged to turn out fifty tons of pig lead a day. There is a growing market for the lead. The corroding works in Montreal consume considerable, while the larger portion is marketed in Japan and China.

Slocan District.

Slocan ore shipments for the week ended July 15 were: Silver-lead – Payne, 22 tons; American Boy, 21; Last Chance, 20. Zinc, 240 tons. —— C. Hanson has been working on the Bessie property on Lemon creek, near Slocan City. —— Mining conditions have taken an encouraging look throughout the Silverton district. Leasing is coming more into vogue. Test trials are being made on the Emily Edith ore at the Wakefield mill, and if successful will be the basis for more extended work on the properties under control of Mr. Davys. On the Baby Ruth, P. Grant and R. Spencer are sacking ore. For the short time these lessees have been working, the property is certainly paying rich.

Vancouver Island.

(Special Correspondence).—Tyee Copper Co.'s smelter ran 13 days and treated 1988 tons of Tyee ore during June, giving a return, after deduction of freight and refining charges, of $30,950.

Duncans Station, July 15.

MEXICO.

The recent action of Mexico in abolishing the free zone along the boundary line is having an injurious effect on the merchants, both of Mexico and the United States. Mining interests are much affected, for where machinery was formerly admitted free of duty, now full price has to be paid. This has resulted in such a heavy increase in operating expenses that it is said that several of the large mines in Mexico near the line have been forced to shut down.

Regarding asphaltum and petroleum in Mexico, the Mining Journal says that they are found on the Gulf slope, in the States of Tamaulipas, Vera Cruz and Tabasco, while on the high plateau they are found in Mexico, Puebla, Guanajuato and Queretaro, and on the Pacific slope in Oaxaca, Morelos, Michoacan and Jalisco. On the shores of Laguna Madre, and on those of the Morelos, San Andres and Champoyan lakes, petroleum flows plentifully from many springs, and mineral tar and asphaltum frequently run in a molten state over the ground under the action of the sun's rays, the same phenomenon occurring at many points along the margin of the Tamesin river. Vera Cruz contains these mineral compounds in perhaps greater abundance than Tamaulipas, the principal beds lying near Jalapa, in the municipality of Panuco, Minatitlan of the Jalacingo canton, near the bridge called Quilate, municipality of Atzatlan, and in that of the Tlapacoyam, on the Vega lands. The asphaltum deposits in the canton of Jalapa are at a short distance from the Chicuasi Rancheria, in the municipality of Artopam. They are of the basaltic formation, which predominates throughout the canton of Jalapa, and in some spots the clefts in the basalt—vertical and horizontal alike—serve as outlets for the tar, which in great quantities covers the rocks. Petroleum is also visible in some cavities of the rocks, where it is mixed with water. At the town of Moloacan there is asphaltum on the margin of an arroyo tributary to the Coatzacoalcos. In Aginche and Copacao, of the jurisdiction of Panuco, in the same State, are large beds of asphaltum, and others in Tanelum. There are petroleum springs in Chinameca, near Gila lake; in the hacienda of Chapapote, on the banks of the Tuxpan river, and at many other points. Asphalt and petroleum are abundant in Tabasco, one of the principal deposits being at Estancia Vieja, 12 miles from San Juan Bautista, where the asphalt and petroleum are mingled, mineral tar predominating. Petroleum of a grayish color is plentiful in the district of Macuspana. Tests of petroleum taken almost from the surface have yielded 50% of lubricating oil. These springs are on the shore of a small lake which empties into the Macuspana river, and the latter into the Grijalva, so that the oil could be easily transported, both lake and rivers being navigable for vessels of small draught. Near Macuspana, at Las Templaderas, asphaltum is also plentiful, and by pressing the ground with the foot it oozes to the surface through numerous cracks. Northeast of Macuspana, at Tortuguero, under a thin layer of sulphate of strontium, fluid petroleum is found so clear in quality that it might be taken for naphtha. This liquid is very inflammable, for when making some experiments it took fire the moment a flame was brought near it. The region of mineral oil in Tabasco extends over 62 square miles. Chiapas also possesses asphaltum beds, the best known being those of San Diego de la Reforma, San Pedro Chenalho, San Miguel Mitontic and Villa de Teopisca. The most abundant, as well as the purest, is that at Chenalho. Among the petroleum springs of the central tableland, mention may first be made of those in the villa of Guadalupe Hidalgo, distant about half an hour's journey from the national capital. These springs have never been utilized, for the reason that they are situated in the very streets of the town, and that the indemnity paid for working them would probably be more than would be justified by the returns. Puebla has petroleum springs and beds of merchantable asphalt, of which the most valuable are in the district of Tetela, municipality of Tenampulco, on the Coroneles plateau, in the district of Huanchinango, in the municipalities of Jalpan and Tehuantepec, and on the hacienda of San Diego. Petroleum is found at La Estrella, north of Puebla, on the San Diego hill. Guanajuato has good mines of asphaltum, and it is said that others exist in the district of Caderyta, in Queretaro. There are productive springs of petroleum in Oaxaca, the oil being in places very clear and transparent, especially in the district of Pochutla. The petroleum deposits of Pochutla cover a surface of nearly 50 square miles, and some places the oil runs freely over the ground. In the district of Jonactepec, State of Morelos, petroleum shows itself at various points. Both asphalt and petroleum exist at a number of places in Michoacan, the chief one being Cucumatlan, in the jurisdiction of Sahuayo. The picturesque lake of Chapala, in Jalisco, contains petroleum springs, and on its waters float layers of asphaltum. In Colima, about 42 miles from the capital, have been found beds of a substance which seems to be asphaltum in some places, and in others bituminous coal, burning with an intensely blue flame and exhaling the peculiar odor of asphaltum. In the barranca of Zacualpan is also a mine of the same substance.

Jalisco.

At the annual meeting of the Boston & Mexico Gold & Copper M. Co., whose properties, consisting of thirty-two claims, are near Ameca, C. P. Winslow, Boston, was elected president; J. G. Peters, Boston, vice-president; W. H. Loughrey, Boston, secretary, and E. Gilmore, North Easton, Mass., treasurer. It was stated that there was sufficient money in the treasury to warrant sending the superintendent, E. N. Everett, to resume work upon the property.——Copper-silver mines near San Antonio de las Moran, in the Ayutla district, are to be worked by the Paloma M. Co. The principal mines of the group are the La Puerta, La Falda, Chapuza and Providencia. The mines were formerly the property of E. Fitzpatrick and W. W. Dodd, who are now stockholders in the new company. Considerable ore has been shipped from the properties and a concentrating plant with a capacity of twenty-five tons was built some time ago. The company expects to put in reduction machinery.

Sonora.

(Special Correspondence).—The San Bernardo M. Co., which is the owner of the Santo Domingo mine in Aduana, near Alamos, J. R. Hendra, superintendent, have the new boiler, an engine and gallows frame in place and in working order. The shaft has been drained to the 200-foot level and timbered where it was required. A new ladderway has been put from top to bottom and the sinking of the shaft commenced. The shaft will be sunk 100 feet and then crosscut the lode, and then commence driving north to get under the old workings, which will require 400 feet of drifting.——The adjoining property on the north is the Zambona, owned by the Zambona Dev. Co., A. Yaeger superintendent. The work is being pushed changing the machinery in the mill and mine. The mill is expected to be in operation by August 1. —— On the south of the Santo Domingo is La Quintera, owned by a French company. —— The district of Alamos needs a railroad.

Alamos, July 15.

The La Cobriza mine, in Altar district, near Puerto, owned by W. T. Stewart and A. H. Parker of El Paso, has been sold to F. C. Emery of same city for $12,000.

Books Received.

As extracts from "Mineral Resources of the United States for 1904," the United States Geological Survey has issued "The Production of Iron Ores in 1904," by John Birkinbine, and "The Production of Tin in 1904," by J. H. Pratt.

As a part of the "Geologic Atlas of the United States," the United States Geological Survey has issued Folio 125, "Rural Valley Folio, Pennsylvania." This describes the coal, iron and gas resources and geology of a part of the Appalachian field.

As extracts from the "Mineral Resources of the United States for 1904," the United States Geological Survey publishes "Peat in the United States in 1904" by H. H. Hindshaw, "Production of Sulphur and Pyrite" by J. H. Pratt, "Production of Manganese Ores" by John Birkinbine, and "Production of Abrasive Materials" by J. H. Pratt.

Those having to do with peat and waste fuels may be interested in an exposition of their utilization as given in "Briquets and Patent Fuels," by P. R. Bjorling. The book contains many suggestions as to manufacture and materials of briquet fuels, an industry that has received some development in this country since this book was written. While the chapter on bond or binding materials may be a good guide to inventors, much of the material in the rest of the book has been superseded by recent practice and is interesting chiefly as a matter of history. It is published by the Rebman Co., 1123 Broadway, New York City.

The widespread importance of coke as a fuel has received fitting notice in a second edition of "Coke," by John Fulton. This masterly treatise presents the subject clearly and logically, omits the unessentials and appears to present all that is necessary for an understanding of the details of manufacture. The chapter on the preparation of coal for the manufacture of coke takes up the necessity for preparing coal in order to remove impurities before making blast furnace coke, and then describes the crushing appliances, with costs of the crushing plant. Both the bee hive oven and the retort and by-product saving coke ovens are fully described in construction and manipulation. This section is particularly interesting because of authentic cost statements and because it details operating plants. The present condition of the fuel briqueting industry is admirably summarized in the concluding chapter. The book is published by the International Text Book Co. of Scranton, Pa., and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of $5.

The California State Mining Bureau has issued a bulletin on "Gold Dredging in California." A history of gold dredging in California, by J. E. Doolittle, opens the text of the volume. The subjects treated are the area of dredger gravel, geology of that area and its agriculture; the yield of gold dredging for 1903; the forms, power and styles of dredgers; kinds and styles of screens, sluices, etc.; composition of the crew of a dredger; working costs; prospecting and examination of conditions and prospecting machinery; the Oroville, Yuba, Bear River, Folsom, Calaveras, Plumas, Shasta, Trinity and Siskiyou dredging districts, etc. In addition there is considerable matter with some full-page illustrations of the California State Mining Bureau. An interesting chapter in the book treats of the restoration of gold-dredged lands to agricultural uses, and claims that this is not only feasible, but profitable, and that these reclaimed lands after the dredger is through with them can be made of higher average value than before. At the beginning of this year the dredgers at work in this State were: Oroville district, 28; Calaveras, 1; Folsom, 8; Shasta, 2; Trinity, 1; Siskiyou, 2; Yuba, 2; or 44, as against 31 in 1903.

Commercial Paragraphs.

THE Ernest Wiener Co., making a specialty of mine equipment and railroad material, has opened offices at 68 Broadway, New York City.

THE Bucyrus Co. of South Milwaukee, Wis., is building forty-one steam shovels, three railroad wrecking cranes and one railroad pile driver for work at Panama.

HARRON, RICKARD & MCCONE have established a new machinery house in Los Angeles, Cal., at 164-168 North Los Angeles street, which will be run in connection with their old established San Francisco business, 21-23 Fremont street.

THE Davenport Locomotive Works, Davenport, Iowa, are publishing a series of pamphlets describing their industrial locomotives which graphically portray their salient points. Any of this illustrated descriptive series will be sent anywhere on request.

THE officers of the Crocker-Wheeler Co., manufacturers of electric motors and generators, whose main office and works are at Ampere, N. J., have been re-elected for the ensuing year. The regular quarterly dividend of 1½% has been declared and the affairs of the company are reported to be in a flourishing condition.

THE DeRemer Water Wheel Co., Denver, Colorado, have shipped to the Salida Light, Water & Power Co., Salida, Colo., three 32-inch DeRemer water wheels, strung on one shaft and direct connected to generator, provided with the DeRemer bronze cut-off hoods, and governor for regulation, designed to operate under an effective head of 400 feet and to develop 350 H. P. each unit; also a 3-foot DeRemer water wheel to the Success M. Co., Wallace, Idaho. This latter is intended to develop 75 H. P. under a 430-foot head and 100 cubic feet of water.

Latest Market Reports.

SAN FRANCISCO, July 21, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27¼d (standard ounce, 925 fine); New York, bar silver, 59½c, refined (1000 fine); San Francisco, 59½c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.00; Lake, 1 to 3 casks, $15.00@15.12½; Electrolytic, 1 to 3 casks, $15.00; Casting, 1 to 3 casks, $14.50@14.75. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £67 6s 3d spot per ton.

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.42½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¼c; pig, $4.85. London: £13 15s ℔ long ton.

SPELTER.—New York, $5.30; St. Louis, $5.18; London, £24 ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $31.40@31.60; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, ℔ lb., 35@37½c. London, £145.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@82c ℔ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.75c; San Francisco, Plumbers', 100-lb. lots, 17.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.60; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $23.00@$23.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 12c; Hallett's, 13c; San Francisco, 1000-lb. lots, 11c; 300@500-lbs. 12c; 100-lb. lots, 13c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ℔ set; 14 oz., 40s., 9¾c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2¼@2½c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5½c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 64c; cs., 69c; raw, bbl., 62c; cs., 67c; Lucol oil, boiled, bbl., 54c; cs., 59c; raw-bbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 17¼c; Astral, 17¼c; Star, 17¼c; Extra Star, 20¼c; Eocene, 19¼c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20¼c; cs., 24c; Mineral Sperm, cs., 26¼c; Deodorized Stove Gasoline, bulk, 14¼c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12¼c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

MOLYBDENUM.—Best, $2.75 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

URANIUM.—Oxide, ℔ lb., $3.50.

MERCURY.—Bichloride, ℔ lb., 77c.

TUNGSTEN.—Best, ℔ lb., $1.25.

PHOSPHORUS.—American, ℔ lb., 70c.

SODIUM.—Metal, ℔ lb., 50c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¼c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MAGNESIUM.—Pure, N. Y., $1.60.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JULY 11, 1905.

794,371.—STRAINER—J. G. Anson, S. F.
794,481.—FUEL—D. M. Balch, Coronado, Cal.
794,211 —DRIVING MECHANISM—W. J. Bell, Los Angeles, Cal.
794,275.—STARTING ENGINES—W. J. Bell, Los Angeles, Cal.
794,400.—DOOR SECURER—M. Farrell, S. F.
794,457.—RESTRAINING DEVICE—J. Gaiter, Livermore, Cal.
794,626.—COIN DISTRIBUTER—C. H. Hall, Fresno, Cal.
794,221.—BLANK TRIMMER—J. H. Haskins, San Diego, Cal.
794,303.—LEDGER SHEET HOLDER—A. D. Inglis, Sacramento, Cal.
794,230.—ELASTIC TIRE—E. Keup, S. F.
794,183.—GARMENT FASTENER—Mary E. Kintz, Tacoma, Wash.
794,238.—BOUGIE—S. L. Kistler, Los Angeles, Cal.
794,361.—WEED CUTTER—E. M. Lambson, Walla Walla, Wash.
794,461.—CHAIR—P. Mackey, Jamestown, Cal.
794,308.—CASING GEAR—E. B. Noble, Los Angeles, Cal.
794,341.—HORSE COLLAR—C. P. Randolph, Los Angeles, Cal.
794 691.—CAN SOLDERING MACHINE—G. J. Stewart, Los Angeles, Cal.
794,692 —CAN SOLDERING MACHINE—G. J. Stewart, Los Angeles, Cal.
794,476.—PUNCHING MACHINE—J. Wilderman, S. F.
37,481.—DESIGN—E. S. Cheney, Oakland, Cal.
37,482.—DESIGN—E. C. Hurlbert, St. Johns, Or.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

RESTRAINING DEVICE.—No. 794,457. July 11, 1905 John Gaiter, Livermore, Cal. This invention relates to a device for restraining insane or unruly persons without the use of the severe straight jacket apparatus. Its object is to provide a device which will perfectly restrain the persons and at the same time allow them the greatest possible amount of liberty, while preventing them from injuring themselves or others. It consists of a main body band with securing straps and buckles, wrist cuffs, straps by which said cuffs are adjustably connected with the first-named straps, ring attachments to the lower sides of the wrist cuffs, and straps by which the arms may be pinioned in a substantially extended position.

CHAIR.—No. 794,461. July 11, 1905. Peter Mackey, Jamestown, Cal. This invention relates to an improvement in chairs especially designed for children's use. Its object is to provide a chair for the use of children, which is capable of being converted for a variety of different purposes. It consists of a base having an upwardly extending back, an upper seat portion having a slot or channel adapted to fit over said back and cleats extending down upon each side of the top of the lower portion, said cleats having the lower edges curved to form rockers.

MINING AND SCIENTIFIC PRESS.

Whole No. 2349.—VOLUME XCI. Number 5. SAN FRANCISCO, CAL., SATURDAY, JULY 29, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Open Cut Mining.

A frequent inquiry is how cheap can mining be done, or how low a grade of ore will pay. A moment's thought will make it apparent that it altogether depends upon circumstances what grade of ore may be mined and treated at a profit. A small vein of ore must necessarily be high grade to pay the cost of mining alone, though the cost of milling or smelting may not be so greatly in advance of the cost of treatment of the low-grade ore from a large vein. In fact, the cost of treating a free-milling gold ore from a small vein would in most instances be lower than the cost of treatment of a complex ore from a large vein. It is evident, therefore, that the great difference in cost is usually in mining the ore and not in its treatment after it has been mined and delivered at the metallurgical works. When contemplating the probable cost of mining, there are so many factors to be considered that it is not always possible to tell within narrow limits what the cost will be. Usually the cost is diminished somewhat after mining has been thoroughly established and various methods tried. The system of mining at first adopted may be a proper one, but in most cases the careful superintendent can see where an improvement may be made or a cost lessened. The tonnage daily required by the mill is carefully gauged and the proper number of men are employed to furnish this requisite supply. More men than are necessary increase the cost of mining; and fewer men than this number are no advantage, and likewise cause an increase in expense per ton. The human capability of a man is limited; he may be urged to perform unusual tasks for a time through substantial encouragement in the way of a bonus or other reward, or he may exert himself for a time to a greater degree than he is able to maintain for other reasons. Occasionally men on opposite shifts, through friendly rivalry, make an effort to outdo each other in the amount of ore broken and sent to mill. These friendly contests are commonly encouraged by the management. The cheapest mining can undoubtedly be done by the open-cut method. Those unfamiliar with open-cut methods usually conceive that it can only be carried on in a vein or deposit of enormous extent, but the open-cut system can be advantageously employed in veins of comparatively narrow dimensions—30 feet, or thereabouts—by providing underground stopes into which the overburden of the hanging wall may be sent for filling, thus making cheaply available a larger amount of vein rock at low cost. The open-cut system is also applicable to flat sheets of ore, as shown in the accompanying engraving. Here a sheet or shoot of gold ore, lying almost horizontal, is being blasted down in amounts from 500 to 3000 tons at a round and the ore loaded into cars which are made up into a train and hauled to the mill by a locomotive. If the deposit were of greater thickness it would perhaps pay to run a tunnel at a lower level and connect it with the cut by a series of raises, so that the broken ore could be handled by gravity, but the comparatively limited vertical extent of this ore body does not justify such method. It is not unlikely that the cost of handling the broken ore might be reduced somewhat by the employment of a steam shovel. Here again must be considered the cost of installation and also of operation, and these questions must be determined by the magnitude of the deposit or vein. If there is a very large amount to be handled it would doubtless pay to put in a steam shovel; if the quantity be small it would probably not justify the expense of the steam shovel for the first cost of the plant and the operating expense may absorb all that might otherwise have been profit.

Mining by the Open Cut Method in South Dakota.

Pumping Water for Placer Mining.

There are instances where water may be pumped from a large body of water or a well for placer mining and the operation still prove profitable. Where the height and distance to which the water is to be delivered are not too great, this method of securing a head is perfectly feasible. The accompanying illustration is that of a dismantled pumping plant situated on the bank of the Colorado river, in Picacho basin, California, about 30 miles north of Yuma. Here nearly half a million dollars was expended in pumping machinery, shaft sinking on the bank of the river and the construction of a pipe line. At the head of this line, 5 miles back from the river and 500 feet above it, a wooden stave tank was built, having a capacity of about 4000 gallons. Into this the water was pumped in a feeble, small stream, the pumps being unable to meet the requirements. As a consequence, the entire scheme was abandoned—another failure due to inefficient engineering advice.

Pumping Water for Placer Mining.

THE long continued dispute between the mine operators and the miners in Illinois coal mines over the "Shot-firers bill" was finally submitted to Judge Gray as arbitrator on the disputed points, and he wisely decided that the operators and miners should share the expense. Under this decision the operators must pay the cost of inspection and the miners must pay the cost of firing the shots. As a result, the mines are again resuming operations.

THE relative value of pure potassium cyanide, sodium cyanide and the double salt of sodium and potassium cyanide, in the cyanide process, is now receiving considerable attention. Sodium cyanide contains cyanogen to the extent of 125% to 130% of that measured in terms of potassium cyanide, but some cyanide operators who have used sodium cyanide now say that the extraction and general results are less satisfactory with this chemical than when potassium cyanide or the double salt of potassium and cyanide is used. There are others, however, who speak strongly in favor of sodium cyanide. It is not unlikely that the different classes of ore that these operators have had to deal with are in a measure responsible for the variable results with the different chemicals employed.

WHILE a mining engineer who has a commission to make a mine examination for a client may expect that those employed about the property will undertake to place the situation in the best possible light, it is not incumbent upon the engineer to accept as truth all that is told him, nor to discredit all he hears, but to ascertain for himself the facts. It is not a bad idea on the part of the examining engineer to cultivate the foreman or some other person in authority at the mine and to learn where the rich places are, if any exist, and to then investigate the poor ones on his own account. Experience in mine examination has taught that it is unsafe to accept any statement that may be made by any person concerning the property, for one cannot tell what influences may be back of any statement, either for or against the mine.

The Business Man as a Mining Engineer.

Success in business is sometimes responsible for men overestimating their capacity to manage the affairs of a business with which they are not familiar. This is not infrequently the case in mining. It is not an uncommon thing to see a number of business men associate themselves for the purpose of purchasing and operating a mining property, and this association often takes corporate form. A mine is bought, a superintendent and manager appointed—usually one of their number or some one whom they all know to possess business experience, and who has made a success of merchandising or, perhaps, in politics, but whose mining knowledge is confined to such paragraphs as have come to his notice in the daily papers. The newly created mine manager provides himself with a copy of the miner's "vade mecum," or a text book or two, and starts for the mine, where he is enabled to size up the situation with rare judgment, born of business experience, aided by an industrious perusal of the books he has bought, while en route to the mine. As few mines are of consequence without a mill or a smelter, he solicits bids from several manufacturers for the construction of a "first-class, up-to-date" mill. Having accepted one of the bids, the lowest, and placed the order with the mill founders, he turns his attention to the mine. A tunnel, perhaps, exposes a vein apparently 100 feet wide. This, he is satisfied, should be able to supply a large mill with an enormous amount of ore for years. Some more development work is done and it is then discovered that there is another outcrop on a distant part of the property, on which no work has been done. Men are placed at work on this and a shaft sunk 40 feet or more in the ore. By this time the mill machinery begins to arrive at the mine. The question of site has not been seriously considered, but a flat bench at the side of the gulch is selected, this being the only level bit of ground in the vicinity. True, it is up the gulch some distance above the mouth of the tunnel, but this is not material, as "the ore can be hoisted up an inclined tram into the mill cheaper than the cost of grading the hillside below the tunnel." All energies are now directed to mill construction, and at the end of ninety days the mill is completed under contract, and milling operations commenced. It is then discovered that the water supply is insufficient, but this can be developed further. In the meantime exploration in the tunnel has developed the fact that the vein has been crosscut diagonally and the vein is but 30 feet wide, instead of 100—bad, but it might be worse. In a few months the tailings outside the mill on the flat begin to give trouble. A bulkhead has to be built to prevent their running back into the mill. Soon the ore shoot begins to show signs of playing out at the ends. The foreman, working under directions, has a hard time to keep the mill supplied with ore. The new development in the shaft has not come up to expectations, and only one level is open on the main vein. After a struggling existence for a few weeks longer, the mill running on part time, the mine can no longer keep the mill going, and, hanging up one battery after another, the mill is finally shut down for several months, to await the development of the mine. During this period the general expenses are heavy and the outlook is unpromising. In time, the mill is again started up, and after several years of this sort of "seesaw" operation the property is either placed on a substantial basis, through the manager learning by experience at the expense of the stockholders, or it is closed altogether. How different all might have been had a competent engineer been engaged in the first place. Thousands of dollars would have been saved in equipment and thousands more in operation, but neither the stockholders nor the manager knew this. It may seem that the above is an exaggerated instance, but such is, in fact, not the case. It is, indeed, a very much better outcome of a bad situation than usually results under similar conditions, and is due largely to the fact that the mine is really better than the average and will stand considerable bad management and still pay a profit.

It is true that the technical mining engineer is not always a good business man, and failures are sometimes due to this lack of business experience, where success might have resulted, but in most instances the mining engineer has sufficient acumen to surround himself with a staff of specialists, as assistants, and among these will be found at least one who is competent to look after the commercial features of the concern. On the whole, as between the business man as a mining engineer, and the mining engineer as a business man, the proposition is largely in favor of the latter.

A New Interior Sea.

In the center of the Colorado desert, in southern California, an unusual spectacle may now be seen. For several months past the Colorado river has been running through a crevasse in its banks a few miles below Fort Yuma, the breach being caused by the digging of an irrigation canal from the adjacent country through the river bank, without providing it with the necessary head gates. This was done last spring during a comparatively low stage of the river, and at that time a considerable volume of water flowed from the river into the artificial irrigation ditch, known as the Imperial canal. With the coming of the summer floods due to the melting snows in the Rocky mountains, the breach widened and grew deeper until, it is stated, a large part of the Colorado river is pouring through the gap and that thus far all engineering efforts to check it and close the cut have proved unavailing. The water has flowed into an old channel known variously as New river and Hardey's, Colo., and has already covered the salt marshes and works at Salton, and has now commenced to submerge the tracks of the Southern Pacific Railroad. There are in this region nearly 4000 square miles of country below the level of the break in the bank of the river, and much of this is below the level of the sea. There seems a reasonable probability of this old lake, possibly at one time an arm of the Gulf of California, becoming a sheet of fresh water of considerable extent. It already covers many square miles of territory, and it is interesting to contemplate what may be the final outcome of this accidental formation of a new interior sea. It may have a noticeable effect upon the climatic conditions in that section, but it is scarcely likely that its influence will be felt beyond the mountains on the north and west of the basin.

THE annual report of the Calumet & Hecla Copper Mining Co., at Houghton, Mich., has recently been published for the year ending April 30, 1905. The statement of the company's assets and liabilities are undoubtedly satisfactory to stockholders, but the report deals with its operations and their cost in such a broad way that little knowledge of conditions other than those of a general character can be gained from reading the report. It shows an increase in production over the previous year, and the outlook for the future is stated to be promising. During the year four dividends were disbursed—three of $10 each and one of $15. It is also stated that by making changes in the old mills—modernizing them—that their capacity has been increased; but no details of stamping or mining operations and cost are given. This is in line with the policy pursued by this and some other great companies for many years, and it is to be regretted that such is the case, for much might be learned through comparison by mine managers everywhere if these important figures were available.

THE paper of T. H. Oxnam, appearing in the last Bulletin of the Transactions of the American Institute of Mining Engineers, on cyaniding of silver-gold ores at Palmarejo, Mexico, (the first installment of which appears elsewhere herein) cannot fail to be of interest to cyanide operators throughout the world. It has been known that silver was soluble in cyanide solutions, but practical application of this knowledge has been limited. In a few of the instances where the process has been tried, the difficulties have been so great that only moderately successful results have been obtained. In the instance above referred to, however, the author appears to have solved most of the problems and demonstrated the complete adaptation of the process to certain conditions.

IT has been officially announced that the inauguration of the Simplon railroad, which will unite Switzerland and Italy through the Simplon tunnel, the first of the two sections of which was recently completed, will take place October 10, 1905.

CONCENTRATES.

THE greenish appearance of some vitreous quartz from a gold vein is due to the inclusion of minute particles of chlorite.

✤✤✤✤

NUMEROUS ASSAYERS agree that there is a greater loss by cupellation in assaying telluride gold ores than with almost any other kind of ore.

✤✤✤✤

IT is stated that the rate of increase in temperature in some of the deep Victorian mines of Australia, down to 3000 feet depth, is 1° F. for every 75 feet.

✤✤✤✤

TWO nozzles are used on a water wheel of small diameter where high speed is required. The power of the wheel is thus doubled, though twice the amount of water is required.

✤✤✤✤

THE demand for pyritous ores for the manufacture of sulphur and sulphuric acid is increasing in the United States. In 1904 the sulphur and sulphur content of pyrite produced in the United States was 220,104 long tons.

✤✤✤✤

THE United States Geological Survey reports ("Mineral Resources, 1903," issued in 1904) that the commercial production of tungsten ores during 1903 amounted to 292 tons of 2000 pounds, valued at $43,639, or about $150 per ton.

✤✤✤✤

IT would be sufficient to simply drain the coarse concentrates before shipping, but it would be more economical to dry the finer concentrates in revolving cylinders or on drying floors. When fine ore is to be shipped, it is advisable to leave 2% or 3% of moisture, to prevent loss of dust.

✤✤✤✤

ZINC DUST is worth wholesale in New York City $0.05½@0.05¾ per pound. Zinc dust or fume is collected from dust chambers and stacks connected with zinc reduction furnaces, and consists chiefly of metallic zinc in the form of fine globules. It usually contains a small percentage of impurities.

✤✤✤✤

THE owner of an unpatented placer or quartz claim which is being properly held by compliance with the mining laws—Federal, State and local—is entitled to everything on the surface, in the way of timber, and vegetation of every description, as much so as though the claim were patented.

✤✤✤✤

THE business of quarrying marble has become closely associated with the installation of electrical plants throughout the United States. Marble is largely used as a mounting or backing for electrical switchboards, and marble quarries are required to supply a large amount of this kind of material.

✤✤✤✤

IRON is made from the various kinds and grades of iron ore by smelting in the blast furnace, by which it is converted into pig iron. Some of the processes are direct in their operation, and others require remelting and various other manipulations in the transformation from iron ore to wrought iron or steel.

✤✤✤✤

IMPACT wheels are not recommended for low heads—under 40 feet—except where a small amount of power is required. Sometimes more than one wheel is mounted on the same shaft. For heads exceeding 100 feet the impulse wheel is superior to any other. Turbines give the best results with large volume of water under low head.

✤✤✤✤

IT is said the copper deposits at Rio Tinto, Spain, were worked by the Romans over 2000 years ago, and by the Phœnicians centuries before them. The superficial ores were doubtless far richer than the sulphide ores worked to-day. These mines are on what are believed to be the most extensive copper deposits in the world.

✤✤✤✤

IN the manufacture of high grade self-hardening steels the elements employed to produce an extraordinary hardness is about as follows: Carbon, 0.40% to 2.19%; chromium, 0.00% to 6%; tungsten, 3.44% to 24%; silica, 0.21% to 3%. Molybdenum may be substituted for tungsten, when 1% of molybdenum replaces 2% of the tungsten.

✤✤✤✤

THE installation of a larger fan acting as an exhaust may improve the air circulation of a mine. Blowing fans are often inefficient, the development of the mine having outgrown the ventilating plant. A fan which will satisfactorily ventilate 5000 feet of mine workings may prove totally inefficient to supply air to twice this amount of development.

✤✤✤✤

THERE is not a very great difference between the Huntington-Heberlein process and the Carmichael-Bradford process. The former uses quicklime with the sulphide lead charge and the latter substitutes calcined gypsum. The process has been tried in an experimental way with raw copper sulphide concentrates at Anaconda, Mont., and is said to be a success.

✤✤✤✤

WHAT is known as the Frasch process of mining sulphur is in operation at the sulphur deposits in Louisiana, and consists in melting the sulphur in place in the deposit by means of hot water and then pumping the sulphur from a sump or well to the surface. This method of mining sulphur was invented by H. Frasch, president of the Union Sulphur Company of Louisiana.

✤✤✤✤

ROCK DRILLS may be heated by means of petroleum oil blast in a furnace of proper construction. Such a furnace offers many advantages over the coal or charcoal method. It is cleaner, usually less expensive, the temperature can be regulated to a nicety, and there is less steel burned in the oil furnace than in the ordinary forge. There is no loss of time in getting up heat and no ashes to be removed.

✤✤✤✤

COMPRESSED AIR as a means for driving mining pumps has many advantages over steam for the reason that it does away with the heat radiated from the pipe line, and from the pump itself, and the exhaust from the pump aids ventilation to a considerable extent, and under most conditions the loss of efficiency in the steam line, due to condensation, is greater than the loss of air pressure, due to cooling of the air current in the pipe line.

✤✤✤✤

MORE firebricks are usually used in the construction of a reverberatory furnace than are actually necessary. Some fuels make a much hotter fire than others. Petroleum with steam blast makes an extremely hot fire, and must be kept under control. It is not uncommon to see the bricks inside a furnace glazed from fusion due to the high heat. Such high temperatures are sometimes detrimental to the best results in roasting ore, converting iron, lead, copper, etc., into small metallic globules, which inclose minute particles of gold and silver, and unfit the ore for subsequent treatment.

✤✤✤✤

DOUBTLESS a signal code for the use of miners imprisoned underground could be devised. It is a well-known fact that sound travels a long distance through rock, and particularly through hard rock. The hammering on a rock wall can often be heard 200 feet or more. The strokes of a machine drill can frequently be heard 400 feet or more, and a sharp "click," which is characteristic of a distant blast, under favorable conditions can be heard more than 1200 feet. Miners frequently signal each other underground by hammering on the rocks, but, so far as known to "Concentrates," no code of such signals is in existence.

✤✤✤✤

UP to April 30, 1904, the United States Geological Survey had completed the topographic survey in California of 67,148 square miles out of a total of 158,360. In Colorado, at the same date, 35,101 square miles had been completed out of a total of 103,925. In Montana, 42,628 square miles had been completed out of a total of 146,080. In Idaho, 14,933 square miles had been completed out of a total of 84,800. In Nevada, 28,953 square miles had been completed out of 110,700. In Arizona, 60,813 were completed out of 113,020. The relative amount of area surveyed in the mining States ranged from one-third to one-half the total area of each State, Utah having nearly three-fourths, there being completed 62,628 out of 84,970 square miles.

✤✤✤✤

ACETYLENE GAS is a gas resulting from the addition of water to the chemical known as calcium carbide. The gas is a hydro-carbon (C_2H_2). It is used in lighting, to some extent in heating for culinary purposes, and more recently has been employed in gas engines. One pound of calcium carbide (worth in large lots about 7 cents per pound on the Pacific coast) with one-half pound of water, will evolve 5¾ cubic feet of acetylene gas. It is stated to have a heat capacity of over 18,000 B. T. U. per pound, or 1259 per cubic foot, at 14½ cubic feet per pound. About 12½ volumes of air are required to burn it. Acetylene lamps are very useful in mines, and the powerful light given by such lamps makes it possible to see the backs of high stopes, or to look some distance down shafts. It is superior for shaft inspection.

✤✤✤✤

THERE is much that is somewhat mysterious about the explosion of nitro-powders, gun cotton and other high-grade explosives, but it is agreed by all careful observers that when nitro-powder is surrounded by a medium such as air, water or rock, the explosive force is exerted equally in all directions, but manifests itself chiefly in the direction of the least resistance. That is, if a blast is fired in a drill hole the gases formed by the explosion, in their efforts to escape, will tear away a portion of the rock surrounding the drill hole. When dynamite is placed on top of a rock it will shatter the rock if it be not too large. If the same amount of powder is placed under the rock, and in contact with it, it will also shatter the rock, showing that the explosive force is exerted in an upward as well as in a downward direction. The impression that many have that the explosive force of nitro-glycerine and dynamite is downward only is erroneous.

✤✤✤✤

SILVER-LEAD ORES occur in many formations, but the most noted mining districts of the world where ores of this class occur are mostly in limestone formation, associated with porphyry intrusions, in the form of dikes and sheets. Some noted examples are Leadville and Aspen districts of Colorado, Eureka district of Nevada, Tombstone of Arizona, Little Cottonwood canyon of Utah, Santa Eulalia, Sierra Mojada, and a number of other districts of Mexico. Besides these, there are scores of other places of less note where silver-lead ores occur abundantly in limestone. A notable exception is the mines of the Cœur d'Alene district, Idaho, where the ores occur in quartzite. Silver-lead ores occur in schist, sandstone, granite, andesite and many other kinds of rock—sedimentary, metamorphic and eruptive—but its most frequent occurrence is in limestone. The lead-zinc mines of Missouri, Kansas, Arkansas, Iowa, Illinois and Wisconsin are wholly in limestone.

✤✤✤✤

SOME MONTHS AGO the experiment of treating cinnabar ores in White-Howell furnaces was tried at the Socrates quicksilver mine, Sonoma county, Cal. Two of these furnaces were installed. The larger of the two was 27 feet in length and 5 feet 8 inches in diameter, lined with fire brick. After several months trial it was decided that the furnace was not as well adapted to the work as the ordinary type of quicksilver reduction furnace. It was found that the ore was not exposed to the heat for a sufficiently long period to reduce all of the contained mercury. At the Socrates mine there is considerable metallic quicksilver in the ore, and this was readily vaporized and recovered in the usual manner, but the reduction of the cinnabar was found far from complete owing to the comparatively short exposure to the heat. When the furnace was set so as to give the necessary heat and time to effect complete reduction, the capacity of the furnace fell so low as to make the expense of the process prohibitive. The company is now building a large furnace of the Scott type, the rotary furnaces having been abandoned.

✤✤✤✤

THERE are a number of minerals which deposit a white coating on charcoal before the blowpipe. If the coating is deposited at some distance from the assay and is readily dissipated by directing the flame toward it, it is probably arsenic. If the white coating forms nearer the assay, it is more likely to be antimony. With antimony there is usually the formation of globules of metal which emit fumes for some time after the flame is removed, and, on further cooling, the metallic beads are surrounded by crystals of antimony oxide. If the coating on the coal is yellow while hot but white on cooling, the mineral is zinc. Tin also produces a yellow coating, but it is of a much lighter tint than that produced by zinc. The coating about tin is close to the assay, and it is not volatilized by the flame when once deposited. Lead gives a lemon-yellow color hot and a sulphur-yellow color cold, the coating quickly disappearing on application of the flame, which it colors blue. Bismuth gives a brilliant dark orange-yellow colored coating hot, fading to lemon-yellow on cooling. Cadmium gives an orange-brown color hot, changing to orange-yellow when cold. All charcoal used in blowpipe analysis should be tested without any mineral, to see that no color is produced by the blowpipe flame. Some kinds of coal are covered with a white coating and others by a brown color when cooled after ignition.

✤✤✤✤

WHERE there are no mechanical means for sampling ore in a mill, as suggested herein in a recent issue, the most reliable samples can be taken in a mine. If it is desired to supplement this with mill samples of headings, these samples should be taken from the chute leading from the bins to the feeder hoppers, this place offering the best opportunities for fair samples. They should be taken with a square shovel, and the shovel should reach the bottom of the stream of ore. The amount taken each time should not be less than 10 pounds (and more is better), and these should be taken at least hourly. This would mean twenty-four samples of 10 pounds each during each day—or 240 pounds of rock. This can be mixed and cut down on the cam floor and the surplus shoveled into the chute again. A 5-stamp battery ordinarily crushes from 12 to 25 tons per day of twenty-four hours, so that the entire sample only weighs from 1% to 0.5% of the amount passing through the battery. The "cutting down" can be quickly done with a shovel after mixing on canvas, by the quartering method. A small rock breaker and sample grinder combined are of great utility in carrying out this idea. The most important samples are those of the tailings. When the tailings are low, the bullion and concentrates should indicate the value of the ore if the millman is honest.

✤✤✤✤

WHERE a man owns a fraction—that is, a mining location less than the full length—and the neighboring land is unlocated, he may file an additional location certificate taking in enough additional land to make his location a full 1500-foot claim. Such additional certificates are usually provided for by statute, but the courts have held that this may be done even in States such as California, which have no statute on the point. It can not be done to the prejudice of existing rights of others. On the same principle is the case where the owner of the fraction owns another and contiguous fraction, each fraction alone being only 750 feet in length. As he might abandon one fraction, and then enlarge the other within the above rule, the law will permit him to accomplish this in a single step, on the principle that the law will not force a man to circuity of proceeding. He should select one of the fractional locations (preferably the older one) and file a certificate enlarging it so as to take in the other. This would operate as a relocation rather than as an amendment and can be done only if existing rights of others are not prejudiced. No change upon the ground is necessary if the name of the claim selected for enlargement is not changed, and the claim was originally perfectly regular; the old monuments already on the ground may be used. Thereafter annual labor would be required as for one claim only.

The Ancient Channel at Gibsonville, Cal.

Written for the MINING AND SCIENTIFIC PRESS by SAMUEL C. WIEL.

White cuts along hillsides are familiar in many of the mining counties of California, indicating generally ancient gravel deposits—usually deposits that have been hydraulicked. Famous among these is the deposit about Gibsonville and La Porte, in Sierra county. Work was begun there in the fifties. Such names as Poorman's Gulch, Poverty Flat and Whiskey Diggings are left to indicate the early scramble for locations. Each man worked for himself or with a few partners.

Company work on a systematic scale came much later, but to-day work has been entirely turned over to corporations. A few Chinamen still work the diggings for gold that nets them a day's wages. Survivors of the early days will tell you they are barely making a living, though they can remember when they took out $40 to $50 a day. The work on the gravel is being done now by corporations such as the Belleview, the New Bunker Hill, and others.

These gravels, around Gibsonville, are the remains of an old river, of Neocene time, now covered by lava. They crop out on the surface in all sorts of places, wherever erosion has removed the overlying rock (the lava cap) with which the ancient channels are usually covered. The miners call these exposures "blowouts," and "spills," as though some subterranean force had there squeezed the gravel to the surface. One old miner founded a theory of the entire phenomena of ancient gravels on this idea. He told the writer that these buried gravels never were the beds of streams, but were ordinary rocks broken up at great depths and squeezed through to the surface, the rounding of the gravel being due to a wearing away in the process. The exposures in a general way are not found on the hilltops, but in the canyons or gulches, or on the sides of gulches, where erosion has been greatest and has removed more of the lava than elsewhere.

Having found a "blowout," in the early days, it was hydraulicked. The gravels paid well that way; but legislation has since made this method of mining almost prohibitive. At Gibsonville one hydraulic mine is at work still, but at the expense of three impounding dams. These log dams, expensive at the start, are now almost filled up, necessitating the expense of raising them. There is considerable low-grade gravel left in the ancient Gibsonville channel, especially on the rims, where tributaries probably entered; but the possibility of working these profitably has been legislated away.

The channel between La Porte and Gibsonville is covered with andesitic breccia of the later Tertiary. The river deposit under this lava has been penetrated at the Thistle shaft, about 4 miles southeast of La Porte. Work on this shaft was difficult because of a considerable inflow of water. To avoid this difficulty in the shaft, a long bedrock tunnel known as the Belleview has recently been completed by the same company. It is said that their perseverance has been rewarded by striking a wide pay channel running $3 a car. The Yankee Hill gravel, near Slate creek, on the road from La Porte to St. Louis is perhaps a part of the La Porte channel, but there remains some doubt about it. From Gibsonville the gravel may be followed continuously through Whiskey Diggings to Hepisdam, formerly prosperous camps, but now in decay, where the channel disappears under the lava. From La Porte to Gibsonville the average present grade of the bed of the Neocene river is about 80 feet to the mile; from Gibsonville to Whiskey Diggings, about 250 feet to the mile; and from the latter place to Hepisdam, a distance of over a mile, about 400 feet to the mile. These measurements, while not accurate, have a comparative value. "As the character of the gravel and of the old channel does not appear to have changed in this distance, the rapid increase in grade is in all probability to be ascribed to subsequent differential elevation toward the east," says Turner.

By hydraulicking and washing along a stretch 2 miles long in a southwesterly and northeasterly line, the continuity of the gravels has been proved. For that length a strip, sometimes a thousand feet wide, has been exposed, washed clear of the lava covering, and down to bedrock. At the northeasterly end of this line the lava cap was early found too thick for hydraulicking and about a mile from Gibsonville the Hepisdam drift mine was started, tunneling under the lava. This mine, now known as the North America, is said to have taken out between $800,000 and $1,000,000. The gravel maintained the same character as that in the works below. They had the misfortune of running out of bedrock with their tunnel, into the gravel and above it, rendering their tunnel finally too high to handle the gravel, a frequent cause of misfortune in drift mining. It was the custom of this mine to raise from their bedrock tunnel into the gravel and take out all the gravel indiscriminately, to a height of about 4 feet above bedrock, and yet the gravel taken thus would run between $1.50 and $2 a car.

The line of the ancient channel appears now continuously for about 2 miles on the surface. The covering being washed away, it looks from the hills like a fairly straight white line of quartz gravel and boulders, disappearing under the lava at the North America dump. From here on it can be traced in the same (northeasterly) direction by the air shafts of that mine, beyond the summit of the ridge of lava that covers it. On the other (eastern) side of this ridge lies the New Bunker Hill drift mine, where the gravel is similar in character. From there on, beyond the Bunker Hill, the continuity of the channel is doubtful. Deep canyons come in, whose erosion probably cut out the ancient channel. There are, however, two masses of white quartz gravel at the north and west base of Blue Nose at the edge of the lava, about 500 feet below the Bunker Hill tunnel, which may be downthrown portions of the Hepisdam river deposit. That extensive faulting has occurred

Looking for Nuggets in the Sluice of a Placer Mine, Sierra County, Cal.

Cleaning Up the Sluices of the Bunker Hill Mine, Sierra County, Cal.

about Blue Nose is evident. That the region about Blue Nose was formerly one of volcanic activity, where the lavas issued, is also apparent according to Turner, though there is no evidence of faulting in the Bunker Hill tunnels.

Much of the lava about Blue Nose is massive andesite, in part dikes, occupying fissures in the bedrock. A little over a mile northeast of Mount Fillmore is some gravel under the andesite, and both andesite and gravel are cut by basalt dikes.

The New Bunker Hill, while undoubtedly on the same ancient channel system as the North America, is probably on a tributary and not on the main channel. They have met a series of benches running, not in the direction of the Gibsonville channel, but across it; and it is hoped, by following in the direction of these benches, to demonstrate conclusively that the Gibsonville channel crosses their ground. The New Bunker Hill, like the rest of the drift mines in this neighborhood, was started by following a "blowout" which was found at the head of Hopkins creek. Work here is being done more carefully now than in the old days. Instead of breasting out broadly over the bedrock, a prospect dump is used. Carloads of gravel are separately washed and only the pay streak is followed.

All the ancient gravels contain free gold. Pieces worth over $50 are not frequent; but pieces worth $20, or so, are frequently found and are called "slugs." In washing, the slugs are usually found in the upper 20 feet of the flume. At the Bunker Hill, the flume extends far down the creek, mercury being used in the lowest flume to catch the smaller particles, but not in the upper flumes. The tailings contain practically nothing, and even the Chinamen do not undertake to wash the tailings.

The character of the gravel in this ancient channel is interesting. The gravel deposit is very wide, in some places reaching 1000 feet—very different from the mountain streams found there to-day; it would seem more comparable to lower streams like the Sacramento river. At one time it was a popular theory that the ancient gravels throughout the Sierra region were a part of a single great river, but a closer geological study has caused this idea to be discarded, and it has been shown that there were numerous ancient rivers, independent of each other. There are so many of these large ancient channels in California, moreover, that it is unlikely that they bear any relation whatever to any single stream of the present day. So large were these streams that one would expect the deposit to be fine grained and the gravel regular and small; but, on the contrary, the gravel is as irregular as in narrow mountain torrents of the present day. The deposit varies from clay and fine sand to boulders the size of a house. At the Bunker Hill these huge boulders on bedrock often give trouble in mining. The gold will sometimes lie on one side of them, as though they had some favorable influence in causing its deposit; but they give difficulty in handling material.

From these huge boulders the gravel grades down in size. It is very irregular in shape, and decidedly angular. It is not as rounded as one would expect of material coming from a distance, and this indicates that the formation of this channel must have been comparatively rapid, or that the part at present exposed is not far from its source. The larger boulders are almost invariably white quartz; yet no quartz veins have been found from which such huge pieces could have come; probably they have long since been eroded away. The conditions suggest the possibility of ice having been a factor in the creation of this channel.

No evidence of faulting or disturbance has been found in the Bunker Hill, though on other channels the gravel has been lost through faulting, or has been cut off by dikes and igneous intrusions of various kinds. In the North America, on this channel, a fault is said to have been met with, which caused the channel to drop below the level of the bedrock tunnel of that mine, and rendered its tunnel useless. The Bunker Hill tunnel was driven at a lower level, to allow for this fault, as the Bunker Hill is directly up stream from the North America. The quartz boulders frequently break up and splinter when blasted, which may be due to the pressure of consolidation under the weight of overlying material.

For ventilation, air shafts are raised to the surface at intervals along the tunnel. These shafts cut layers of gravel, sand and pipe clay; the upper layers of gravel containing much less gold than the lower or bedrock gravel; and only the bedrock gravel is worked. Water is conveyed by ditch to these air shafts, and, in falling through them, produces a strong current of air for ventilation. The bedrock is usually the Mariposa slate of the Jurassic period—a bluish black, soft material, that sometimes swells on exposure to air, and occasionally makes heavy timbering necessary.

Tantalite for Incandescent Lamps.

Recently Dr. Feuerbach delivered a lecture before the joint session of the technical and electrotechnical associations of Frankfort, Germany, in which he said, in part, that endeavors have constantly been made to construct lamps of greater light-giving efficiency, for the present efficiency is only 1%, 99% of the energy used being converted into heat. As it was known that the light-giving efficiency increases with the increase of the temperature, it was the general desire to use for threads in the lamps metals which have a very high melting point, instead of carbon threads. The tantalite incandescent lamp is the result of years of experiment. Tantalite occurs in nature in various minerals. There are two groups of tantalite ores—tantalite and columbite. The tantalite ores, which are found in Australia and Scandinavia, contain tantalate of iron and tantalate of manganese. The columbite ores contain, in addition to tantalite, niobate of iron and of manganese, and were first found in New England. From these ores tantalite is first separated as tantalitic acid, which is converted into a double fluoride of tantalite and potassium, from which tantalite is finally derived as a pure element.

Tantalite as a metal was first found by the Englishman Hatchet in 1801. As the real discoverer of this element, however, must be named Eckeberg, who made investigations in 1802. Berzelius was enabled, in 1824, to free tantalite of its associated element,

but even he did not succeed in obtaining pure tantalite.

Dr. von Bolton first succeeded in obtaining pure tantalite. Tantalite is a heavy mineral with a gray metallic luster, extremely resistant to acids and alkalies. Only fluoric acid affects it. Its specific weight is 16.8. Pure tantalite has the hardness of soft steel, but possesses a much greater tensile strength. It can be worked into thin sheets and extremely fine wires. Its melting point lies between 2250° to 2300° Celsius. Through repeated annealing it acquires such hardness that tantalite sheets withstand even a diamond borer.

The technical use of large quantities of tantalite is at present impracticable, as one pound of this element still costs nearly $5000. Of what importance the chemical and physical properties of tantalite are for the industries is shown by the fact that Siemens & Halske, for the various processes of manufacture and use of tantalite, have taken out more than 200 patents in Germany and other countries. The incandescent lamp with a tantalite instead of a carbon thread has various advantages over other means of lighting. The tantalite lamp requires only one-half the current of ordinary incandescent lamps of equal light power. With the same strength of current the tantalite lamps give double the light of the carbon incandescent lamp, and the light is much whiter. The lamp is pear-shaped, like the ordinary incandescent lamp, and the thread has a length of 650 millimeters (25.59 inches) and is 0.5 millimeter (0.197 inch) in diameter. The lamp can be placed in any position. The medium life of a tantalite lamp is from four to a hundred light hours.

Splicing Transmission Rope.

Rope transmission is an important factor in the operation of many mines. Ropes are employed in the transmission of power in mills and about mines, and a more extended use of this economical means of handling power and distributing it to desired points is certain to follow a more thorough understanding of the methods of application and its advantages. One of the important features in rope transmission is the splicing of the ropes. This must be properly done or the operation of the plant cannot be satisfactory. The splicing of a transmission rope is not a difficult matter when understood. As a matter of course, by frequent repetitions of the operation the workman becomes more expert and the result of the improvement, which is the outcome of experience, is observable in the more enduring quality of the splices. The C. W. Hunt Co., of 45 Broadway, New York City, have recently issued a catalogue, No. 054, entitled "Manila Rope," which contains much valuable information on rope transmission and on ropes and their use generally. Incorporated in this handsome little volume are a number of cuts, which show clearly the methods of splicing. The following description and illustrations are published through courtesy of the C. W. Hunt Co.:

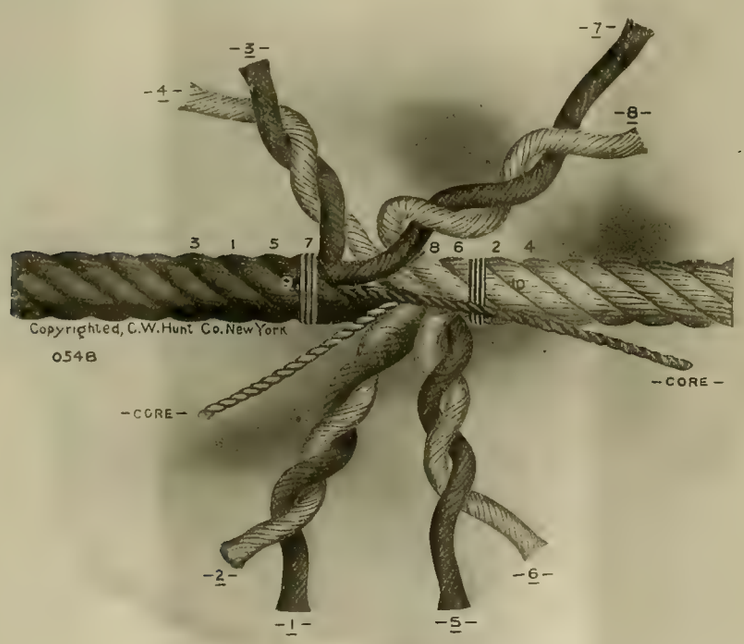

Fig. 1.

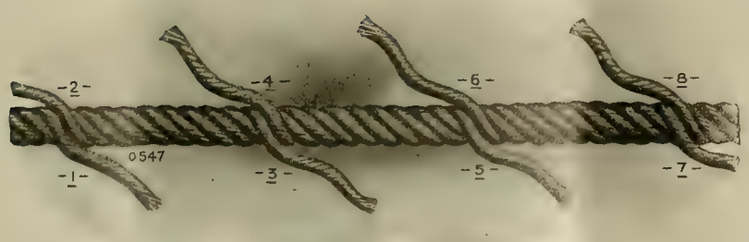

Fig. 2.

SPLICING.—To properly splice a rope or tie a knot that will not slip is a simple operation, and it would be supposed that almost any workman would be able to do either, but the difficulty of getting the splices put in a rope in manufacturing establishments has been a serious drawback in introducing the use of rope for the transmission of power. There is but little information on splicing a transmission rope in technical literature, and as ordinary rope splices are not suitable for this purpose, the following description and cuts will serve a useful purpose.

Fig. 3.

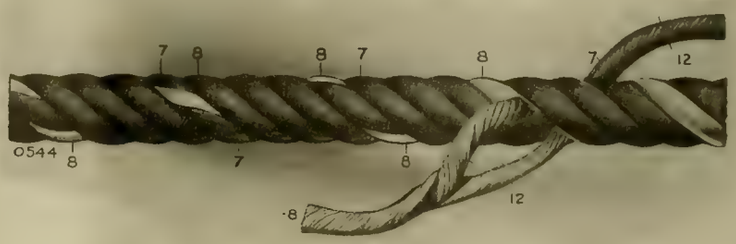

Fig. 4.

The splice in a transmission rope is not only the weakest part, but is the first to fail when the rope is worn out. If the splice is not long enough the rope will fail by breakage or pulling out of the splice. If the splice is improperly made it will be larger than the rope and the projecting parts will wear on the pulleys and the rope fail from the cutting off of the outer threads of the strands.

If it is desired to profit by the experience of others, do not put in a "short splice" or an ordinary "long splice," or get an "old sailor" to do the work, but have a handy man follow implicitly the directions given below for a splice in a four-strand transmission rope.

We have had accurate engravings made of each successive operation in splicing a 1¼-inch manila rope, and also of the most common knots. Each engraving was made from a full-size specimen, and accurately shows the position of the parts.

Tie a piece of twine, 9 and 10, around the rope to be spliced about 6 feet from each end. Then unlay the strands of each end back to the twine.

Butt the ropes together and twist each corresponding pair of strands loosely, to keep them from being tangled, as shown in engraving, Fig. 1.

The twine 10 is now cut, and the strand 8 unlaid, and strand 7 carefully laid in its place for a distance of 4½ feet from the junction.

The strand 6 is next unlaid about 1½ feet, and strand 5 laid in its place.

The ends of the cores are now cut off so they just meet.

Unlay strand 1, 4½ feet, laying strand 2 in its place.

Unlay strand 3, 1½ feet, laying in strand 4.

Cut all the strands off to a length of about 20 inches, for convenience in manipulation.

The rope now assumes the form shown in Fig. 2, with the meeting points of the strands 3 feet apart.

Each pair of strands is successively subjected to the following operation:

From the point of meeting of the strands 8 and 7, unlay each one three turns; split both the strand 8 and the strand 7 in halves as far back as they are now unlaid, and the end of each half strand "whipped" with a small piece of twine.

The half of the strand 7 is now laid in three turns, and the half of 8 also laid in three turns. The half strands now meet and are tied in a simple knot, 11 (Fig. 3), making the rope at this point its original size.

The rope is opened with a marlin spike, and the half strand of 7 worked around the half strand of 8 by passing the end of the half strand 7 through the rope, as shown in the engraving, drawn taut, and again worked around this half strand until it reaches

the half strand 13 that was not laid in. The half strand 13 is now split, and the half strand 7 drawn through the opening thus made, and then tucked under the two adjacent strands, as shown in Fig. 4. The other half of the strand 8 is now wound around the other half strand 7 in the same manner. After each pair of strands have been treated in this manner, the ends are cut off at 12, leaving them about 4 inches long. After a few days' wear they will draw into the body of the rope or wear off, so that the locality of the splice can scarcely be detected.

The Ore Deposits of Mount Lyell.*

NUMBER III.

Written by J. W. GREGORY.

It is, of course, obvious that the Iron Blow was not formed by the simple alteration of the pyrites by surface waters and air; for in that case the iron would have been present as a hydrous oxide of iron, such as limonite, instead of as hematite. Apparently limonite only occurred where the hematite had been acted upon by surface waters. It is accordingly most natural to regard the Iron Blow as some type of lode, formed under conditions which have led to the deposition of red hematite from iron solutions. The iron was probably leached from pyrites in the underlying rocks, and was precipitated along the fault lines, where the ascending waters, containing iron salts, met other solutions which had worked their way downward through the conglomerates. The position of the Iron Blow beside the pyritic mass is only natural, for the conditions which favored the ascent of the solutions which deposited the pyrites, also enabled the ascent of the other. The anhydrous hematite was naturally also deposited where the conglomerates have been faulted down against the schists; for the surface waters could pass through the porous conglomerates, and thus mix at some depth with the ferruginous waters and precipitate their contents.

F. D. Power has suggested that the Iron Blow is a segregation lode, thereby showing that he fully recognized that it was not formed by the mere decomposition of the pyrites. The striking difference between the ores of the Iron Blow and the pyritic masses is the poverty of the ironstone in copper and silver. These metals may have been once present in it; but they, being more easily removed as soluble sulphates, have been entirely leached out and carried down. The rich shoots of silver-copper ore found at the southern end of the pyritic mass of Mount Lyell probably derived their contents from the leaching of the Iron Blow. These bonanzas or enrichments are secondary enrichments, formed by water working its way downward through the ores and leaching out the more soluble salts; the metals in these salts were deposited again lower down, along the drainage lines in shoots, which thinned out below, as they got further from the source of supply.

The iron gossan of the Iron Blow was, therefore, probably formed from pyrites by the conversion of the iron sulphide into ferrous sulphate and of the enclosed copper and silver into cupric and silver sulphates. As a solution of ferrous sulphate is a solvent for gold, that metal also was removed at the same time. The solution then percolated into the schist of the hanging wall side, where further chemical changes took place. The ferrous sulphate was decomposed and the iron precipitated as ferric oxide (Fe_2O_3); the gold was immediately precipitated. The sulphate of barium, which had also been introduced at the same time, was precipitated along with the iron and gold, forming the barytic hematite of the Iron Blow. The copper and silver were perhaps precipitated in the hematite, and, being more soluble, have been subsequently removed by leaching processes, and then concentrated on the margin of the hematite. It appears, however, to be more probable that the copper-silver ores were deposited at the same time as the hematite, but at a slightly lower level, owing to their greater solubility. This conclusion is supported by the fact that the hematite shows little evidence of subsequent percolation. Had water passed through it, the oxide would, in all probability, have been altered into limonite.

Peters estimated, after the most exhaustive and careful process of sampling, that the Mount Lyell ore would yield an assay value of copper 4½%, silver 3 ounces and gold 2½ dwts. He estimated the width as 300 feet; the length actually traced at that time was 950 feet. Limiting the payable ore to a width of 200 feet, thus excluding the low-grade ores on the hanging wall, and taking the weight of the ores as 280 pounds per cubic foot, he calculated that there would be 9,200,000 tons; deducting half that amount for contingencies, he estimated there were 4,600,000 tons of ore above the workings existing at that date, and above the level of the tunnel which it was then proposed to carry through the ridge to the smelting works at Queenstown. Actual work has, however, proved that the average of the ore used up to the end of September, 1902, was considerably poorer; 1,320,134 tons had then been smelted, which yielded an average assay value of copper 2.92%, silver 2.74 ounces and gold .097 ounce (that is 1.94 dwts.)

THE SOUTH LYELL MINE.—The South Lyell mine is in a lease situated due south of the Mount Lyell mine, and in this lease a considerable body of low-grade pyritic ore has been found. A shaft was sunk at a point in line with the Iron Blow of the Mount Lyell mine, in expectation of reaching the continuation of the Mount Lyell "lode." The mouth of the shaft is at the level of 1368 feet above the sea; it reached pyrites at 844 feet above sea level, and continued through it to 720 feet above sea level, or 648 feet below the mouth of the shaft. This mass of pyrites, with an apparent thickness in the shaft of 124 feet, has been proved by subsequent work to be a large pyritic body, 140 feet long and 70 feet wide, running from north 50° west to south 50° east. It must be cut off abruptly above, as, if it had continued upward at the same dip as in the shaft, it should have been passed through by a diamond drill bore made from the No. 5 to the No. 6 level of the Mount Lyell Co. The absence of any extension from the South Lyell ore body in that bore shows that it ends abruptly above, just as the pyritic body of Mount Lyell ends abruptly below. The ore of the two mines is remarkably similar in character. Their distance from one another is approximately that of the throw of the great thrust plane which has brought the conglomerates between the schists in the Mount Lyell mine. Hence the evidence renders it probable that we have to seek for the subterranean source of the Mount Lyell ores through the South Lyell ore mass. The ores of the South Lyell mine on the footwall, just above the schist, are enriched with fahlore, due probably to the leaching from the ores along the hanging wall, and the deposition of the material on the lower side of the deposit. The South Lyell ore mass contains one large intrusion of schist. The average ore contains .5% to .6% of copper, and has been mined for use as fuel in the smelting of the acid ores from the North Lyell mine.

The mass of ore could be most economically worked by driving from the Mount Lyell mine. The ore is cut through by a fault, which left the pyrites polished like a mirror; a specimen of the slickensided pyrites from this fault is preserved in the Hobart museum.

THE NORTH LYELL MINE.—I was unfortunately unable on either of my visits to Mount Lyell to examine the underground workings of either the North Lyell or Lyell Blocks mines. An inspection, however, of the surface workings and subsequent information, kindly given to me by W. T. Batchelor, shows that both mines are associated with extensive faults.

The North Lyell mine is situated at the extreme head of the Linda valley, beside some bold crags of conglomerate, which rise on the ridge which forms the divide between the Linda and Queen valleys. The mine occurs close by the contact between the schists and conglomerates, the junction of which is complicated by an elaborate series of faults. The ore has been worked by a deep open cut, the bottom of which is 1647 feet above sea level. The contact of the schist and conglomerate is part of the Great Lyell fault, which has a general trend from north to south; but opposite the main ore body a cross fault breaks across the Great fault, throwing the southern part to the northwest. This face of the cross fault is well shown in the open cut, where the ore has been removed from the north of it, leaving exposed a bumpy, wavy surface of conglomerate.

The ground included in the lease of the North Lyell Co. is probably more faulted and disturbed than any other equal area in the Lyell field. The mine includes at least five distinct ore beds, four of which are enclosed in schist and occur in the bays or angles between the Great Lyell fault and the transverse faults. The so-called eastern ore body, on the other hand, occurs to the east of the Great fault, and its ore is different in character and position from that in the ore bodies along the main fault. The eastern ore is a siliceous pyritic material carrying copper; it contains much organic matter, and has conglomerates on its northern side. The main ore body and those associated with it occur enclosed in schists. They are disconnected shoots of ore, formed of bornite, in siliceous schists. The largest body is known as the main ore body, and was once thought to have been part of the second largest body, which has been almost worked out by an open cut.

THE GENESIS OF THE ORES.—The determination of the genesis of the Mount Lyell ores is necessary both in estimation of the future history of the field and in the determination of the most economic method of working it. Upon the first discovery of the Iron Blow and its adjacent pyrites they were regarded as ordinary mineral lodes. The strike of the main deposit having been determined, it was, therefore, natural to expect that other deposits of copper ore should occur along the continuation of the Mount Lyell line. Great encouragement was given to this view by the discovery of the fahlbands, which certainly extend in long bands through the schists, and also by the wide distribution of alluvial gold in the field, which, it was rightly inferred, was mainly derived from the decomposition of auriferous copper-bearing pyrites. Though the only payable gold deposits were those found on the slopes below the Mount Lyell mine, enough was found elsewhere to support the hope of the wide distribution of the copper ores. The land, both north and south of the mine, was, therefore, taken up by companies and searched for the continuation of the Mount Lyell lode.

Thus the South Lyell Co. acquired a lease immediately to the south of the Mount Lyell mine, and sank a shaft at a point selected solely because it was on the extension of the longer axis of the Mount Lyell ore body.

Most of the early literature of the field and of the prospectuses that were issued by the various mining companies expressed the belief that the field was traversed by parallel series of copper-bearing lodes. Thus the prospectuses of the South Mount Lyell Co. stated that a large proportion of the Mount Lyell lode was already proved within its boundary, and it was also proved that the whole ore body is directly entering it. The Mount Lyell Blocks Co. claimed that its lode is in all probability the same as that which traverses the North Mount Lyell. The Great Southern Mount Lyell Mining Syndicate claimed for its 300 acres "that three distinct lodes, as well as in all probability the Great Mount Lyell lode, occur across its northeastern corner." The prospectus of the Copper Mines of Mount Lyell West Co. claimed that its Kelly shaft and Razorback lode would be found to be the continuation of the North Consolidated and Extended main lode.

It was accordingly a great blow to the founders of the so-called "parasite companies" when Peters announced his famous swamp formation theory. Peters held that the pyrites had been formed by the reduction of copper sulphate solutions by the action of the organic agents in a swamp. The theory was probably suggested by the well-known deposit of iron ore at the Mesa de los Pinos, near Rio Tinto, which has unquestionably been formed by the reduction of ferrous sulphate solutions derived from the pyrites of the Rio Tinto mine. This method of origin is certainly theoretically possible. Peters' theory of the formation of the Mount Lyell ores is as follows:

"These deposits are believed by those who have studied them most carefully to have been formed before the period of mountain building began in this country, and when the layers of schist that are now nearly vertical were in the same horizontal position in which they were originally laid down, these schists, or neighboring rocks, containing particles of iron pyrites carrying the valuable metals, as is exceedingly common with all varieties of sedimentary rocks. The waters flowing through the gradually decayed and dissolved pyrites, as one can see it to-day in most any district, and the streams flowing into some lagoon or bog hole, came in contact with the peaty, organic acids that are always found in the waters of swamps, and that have the peculiarity of throwing down the metals out of their solutions. These metals were thus precipitated in the same state that they were originally in the rock, but in a massive, concentrated form, instead of being disseminated in minute particles throughout the rocks. In time the slowly growing mass of pyrites filled the swamp hole, or, more probably, a chain of holes, of great horizontal extent in comparison with their depth. The country was slowly covered with the pebbles that now form the conglomerates, or the mud that we now see in the shape of slates or schists, and the pyrite beds were buried hundreds of feet under these newer rocks. When the mountains were elevated these layers of rocks were tilted into their present highly sloping position, and if the upturned edges happened to break across one of these hidden deposits of pyrites, it was brought to the light of day."

From this hypothesis it follows that such swamp deposits might occur at irregular intervals through the sedimentary series, and need not be confined along great fissure lines due to subsequent earth movements. Other similar masses of pyrites might occur wherever the swamp conditions had been repeated during the formation of the sedimentary rock series of the district. Peters, by a hypothetical section across the country, illustrated his conclusions that the swamp deposits would be irregularly distributed, and the only chance of finding them would be where they actually outcropped at the surface. If his hypothesis had been established it might have been possible to define the limits within which these pyritic lenses would be found. For they would occur only in the bands of rock which enclose the swamp deposits. Therefore, by tracking the outcrop of the bands of fresh water strata the possible limits of the copper ores would be directly determined.

Peters' theory, though it was adopted by many writers on the Lyell field—for example, Montgomery and McNamara Russell—has not been confirmed by subsequent work. Further ore deposits have been found, but all those of any importance occur in association with a series of powerful faults and near the junction of the conglomerates and the schists. Hence arose the contact theory, which during recent years has been generally held upon the field.

Contact ore deposits are generally regarded as those which have been formed by the contact of igneous rocks against some different rock, such as, for example, the lead ore deposits of Leadville, Colo., due to the contact of beds of porphyry against beds of limestone. Thus Kemp, in his "Ore Deposits of the United States and Canada" (1900, p. 58), in his classification of ore deposits gives as the essential feature of contact deposits that "igneous rocks always form one wall," and on page 69 says that "this form of deposit becomes then an attendant

*Abstract Trans. Aus. Ins. Min. Engrs.

phenomenon, or even a variety of contact metamorphism."

In this strict sense the Mount Lyell ores cannot be regarded as contact deposits, as they are not due to contact with intrusive igneous rocks. But if the term contact be used in a much wider sense, then it is not without some justification, for the great pyritic masses appear to be indirectly due to the fracturing of the schists, where they have been crushed against the harder masses of conglomerate.

The first point that must be determined is the source of the ores; and here it is natural first to turn to the fahlbands, so widely scattered through the schist series. They were regarded, both by Peters and Haber, as of primary origin, whereas Haber regarded the pyritic masses on the other hand as secondary. This view was a natural corollary to the prevalent theory of the formation of ore deposits by lateral secretion; for, according to Peters, the ores in the great pyritic masses were obtained by the leaching of the disseminated pyrites from the decomposing rocks beside his swamps. Haber expressly states that "the fahlbands are to be regarded in any case as primary ore formations. On the other hand, the nature of the pyritic ore bodies indicates for them a secondary origin." Microscopic evidence, however, clearly shows that the pyritic minerals in the schists are as truly secondary as they are in the pyritic mass.

In the second place, the minerals present in the ore masses have very sharply defined crystallographic outlines, and are often built up as loose skeleton crystals, showing that they have crystallized in situ after the foliation of the schists. It may be suggested that the ores were formed by organic deposition and then were recrystallized, and that this recrystallization has destroyed the evidence of their original nature. Even then we should expect a much greater variation in the composition of the ore near the margin of the pyritic mass. Montgomery logically inferred from the swamp theory that the ore mass would increase in size below, as the uniformity of the material showed that the ore then exposed was not near the margin of the pyritic mass. He reasonably expected that there would be alternations of pyrites and mechanical sediments on the margin, due to the gradual increase in the deposition of the pyrites, and later on to its decrease.

A third and more conclusive argument against the primary nature of the pyrites is the clear evidence in parts of the mine that the pyrites have been formed metasomatically by the replacement, molecule by molecule, of the original rock by pyrites.

The swamp theory is untenable when it is admitted that the rocks in which the pyrites occur are not a continuous sequence, and that the schists and rocks beside the great ore masses have been faulted together. The pyritic masses have been deposited not only later than the deposition of the rocks, but also later than the formation of the chief faults.

That the ores in the fahlbands and pyritic masses are of approximately the same origin was suggested by Peters owing to their similar composition. It is well, therefore, to compare the composition of these two types of ores. The assay value of the ore at the Mount Lyell mine may be divided into three distinct types, the low-grade pyrites that pays to work only as a fuel, the payable pyrites, and the stoping ores. Their metallic contents are as follows:

	LOW GRADE ORES.		PAYABLE
	Between Levels 4 and 5.	Below Level 5.	ORES.
Copper, %.....	.64	.57	2.92
Silver, ozs. per ton.....	2.15	1.74	2 74
Gold, oz. per ton.....	.048	.04	097
	STOPING ORES.		
Copper, %.....		10.94	4 55
Silver, ozs. per ton.....		6.23	3.58
Gold, oz. per ton.....		.022	.119

The composition of the fahlband ores may be illustrated by the analysis of unusually rich ore from the Lower Reserve tunnel, and of the metal-bearing flux of the Royal Tharsis:

LOWER RESERVE ORE.		ROYAL THARSIS FLUX.	
Copper, %.....	6.96	Copper, %.....	1.68
Silver, oz. per ton.....	.36	Silver, oz. per ton.....	.24
Gold, oz. per ton.....	.008	Gold, oz. per ton.....	.026

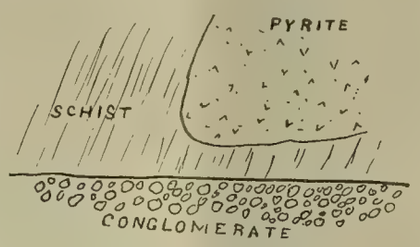
The relative ratios of copper, gold and silver in the metal-bearing fluxes and in the pyritic ores of the Mount Lyell mine have been recalculated in the company's laboratory, and Mr. Sticht tells me that Mount Lyell ores are much richer in gold and silver than the mineral in the fahlbands. This appears to me natural, if the pyritic masses have been formed by secondary concentration.

Whether the ores were formed after the rocks in which they occur (that is, are epactic, to use the term of Louis), or were formed later (the symphytic of the same author, or the hysteromorphs of Posepny), may be conclusively determined by considering their relations to the faults. It is perfectly certain that the faults of the district are later than the formation either of the schists or conglomerates. If, therefore, the ores were formed later than the faults, then they cannot have been contemporaneous with the surrounding rocks. The ore deposits at the South Tharsis mine, the North Lyell mine, and the Mount Lyell mine are all certainly in part later than the faults.

The most striking geological feature of the Mount Lyell mineral field is its great fault system, and an examination of the distribution of the ores shows that they are in every case closely connected with the faults. These faults were not all made by the same earth movement; they were no doubt formed at different dates, extending over a considerable period of time. The deposition of the ores was probably going on simultaneously with the development of this complex fault system. Hence in one place the ores have been earlier than the faults and elsewhere they are later.

Many minor faults traverse the Mount Lyell ore body, and some of them disturb the general uniformity of its composition. Two faults were conspicuous on the floor of the open cut in January, 1903. One of them and another on the hanging wall side of the ore body were filled with black carbonaceous clay, formed as a fault rock. Some of this type of material contains some native copper and is rich in silver. An interesting chimney of enriched ore near the southeastern corner of the open cut also owed its origin to fault action, for faults ran close beside it, in places separating the 9% ore of the enrichment from the 1% ore outside. The rich ore passed a little beyond the faults, as if the enrichment had taken place along the faults and worked from them in both directions.

These faults traverse only the pyrites. Those on the floor of the open cut were unquestionably later than the formation of the ore. The faults beside the enrichment, on the other hand, were probably earlier than at least the completion of the ore body. In the lowest level of the mine there are some interesting sections, which show that the superposition of the schists on the conglomerate occurs along lines of faulting, and that the foliation of the schists is cut across transversely by the conglomerates, as shown



Unconformability at Mount Lyell Mine.

in the accompanying sketch. They are, therefore, younger, not only than the formation of the schists, but are also younger than the date at which the schists were foliated.

Methods and Costs of Placer Mining in Alaska.

Placer mining in Alaska is affected by conditions which are not combined in any other field familiar to American miners. Many an old placer miner of California has come to grief in the Northern clime because he was unacquainted with the peculiar conditions that exist there. During the last three years the United States Geological Survey has received numerous requests for information regarding the cost of operating gold-bearing alluvial deposits in Alaska and the best means of working the claims in the various districts. To collect data for a report which should embody such information, the Geological Survey sent C. W. Purington, a mining engineer of Denver, Colo., to Alaska during the field season of 1904. Accompanied by Sidney Paige, Mr. Purington visited the Juneau, Atlin, Klondike, Birch Creek, Fairbanks and Seward Peninsula districts, stopping on the return trip at the gold-dredging field of Oroville, Cal. The results of Mr. Purington's investigations are now available in the form of a Survey bulletin (No. 263) which is entitled, "Methods and Costs of Gravel and Placer Mining in Alaska." This work includes data concerning districts not visited by Mr. Purington or his assistant, notably the Porcupine, Christochina, Cook Inlet, Forty-mile and Rampart districts, and remote parts of the Seward Peninsula; but all such information has been collected from reliable sources, especially from members of the Geological Survey who have made investigations in those portions of Alaska.

In each district a study was made of the water resources—the most important factor in placer and hydraulic mining—and of the cost of building and maintaining ditches, flumes and storage reservoirs for the purpose of using water under pressure. The important development of ditch building in the Seward Peninsula receives particular attention in the report.

The quantity and quality of timber in the mining districts is discussed by Mr. Purington with reference to its use for fuel, for the construction of flumes and sluice boxes and for timbering drift mines. It is an unwelcome fact that the important placer districts of the Northwest do not contain a great amount of timber.

The questions of wages and cost of living have been considered from both the viewpoint of the laborer and his employer. While the rate of pay for miners appears attractively high, the cost of living and the expenses of transportation to and from the country have to be considered, as well as the shortness of the active season and the low rate of winter wages.

The main objects of this report have been to determine the most expeditious way of getting out the auriferous material—gravel, sand or bedrock—and the cost of so doing; the best methods of hydraulic mining; the cost of removing overburden under each set of conditions and of handling the tailings; the capacity and cost of installing mechanical methods; the cost, capacity and adaptability of the methods employed to thaw frozen gravel, and the most feasible method of mining in little-developed districts.

While many of the figures presented in this bulletin are subject to fluctuation, yet, as a comparative study of mining methods, Mr. Purington's report will be a valuable and permanent contribution to mining literature. It is published for general distribution and may be obtained free of charge on application to the Director of the United States Geological Survey, Washington, D. C.

The Machine Drill in Mining.

NUMBER III.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS.

Within the past two years a new and important factor has been introduced into the mining field in the form of a small machine drill, which at first sight seems like a toy, as compared with even the smaller of the ordinary type of machine drills, with which we are familiar. Some years ago a so-called pneumatic hammer was introduced into the machine shops of the country. This tool was used as a chipping, and then as a calking hammer, and later came to be extensively employed as a riveting tool. It was then modified to be employed as an instrument for cutting and dressing stone. From these uses it was but a step to converting the pneumatic hammer into a rock drill. Its particular field of usefulness was in block-holing and in cutting hitches on rock walls, or in drilling shallow holes for squaring up rock work. From these useful functions the drill has been applied on still broader lines and it is now being employed as a rock drill on regular work, in shafts, tunnel work, stopes and everywhere that rock drills are used. Just what will be the eventual outcome of this new type of drill it is almost too early to undertake to predict, but the indications are that it has come to stay. There are several of these small drills on the market already, and others may be anticipated. At first the drill was small and was intended to be used in the same manner as the riveting hammer, being held in the hand of the operator, but that its usefulness for general work would be limited in this form soon became evident, and the drill was enlarged somewhat, mounted on a bar, either horizontal or vertical, and in this form is adaptable to any class of mining work. A new attachment of one of these drills is that of a device which keeps the bit up to the rock by direct air pressure. The steel used is generally hollow and the exhaust passes down the hollow drill steel and blows the drillings away as fast as made by the cutting bit. In some types water is forced through the hollow steel, which washes away the drillings while preventing all dust. In others a spray is arranged to dampen the drillings as they come from the mouth of the drill hole, thus settling the dust. These small drills weigh but sixteen to eighteen pounds, and the air consumption per minute is said to be small—less than 20 cubic feet of free air per minute, at a pressure of 80 to 100 pounds per square inch. It strikes over 2000 blows per minute, and under favorable conditions will drill from 100 to 150 feet per shift of holes, of a maximum length of 3 feet, cutting a hole about 1 inch in diameter. It is said that holes can be drilled with ease much deeper than 3 feet, but this is approximately the limit of rapid operation, in the present stage of development of this interesting type of machine.

Although this small pneumatic-hammer drill has attracted much attention of late, and has been introduced in mines and is now being tried under all sorts of conditions, it is not likely that it will for a long time, if ever, displace the larger type of machine drills which have for years been so successfully operated in all parts of the world. The efficiency and adaptability of the old type of machine drill is well understood, and miners, as a class, do not look with favor upon radical innovations, though they are susceptible to the process of evolution, and can be readily led by stages to favorably consider and adopt a type of machine with which they are at first wholly unacquainted. The advantages of the pneumatic-hammer drill lie chiefly in its easy portability and light weight, and this will no doubt quickly make it popular for certain classes of mining and quarry work, where the handling of large machines is more or less difficult. It has few working parts; is easily kept in order, and has many good points in its favor, but it will, notwithstanding this, have to earn its way and overcome the prejudice of miners against making radical changes of any kind in their methods of work.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

Written by T. H. OXNAM.

INTRODUCTION.—The predominating value of the ores now being treated by the Palmarejo & Mexican Gold Fields, Ltd., is silver, although some gold is also carried.

The present method of treatment consists of wet crushing and concentrating, followed by the cyanidation of the unroasted sands and slimes. The sands are treated by leaching and the so-called accumulated slimes by a system of agitation and decantation.

It is only within very recent years that the cyanidation of unroasted silver ores has been commercially successful. In fact, at the time operations were begun at the cyanide plant at Chinipas, February, 1902, I knew of no other leaching plant treating similar ores successfully. The cyanide treatment of the Palmarejo ores differs but little from the ordinary practice in cyaniding gold ores, and perhaps but little, if any, new information concerning the metallurgy of silver is to be gleaned from it.

PALMAREJO MINE. — The Palmarejo mines are located in the southwestern part of the State of Chihuahua, Mexico, on the foothills of the Sierra Madre mountains, at an elevation of 3200 feet. The mills, 12 miles distant, are situated on the Chinipas river, near the town of Chinipas, which is about 150 miles northeast of Agiabampo, on the Gulf of California. Supplies are shipped via this port, as this route is the best and most direct to the property.

The ore bodies in the Palmarejo mines have been deposited along a series of rock fractures, caused by an intrusion of eruptive rock. The most important of these fractures or fissures, both in width and value, are the Prieta and Blanca veins, which intersect each other on the surface at a point called the Descubridora, or discovery, and underground in the main working tunnel (Socorro) about 800 feet from its entrance. (See Fig. 1.)

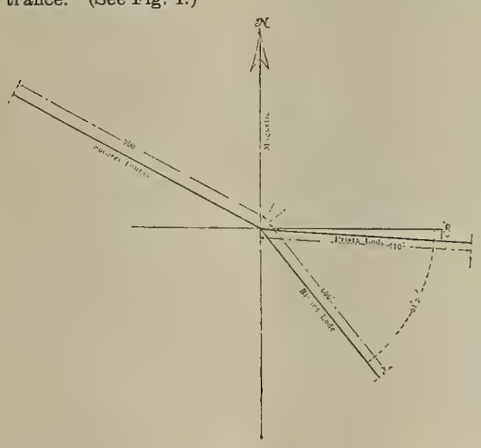

Fig. 1.

From the junction of the two veins the Prieta strikes almost due east and the Blanca south, 51° 30′ east, dipping at an angle of 50° to the west.

The Prieta vein in places is fully 75 feet wide between walls. The ore, however, is frequently in two sections, known as the foot wall and hanging wall sections of the vein, with a horse of country rock from 10 to 30 feet thick between them.

Stoping has been done on both the foot wall and the hanging wall sections on the course or strike of the vein for 2000 feet in length, and, while the values are continuous, the better grade of ore makes in chimneys or shoots varying from 75 feet to 300 feet in length.

The Blanca vein, which varies from 4 feet to 12 feet in width, has been mined for a distance of 850 feet. At the junction of the veins the bonanza of the mine was found, which has been worked for more than 800 feet in depth and has yielded an enormous amount of money.

The records in the office of the company show that these mines have been worked for more than a century.

The ore delivered to the mill consists essentially of a siliceous matrix, throughout which is disseminated a small percentage of pyrite. Black manganese oxide and calcite are present in varying proportions, and very small quantities of antimony and arsenic, together with traces of bismuth, also occur. Occasionally traces of copper and zinc are found.

The major portion of the silver occurs in the form of argentite, though a certain amount of stephanite is present and occasionally small patches of chlorobromide and native silver.

The main storage bin of the Palmarejo group of mines is connected with the mill by means of a narrow gauge railroad 12.5 miles long. The mill is about 1300 feet lower than this ore bin, consequently the entire road is on a moderately heavy grade—the heaviest slightly exceeding 4.5%. The gauge of the road is 30 inches; two weights of rails are employed, one being 35-pound and the other 25-pound per yard. Two English locomotives are in service; one a 22-ton engine hauling fourteen cars and the other an 18-ton engine hauling nine cars. Each ore car has a carrying capacity of 4.5 tons. Under normal conditions, from 4 to 4.5 hours are required for making a round trip.

MILL AND CYANIDE PLANT.—The 50-stamp mill and cyanide plant is situated on the edge of the Chinipas river, about 1.5 mile eastward of Chinipas, at a place known locally as El Zapote. Water power furnished by the Chinipas river is used to run the mill, slime plant and machine shop. A masonry conduit about 11 miles long conducts the water to a penstock a short distance above the mill, thence through a steel pipe about 1100 feet long, tapering from 48 inches in diameter at the penstock to 24 inches in diameter in the wheel pits, to four 6-foot Pelton wheels under a 97.5-foot head.

OLD SYSTEM OF MILLING.—The mill was originally erected as a dry crushing, roasting and pan amalgamation plant and was operated as such until the middle of October, 1901. On my first visit to this property, December, 1900, the mill operations and methods of ore treatment were substantially as follows:

The ore was drawn from the main storage bin at the top of the mill over iron grizzlies to the five 7x10-inch Blake crushers, running 250 revolutions per minute. From the large storage bin beneath the crushers the ore, after the addition of 5% by weight each of salt and sulphurets, was conveyed to three White–Howell cylindrical driers, each 18 feet long and ordinarily rotated at six revolutions per minute, the speed given them, however, naturally depending upon the percentage of moisture contained in the ore passing through them at the time. Two driers easily handled the quantity of ore crushed by the stamps, even in the rainy season.

Each drier discharged into a small storage bin, from which the ore was conveyed in half-ton cars to the hoppers of ten Challenge ore feeders. The stamps when equipped with new shoes weighed 850 pounds and dropped from 4 to 7 inches, according to the condition of the shoes and dies, at a speed of from 85 to 90 drops per minute. Both the shoes and dies were cast on the premises, in the foundry of the company. Mortars were of the wide, double-discharge pattern, and 20-mesh brass-wire screens were used. The stamp duty was from 1.25 to 1.5 ton per twenty-four hours.

The dry pulp, discharged through the battery screens, was carried by means of a series of belt conveyors and elevators to three revolving cylindrical roasters of the White–Howell type, lined with firebrick made in the vicinity. These roasters were 27 feet long, 2 feet 9 inches inside diameter at the feed and 3 feet 6 inches inside diameter at the discharge, and were rotated at an average speed of three revolutions per minute. The roasted ore was wheeled in cars to a large brick storage pit, where it was allowed to remain for from eighteen to thirty-six hours, after which it was drawn out on the cooling floor and sprinkled down with a hose.

Daily tests made on average samples of the roasted product, taken as it left the roasters, showed that about 80% of the silver was rendered soluble in sodium hyposulphite. When cooled sufficiently to handle, the roasted material was shoveled or raked into cars and trammed into twenty amalgamating pans of the McCone pattern, each 5 feet in diameter. The usual charge consisted of 2800 pounds of ore, 150 pounds of quicksilver, 15 pounds of salt and 1.7 pound of bluestone. The quicksilver, salt and bluestone were added as soon as a pan was charged. The pans were run at an average speed of sixty-eight revolutions per minute and were kept at a temperature of from 100° to 110° F. by means of steam added through a small pipe directly to the material being treated. After from six to eight hours' treatment, the pans were discharged into 8-foot settlers, each two pans being provided with one settler. From the settlers the tailings were discharged into 10-foot agitators, one agitator receiving the discharge from two settlers. These agitators, however, for some time previously had not been used as agitators proper and were serving merely as mercury traps. The tailings escaping from the agitators were carried by the water race to the Chinipas river.

While the process of treatment outlined above has given very satisfactory results with many ores of similar nature to the Palmarejo ores, though perhaps in districts more favorably situated for freighting facilities, it had never proved to be a commercial success on the ores of this company, due chiefly to the unusually high working expenses. Owing to the isolated position of this property, freighting expenses were a very heavy item, as, in addition to steamer or railroad transportation to the nearest seaport, practically all of the freight had to be transported by wagon for a distance of 110 miles, of which the last 60 miles into the property is by way of rugged mountain trails, permitting only mule-back transportation. It can thus be readily seen that the freighting cost alone proved a very considerable item. Due largely to this reason, combined with the fact that the quantity treated was comparatively low, the expenses of maintenance and repairs per ton treated were very high.

A considerable percentage of the ore passing through the roasters was carried into the dust chambers and flues, a portion of which escaped and was entirely lost. The material caught in the flues and dust chambers was periodically removed and treated in the pans without further roasting. This semi-roasted flue dust was given a longer and special treatment, but the extraction obtained from it was always considerably lower than that obtained on the well-roasted material.

Another very serious source of loss was in the volatilization of a considerable portion of the silver content during the roasting. During the year ending June 30, 1901, more than 22,000 tons of ore were crushed in the mill, comprising 20,000 tons of ore and 1000 tons each of salt and sulphurets. Five per cent of the weight of the ore was lost as moisture in passing through the driers and an additional 6% by weight was lost between the batteries and the pans, such percentage being due almost entirely to losses by volatilization and dusting while passing through the roasters. The assay results for this year showed that approximately 12% of the total silver content contained in the ore was lost by volatilization during roasting. The total working cost for this period was $24.20 per ton, divided approximately as follows: Mining, $8.12; milling, $14.32; ditch, 60 cents; railway, $1.16; total, $24.20. The average assay for the year of the ore as delivered to the mill was 30 ounces of silver. The average of the ore as charged into the pans was 25.4 ounces of silver. It was always considered practically useless to send to the mill ore which carried less than 30 ounces of silver per ton. The average extraction of silver for the year as indicated by bullion returns was approximately 77% of the value of the material panned, this being equivalent to 66% of the total silver value of the ore crushed Ordinarily the ore was not assayed for gold and no special attention was given to effect its recovery. While a part of the gold was caught and saved in the pans, it is more than probable that the major portion contained in the ore was entirely lost.

The Production of Pyrite.

"The demand for pyrite has increased very largely throughout the United States and many European countries during the last few years," says Dr. Joseph Hyde Pratt of the United States Geological Survey in a recent report on the production of sulphur and pyrite in 1904. It is used in the wood pulp industry as well as in the manufacture of fertilizers. Owing to the steady increase in the demand, it is not improbable that prices will gradually advance for the best qualities of ore.

The chief domestic sources of supply of pyrite are deposits in Virginia, California and Massachusetts. Smaller amounts are obtained from Alabama, Georgia, Indiana, New Jersey and Ohio. The deposits in these States do not supply the demand for pyrite, and a considerably greater quantity is usually imported each year than is produced in this country. The chief sources of supply of the imported pyrite are the celebrated Rio Tinto and Tharsis mines of the Huelva district in Spain, the San Domingo mine at Pomaron, Portugal, and the Tilt Cove mines of Pilley's Island, Newfoundland.

The pyrite industry in Spain has now reached a point where the shipping facilities are inadequate to handle the product. In order to increase the shipping facilities at the port of Huelva and to expedite the loading of steamers, the Spanish Government is erecting a new dock at that port. Although these Spanish deposits are enormous and new bodies of ore have been uncovered during the last year or two, there is still such a large and steady drain upon them that some of the European countries are beginning to look elsewhere for supplies of pyrite. On account of the rapid increase in the manufacture of fertilizer in Spain, Italy and France, these countries are making large demands upon the Spanish pyrite for use in the preparation of sulphuric acid.

New deposits of pyrite in Alabama have recently become available through the completion of the Eastern Railroad of Alabama from Talladega to Pyriton. For this material there should be a large demand at Nashville, Tenn., as a source of raw material for its fertilizer factories. These Nashville factories are already advantageously located with reference to the Tennessee phosphate fields, so that, with easy access to the Alabama pyrite deposits secured, they should be able to compete readily with any other fertilizer plant.

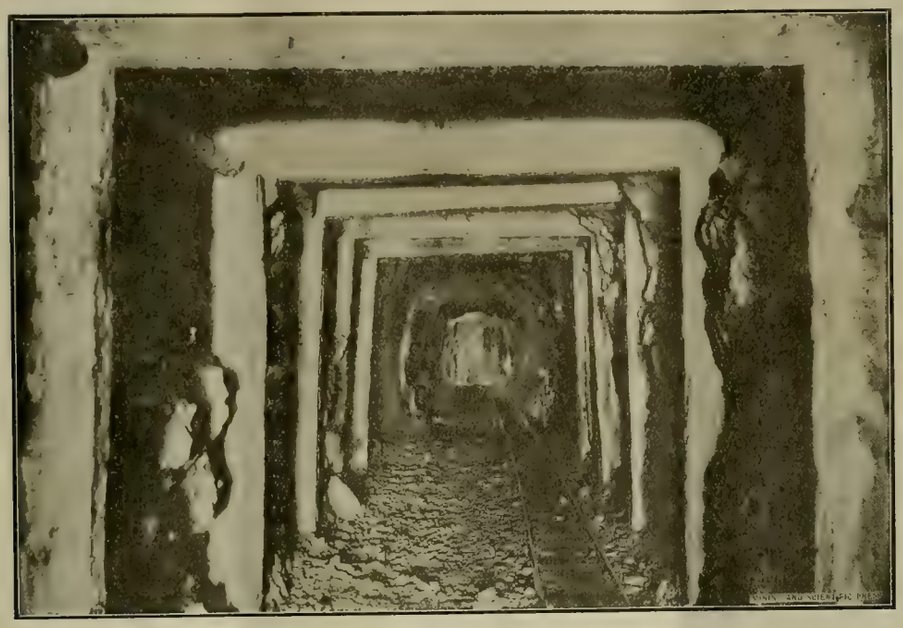
The anxiety felt in European countries regarding a source of supply of pyrite should stimulate prospecting for pyrite deposits in this country. It would be well to know accurately what are the future sources of supply of this mineral in the United States, in case the foreign sources of supply should begin to give out or there should be too heavy a demand made upon them by European consumers.

There was a slight decrease in the production of pyrite for the manufacture of sulphuric acid in the

United States during 1904, but a very large increase in the production of natural sulphur, the combined production amounting to 333,542 long tons, valued at $3,460,863, as compared with 233,127 long tons, valued at $1,109,818, the production of 1903, an increase of 100,415 tons in quantity and of $2,351,045 in value. This exceptionally large increase in value as compared with the increase in tonnage is due to the very large increase in the production of sulphur. A considerable quantity of pyrite is also mined for pyritic and allied smelting and for use as a flux, which would increase the output by 75,000 to 100,000 tons. Over one-half of the total production of pyrite was obtained from Virginia. The average price received for the 1904 production was $3.86 a ton, an increase of 24 cents as compared with $3 62, the average price received for the 1903 production.

Tunnel Construction.

In tunnel construction there is a great diversity of methods, both in breaking the rock and in timbering the ground after the excavation has been made. In some tunnels the character of the rock passed through requires close and heavy timbering, with lagging top and sides. In other cases the timbers may safely be spaced 5 feet from center to center and lagging employed only overhead, as in the case here illustrated. Often the roof only requires support, the walls standing without lagging. Where the excavation has been made in a flat, sedimentary formation, caps have sometimes been inserted after the manner of stulls and tightly wedged, the lagging being driven overhead to support any loose ground that may occur. The method is not in common use, however, and in only a few places can it be rendered secure.



Drainage Tunnel, East Argentine District, Colo.

In soft and swelling ground, the practice is to spread the legs of each set abnormally so that they stand at an angle of 40° to 45° with the horizon. This has a tendency to keep them in position and aids somewhat in resisting the crushing force of the slowly moving ground, but usually this expedient only affords temporary relief and the timbers have frequently to be renewed, or the ground cut away to ease the pressure on the timbers. In many tunnels, after getting beyond the zone of weathered rock, no timbers are required, the rock being sufficiently hard to stand without timbers. In other instances rock which at first stands well, after a time, begins to disintegrate and numerous falls of the back occur. When these are of frequent occurrence, it is usually cheaper to timber all of that portion of the tunnel in which these falls occur, for, having commenced, they are more than likely to recur with increasing frequency, and become a constant menace to life, as well as an annoyance and source of expense. The tunnel here illustrated was originally intended for a double track, though but one line has been placed in position.

Tunneling requires often nearly as much engineering skill and the exercise of as good judgment as shaft sinking. If care is used there is no reason for a tunnel getting out of alignment, though it is a very common thing to see careless work done, the heading swinging from side to side and eventually running at random, first following one rock seam and then another, in the effort to follow easy ground. In one instance it was figured that at least 10% of the cost of mining was saved by following seams "to break to," but the tunnel was driven not less than one-fifth farther than necessary to reach a given point, so as a matter of fact it was really more expensive, and required a greater length of time to reach this point than if the tunnel had been driven perfectly straight.

Ore Deposits of the Cœur d'Alene, Idaho.

NUMBER IV—CONCLUDED.

Written by F. L. Ransome.

Treatment of the Ores.—The Hercules mine ships only crude ore. The Bunker Hill & Sullivan, Last Chance and Hecla mines ship a little crude or picked ore, which in no case exceeds 2% of the total tonnage mined, or 7% of the total shipping product. The greater part of all the ore mined is concentrated in the district to a product containing from 50% to 60% of lead. The number of tons of ore reduced to one ton of concentrates varies. Of the low-grade Gold Hunter ore about twelve tons are required to make a ton of concentrates containing 50% of lead and 55 to 60 ounces of silver. In the Bunker Hill & Sullivan mill 7½ tons of ore, containing from 8% to 16% of lead and from 3.6 to 6.8 ounces of silver to the ton, are concentrated to one ton containing about 55% of lead and 19.5 ounces of silver. From 900 to 1000 tons of ore are treated daily in this mill and about the same quantity in the Morning mill. The combined Standard and Mammoth mills treat from 1000 to 1200 tons daily. The saving effected in the best mills is about 80% of the total market value of the lead and silver.

The ore and concentrates from the Bunker Hill & Sullivan mine go to the Tacoma smelter, owned by the company, where they are smelted with concentrates from the Treadwell mine, on Douglas island. The Hercules ore also goes westward, to the Selby Smelting & Refining Co. in California. The concentrates from the Hecla are shipped to the Ohio & Colorado Smelting & Refining Co. at Salida, Colo. Most of the ore from the other mines goes to the various plants of the American Smelting & Refining Co., particularly to the smelter at East Helena, Mont., although considerable quantities are sent to Denver, Pueblo, Omaha and El Paso.

Cost of Mining and Treatment.—The cost of mining and concentrating per ton of ore stoped ranges from about $2 in the Wardner mines to about $3 in the Canyon Creek mines, where the ore bodies are narrower and where pumping and hoisting are necessary. In the Bunker Hill & Sullivan mine the costs per ton of ore stoped in 1903–4 were as follows:

COSTS IN BUNKER HILL & SULLIVAN MINES.

Mining and concentrating	$1 97
Freight and smelter charges	2 17
Discounts for loss of lead and silver in smelting	60
Total	$4 74

The average assay value of this ore was $6.80 per ton. The freight on ores and concentrates varies from $8 to $12 a ton, according to tenor, and a uniform charge of $8 a ton is made for smelting. Ore of which more than twelve tons is required to make one ton of concentrates containing 50% of lead can rarely be made profitable.

The Gold Deposits.—The only gold-bearing veins that are now productive occur near Murray. The quartz veins on Elk creek apparently produced some gold several years ago, but the workings upon them have long been abandoned and are not accessible. The best known veins near Murray are the Golden Chest, just north of Littlefield, and the Mother Lode group of veins on Ophir mountain, situated on the south side of Prichard creek, between Littlefield and Murray.

With few exceptions the veins of the Murray area belong to the class known as bed veins (Lagergange). They usually follow the stratification planes of the Prichard formation. Occasionally they jump from one plane to another, the two parts of the vein being connected by small stringers across the intervening bed. In the Golden Chest mine there are at least six of these bed veins in a zone 150 feet in width. Their general strike is about north 17° east, and they dip westward at angles ranging from 40° to 45°. These veins are usually a foot or two in width, but in some places a width of 10 feet is attained. They are filled with quartz, often strikingly banded, containing free gold, auriferous pyrite, galena, sphalerite and chalcopyrite, with occasional bunches of scheelite. The best ore is said to have been worth $70 to $90 a ton and was shipped crude. The ore now worked in the 20-stamp mill is of much lower grade, probably not over $7 per ton.

On the north face of Ophir mountain are two bed veins, one 250 to 300 feet vertically above the other. These veins have a general northeast strike, and dip northwest at angles of 18° to 20°. The veins are of the same general character as those of the Golden Chest mine, but contain rather less abundant sulphides. These were formerly worked by the Mother Lode, Occident and Treasure Box mines by flat stopes extending from the surface into the hill. Some pockets of rich ore, containing much free gold, have been found in these mines and were treated in arrastras. The veins as a whole, however, are of rather low grade and have not been stoped for more than a few hundred feet from the surface. Their average width is probably not over 8 inches. Just west of these veins is the Mead vein which strikes about north 15° east and dips easterly at about 75°. This is a fissure vein, cutting the beds of the Prichard formation. Its relation to the bed veins east of it is unknown, as it apparently has not been considered worth while to explore the intersections or junctions of these veins. The Mead vein is said to contain a pay shoot of $25 ore. The vein consists of white quartz with sometimes a little siderite (or other ferruginous carbonate) near the walls and with auriferous pyrite, chalcopyrite and galena in the medial portion. A number of small bed veins have been worked west of Murray, the most noted being the nearly horizontal Buckeye Boy in Dream gulch, which produced about $25,000 in gold from a single small pocket.

Placers.—The older placer deposits of Murray constitute what is locally called the Old Wash and are remnants of an earlier channel of Prichard creek from 250 to 300 feet above the present stream. These gravels, which are in part derived from older gravels deposited still higher above the present valleys, have been hydraulicked near Murray, but have not proved very rich.

Most of the placer gold of the Murray region has come from the bottoms of the existing gulches and has been obtained by simple sluicing, booming, drifting and dredging. The bed of Prichard creek has been worked about a mile west of Murray by a hydraulic elevator, but the depth of the gravel, which averages about 30 feet, has proved in most cases an insurmountable obstacle to successful exploitation. In 1903 three dredgers were at work near Delta, of which one only, at the mouth of Trail creek, was operated at a profit, on gravel running about 10 cents to the yard.

The gravel of Trail creek, near Delta, is from 18 to 20 feet deep, and was formerly worked by sinking shafts to bedrock and then drifting. In this method the water is impounded in a reservoir fitted with an automatic discharge gate. When the reservoir is full the gate opens, and the whole body of water is directed against the gravel in such a manner as to wash it away. A small stream is thus rendered far more effective than if it were continuously employed. When the gravel has been removed to within 2 feet of the bedrock the remainder is shoveled into sluices.

The gold is coarse, nuggets up to 40 ounces having been reported. They are usually somewhat hackly, and often contain particles of quartz. From $15 to $18 an ounce is usually obtained for the placer gold.

The Copper Deposits.—The only productive copper deposit in the region is that of the Snowstorm mine, east of Mullan. The deposit occurs in the Revett quartzite, and consists of an impregnated cupriferous zone, which conforms with the bedding planes. The deposit strikes north 60° west, and dips 65° to the southwest. It has a maximum width of 40 feet. The ore consists of chalcopyrite, bornite, chalcocite, and perhaps other cupriferous sulphides disseminated in small particles through the quartzite and in part oxidized to cuprite and malachite.

The mineralization along the zone is not easily accounted for, as the quartzite is not particularly fissured and is apparently not different in character from the quartzite of the foot wall and hanging wall.

The greater part of the mineralized quartzite contains about 4% of copper, 6 ounces of silver, and 0.1 of an ounce of gold to the ton. The ore shipped is worth from $9 to $10 a ton, and goes to Butte and Tacoma. Smelting and freight charges are $5 a ton,

but the smelters require that the silica shall not fall below 90%. In 1903 a leaching mill was being erected on the South Fork to treat the ore.

GENERAL CONDITIONS OF MINING.—The turbulent condition that existed in the Cœur d'Alene district from 1892 to 1899, and the notoriety given the locality by the deeds of violence then perpetrated, justify a brief account of the present relations of the mine owners to their employes.

Up to 1892 all men working in the mines received $3.50 a day. In the spring of that year the depression in the prices of lead and silver called for retrenchment in operating expenses, and wages were reduced to $3, except for miners, who retained the old rate. The results of this action have already been related. The men struck, but finally returned to work on the mine owners' terms. Shortly after, on the ground that further economy was necessary, wages were reduced to $2.50 a day. The men again struck, and the mines, after a period of idleness, resumed operations with wages at the original rate of $3.50 a day. For the next few years the miners' unions were dominant, and the mines were operated under their rule. The attempt of the Bunker Hill & Sullivan mine to free itself from these restrictions brought about the crisis of 1899, which put an end to the rule of the unions.

At the present time all the prominent companies, with one exception, engage their men through a central employment bureau. The wages paid in the principal mines are as follows:

WAGES PAID IN PRINCIPAL MINES IN CŒUR D'ALENE DISTRICT, IDAHO.

Foreman	$6 00 to $7 00
Locomotive engineers (Morning mine)	6 00
Shift bosses	4 00 to 6 00
Head blacksmiths	4 50
Hoisting engineers	4 00
Blacksmiths	4 00
Timbermen	3 75 to 4 00
Miners, machine men, muckers, millmen and blacksmiths' helpers	3 50
Yard men	3 00

These wages, all things considered, are undeniably good, for the district is readily accessible, has a moderate altitude, and an almost ideal climate. The mines, moreover, have convenient adits and are well equipped and well ventilated. The cost of living, compared with other mining districts in the Rocky mountains, is moderate.

The present conditions in the district appear to be satisfactory to employers and employes. Wages are as high as they were before trouble began, but lawlessness no longer exists, property is secure, and mines can be operated without improper interference. As a result the district enjoys a prosperity which was impossible under former conditions and which is shared by all who are developing its resources.

Power.—The district is well supplied with water, very little of which is allowed to run to waste. The Bunker Hill & Sullivan, Morning, Hunter, Hecla Mammoth and Standard mills are all run by water power for at least part of the year, usually by Pelton wheels under heads up to 900 feet. Water power is also utilized to a considerable extent for compressing air, the Morning mine having a 100-drill Rix compressor driven by Pelton wheels under heads of 1200 to 1500 feet. The Hecla mill and the pumps in the Tiger–Poorman mine are usually run by electricity, locally generated by water power.

Recently electric power, generated at the falls of Spokane, has been brought into the district and is used in running the Tiger–Poorman and Last Chance mills, a 40-drill compressor at the Morning mine, and other machinery. The length of the line from Burke or Mullan to Spokane is about 100 miles. In 1903 this line was carrying 45,000 volts and furnishing 1600 H. P. The cost of this power at the mines is $50 per annum for each horse power. This is cheaper than steam, though the latter power is used at the Tiger–Poorman and Standard–Mammoth mines.

Timber.—All of the large mines require much timbering, and probably few mining regions are better supplied than the Cœur d'Alene district with abundant and cheap material suitable for this purpose. A large part of the timber used is derived from the vicinity of Cœur d'Alene lake. Some is cut in the southeastern corner of the district, and the Hercules mine has its own timber land and sawmill on the north side of Tiger peak.

Engineering in the Wilderness.*

The development of mines in new regions, remote from civilization and from convenient means of transportation, often calls for no little engineering skill on the part of the superintendent and his staff. Roads have to be built through swamps and over mountains; ditches, flumes and pipe lines must be constructed over a rugged country, and it is not always advisable to take the longest way around, as this means usually excessive cost. It is here that engineering knowledge becomes useful. Possessing it, the superintendent is able to judge as to the relative cost of each—the long way around or the short cut, which latter calls for unusual methods of construction and a class of expense not met on the longer route. The accompanying engraving illustrates the point. Here it was necessary to build a pipe line to carry water from one point to another. It was partly through a dense forest of pines. Ditch construction was feasible, but expensive, owing to the character of the country and the necessity of blasting out stumps and roots, a work both slow and expensive. An estimate of the cost of a pipe line was made, and it compared favorably with the ditch proposition, consequently the pipe line was decided upon. The trees felled along the line supplied more than enough material for the construction of a suitable trestle, and on this the pipe line was laid. Less in first cost than a ditch which would deliver the water to the desired point, it requires less expense to maintain, and is a good example of engineering under natural difficulties in Alaska. This construction was built to supply the Sea Level mine with water and power. The pipe line is 4400 feet in length, the pipe being from 22 to 24 inches in diameter.

*See illustration front page.

Government Experiments With Black Sand.

Written for the MINING AND SCIENTIFIC PRESS by WALDON FAWCETT.

The tests and experiments now being made by officials of the United States Geological Survey in an effort to devise means to save all the mineral wealth in the black sands of the Pacific coast come as the culmination of considerable research and investigation, giving attention for the first time to the commercial status of the situation. They are naturally, therefore, of exceptional interest to all mining men. The tests are being conducted at a special concentrating pavilion of the Lewis and Clark Exposition at Portland, Or., which was chosen as a central point and one which, by reason of the fair, will be visited this year by many mining men who are interested in the outcome of these experiments and in the methods employed.

As the result of invitations sent out to mining men, the Government officials have received numerous shipments of sand from Washington, Oregon, California, Idaho, Utah and other States. Samples are also expected from Alaska, where this same class of material is found. All experiments are being made under the direct supervision of Dr. David T. Day of the United States Geological Survey. He states that it is as yet too early to predict regarding results, but that it has already been demonstrated that the methods employed are the correct ones.

At the concentrating pavilion the sand first enters a feeder, from which it is elevated by a belt elevator and delivered to a screen. Thence it passes to a vertical revolving mixing distributer from which it is piped to the four different concentrators, this method insuring an even character of pulp to all machines. A drying furnace constructed in accordance with ordinary modern practice is provided for drying the concentrates as they come from the various concentrators. After the pulp has been dried it is passed through a magnetic separator where the magnetic elements are extracted. After passage through the magnetic separator the material is examined for the platinum and other rare minerals, the securance of which is the especial object of the governmental activities.

Four concentrating tables are in use. All are electrically operated. The Wilfley concentrator is operated by a 2 H. P. Westinghouse motor. Woodbury's concentrating table derives its motive power from a motor of the Crocker–Wheeler type, 1½ H. P. and 500 volts. The Pinder concentrator is operated by a Wagner–Bullock 1½ H. P. motor. The Christonsen concentrator is the fourth. A 3 H. P. motor is provided for the operation of the feeder, elevator, distributer and screen.

The special ores which require grinding are handled by a muller quartz mill working in conjunction with a rock breaker and a sand pump which elevates the pulp to the different concentrators.

The present experiments with the black sand are expected to point the way for a profitable operation of dredgers in many localities where such apparatus were employed in the past, but where the operations did not yield a sufficient return when gold alone was sought. Should the Geological Survey devise means whereby not only the gold, but iron, platinum and all other minerals may be saved, these by-products will supply a satisfactory margin of profit in operations which, under the old conditions, could be conducted only at a loss. Moreover, it has already been demonstrated at the concentrating pavilion that the methods being followed by the Government officials would yield, in addition to the other minerals, an increased amount of gold. The experimental station at Portland has tested considerable quantities of tailings from various dredger districts, and in every instance the increased yield of gold has been, as Dr. Day says, "Too much for the dredger owners to lose."

One of the main purposes of the Geological Survey experiments and the one most prominently mentioned in the preliminary circular sent out from Washington to mine owners is the development of a home source of supply for the platinum market. It has, of course, long been known that platinum existed in commercial quantities in the Pacific coast black sands, but there has been lack of knowledge as to an efficient method of concentration and treatment. At present the United States imports more than 95% of all the platinum used, the annual valuation of the imports being in the neighborhood of $2,000,000, and, inasmuch as the chief source of supply in Russia has been practically closed by the Russo–Japanese war, it is especially desirable that the industry be developed here if possible.

Ranking with, if not exceeding, the platinum project in importance, however, is the partial promise that the present experiments with the black sand will disclose a source of iron ore supply which will foster the development of the iron and steel manufacturing industry on the Pacific coast to considerable proportions. The experimental plant at Portland will, in the course of its operations, secure large quantities of iron ore, and an effort is to be made to induce one or more blast furnaces on the Pacific coast to take the iron ore product from the concentrators at Portland and treat it so that an early conclusion can be arrived at as to the exact value of this raw material to the manufacturing industry.

THE PROSPECTOR.

Any samples of rock or minerals sent to the Prospector Department will be returned at the request of the sender if stamps are enclosed for this purpose. Some of the supposedly valuable minerals sent for identification are without value, but if desired anything sent will be returned.

The three mineral specimens in one paper box from Homestead, Or., marked 1, 2 and 3, are: No. 1, a greatly altered, granular, eruptive rock, presumably diorite or grano-diorite. The feldspars are completely altered into kaolin and calcium carbonate, and the rock has been subjected to considerable pressure, resulting in deformation and an incipient rude cleavage which, by progressing further, would render the rock schistose. The bright, shimmering appearance noticed on some parts of the rock is due to small scales of white talc. The rock has also been silicified somewhat. It shows no mineral—that is, sulphides of the base metals. No. 2 is a siliceous aplite (alaskite) and contains a little pyrite. It may also carry gold. No. 3 is similar to No. 1, but is still further altered, more siliceous, and contains considerable iron sulphide and probably gold also. The green spots are magnesian silicate, similar to mariposite, and contains no copper. This rock, to all intents and purposes, is ore—though apparently low grade.

The minerals from Yuma, Ariz., are: Nos. 1, 2, 3 and 4, fluorite. The color is not material. The most common color is amethystine, but, as in this case, fluor is also white, bluish green and pink. The yellow crystals (No. 5) are wulfenite, molybdate of lead. No. 6 is anglesite lead sulphate.

The mineral from Dillon, Wyo., consisting of sand and bright, shining metallic flakes and grains, is hematite (iron oxide).

The rock sample with sand from Isabella, Cal., is a coarse sandstone carrying much iron oxide. The grains are quartz and the white sand which had accompanied the rock was nearly all lost in transit, due to careless wrapping. Such things as sand and pulverized minerals should be sent in a secure container.

The samples from Sonora, Cal., are determined as follows: No. 1, a talc schist, with a deposition of the yellowish basic ferric sulphate, with earthy material. No. 2 is mostly kaolin. A portion of this sample contains abundant finely disseminated pyrite.

The rock samples from Randsburg, Cal., are all yellowish quartz, with colorless and reddish colored garnets. The black mineral is iron and manganese oxide. The rocks have the appearance of having been picked up on the surface and look as though they may have come from a coarse-grained granite (pegmatite).

The rock specimens from Unuk river, Alaska, are: No. 1, graphitic schist. The original character of the rock is wholly destroyed by metamorphism. No. 2 is typical diorite-porphyrite. The minerals plainly seen are hornblende and black mica (biotite) in a fine ground mass. These characteristics, without the numerous white crystals of soda-lime feldspar, would characterize the rock as mica diorite, but the addition of the porphyritic feldspar crystals classes the rock as a porphyrite.

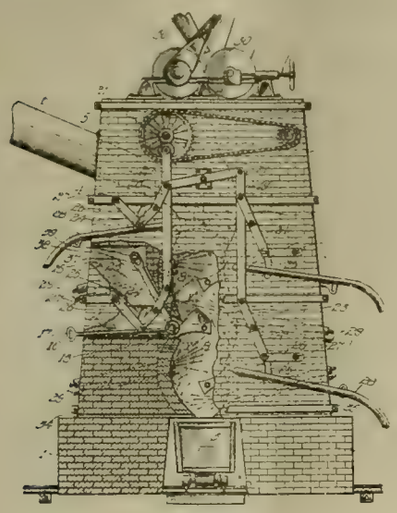
The samples from Havilah, Cal., are: No. 1 is mispickel, the sulpharsenide of iron, with bands of quartz. It may be gold bearing. There is also a small amount of pyrite in the specimen. No. 2 is an altered dike rock, probably originally felsite, now changed to quartz. No. 3 is similar to No. 2, but has not been weathered so much, being evidently from deeper workings. It contains iron sulphide and a small amount of copper sulphide, and considerable arsenical iron sulphide. No. 4 is similar to Nos. 1 and 3, being a siliceous rock altered from a fine-grained eruptive, probably felsite. It contains considerable mispickel.

Mining and Metallurgical Patents.

PATENTS ISSUED JULY 18, 1905.

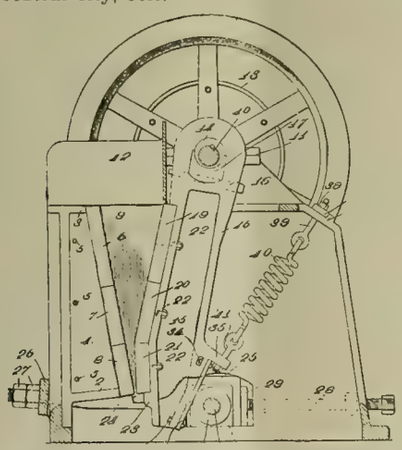
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROASTING FURNACE.—No. 794,837; J. A. Anker, J. H. Watson and P. Evans, Los Angeles, Cal.



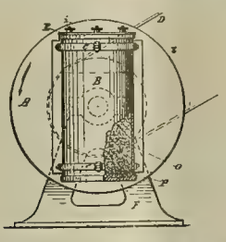
In roasting furnace, vertical sinuous chamber, plurality of retaining shoes projecting into chamber, each retaining shoe having symmetrical portions; tubular shaft extending longitudinally through shoe, wheels on ends of shaft; walls of furnace having recess, inclined rails at bottom of recess, wheels resting on rails, and means for rocking shoes.

ORE OR ROCK CRUSHER.—No. 794,876; E. S. Moulton, Central City, Colo.



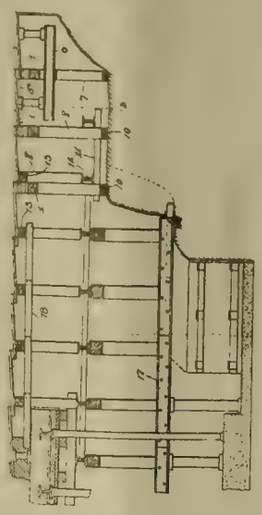
In device of character described, combination with casing, of buffer block secured thereto, crushing plates secured to buffer block, eccentric shaft journaled upon casing, oscillating jaw carried by eccentric shaft, comprising lever member, plurality of crushing plates secured thereto upon one side thereof, removable plate secured to lever member upon opposite side to which plates are secured, flexible member secured to casing and connected with lever member, revoluble member engaging plate carried by lever member and means for moving revoluble member and retaining same in adjusted position.

ART OF TREATING ORE AND GATHERING GOLD OR PRECIOUS METAL DIFFUSED IN THE EMPLOYED MERCURY.—No. 794,552; G. M. Rice, Worcester, Mass.



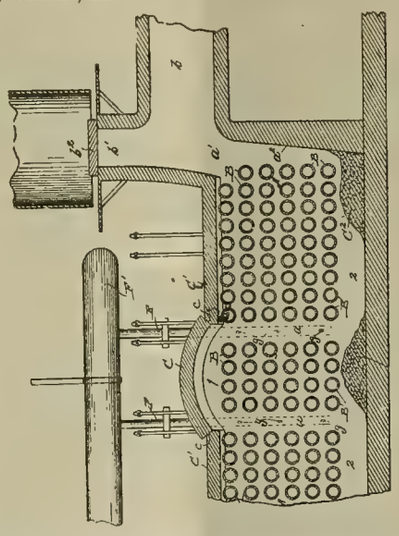
Improvement in art of recovering gold or precious metals from mass of ore under treatment by amalgamation with mercury, which consists in adding to mass of ore previously supplied with water and mercury only quantity equaling about 2% to 5% of weight of mercury of metal capable of being amalgamated by mercury.

METHOD OF TUNNELING.—No. 795,148; J. C. Meem, Brooklyn, N. Y.



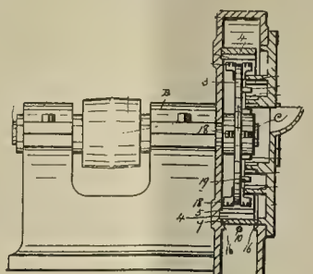
In method of tunnel construction, step consisting in introducing beneath tunnel roof supporting structure having two superposed sets of spacing members, inserting lagging boards through spaces between upper set of spacing members, excavating in front of supporting structure and advancing lagging boards simultaneously with excavation, introducing second supporting structure beneath forward ends of lagging boards when advanced to proper distance, introducing second set of lagging boards through openings between lower spacing members of first supporting structure and between upper spacing members of last supporting structure.

ZINC SMELTING FURNACE.—No. 794,799; E. C. Hegeler, Lasalle, Ill.



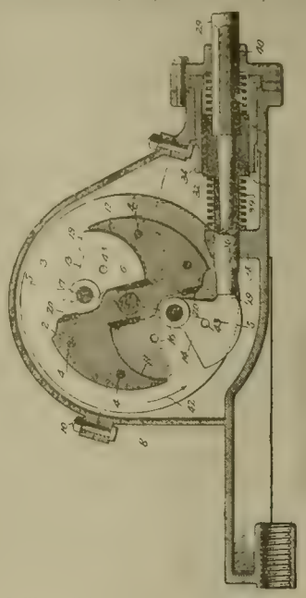
In zinc smelting furnace of class specified, long. horizontal retort chamber through which gases pass unobstructed, except by retorts, in direction of greatest extension and having roof provided with series of recesses, and bottom provided with series of recesses, in combination with retorts arranged between roof and bottom, in space outside recesses.

DISINTEGRATOR.—No. 794,785; W. Cox, Hamilton, Canada.



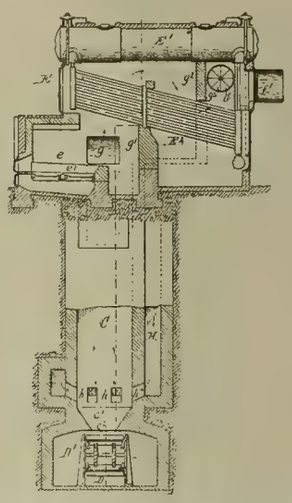
In disintegrator, combination with casing, of an internally corrugated ring in casing having a discharge opening in its lower portion only, guides, sliding gate moving in said guides and having perforated lugs or ears, screw-threaded operating rod journaled in the casing and turning in said perforated lugs, nut between the lugs in which the screw threads of the rod turn, rotary member in the casing, and heaters on said rotary member which are located inside the said ring.

DRILL STRIKING MECHANISM FOR ROCK DRILLING ENGINES.—No. 794,930; L. Durkee, Denver, Colo.



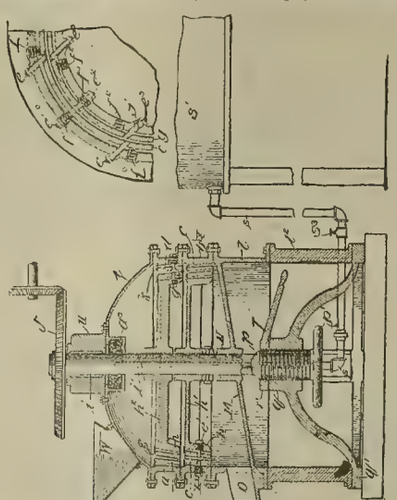
In drill-striking mechanism for rock drills, disk having recesses therein, hammers pivoted in disk beyond axial center, and arranged and adapted to swing out into drill-striking position by centrifugal force and to recede into recesses out of drill-striking relation after drill-striking stroke.

SLAG FURNACE.—No. 795,032; O. S. Garretson, Buffalo, N. Y.



Combination of slag chamber adapted to hold pile of loose congealed slag and having air passages communicating with upper and lower portions, slag-congealing rolls arranged at upper portion of chamber for receiving molten slag, congealing same and delivering congealed slag to chamber, and means for causing air to flow through passages and pile of congealed slag in chamber.

GRINDER.—No. 794,714; F. J. Hoyt, Redlands, Cal.



Combination with flanged and rotatable discs provided with sectors of radially adjustable spring cushioned grinding faces, of opposed non-rotatable spring cushioned radially adjustable grinding faces.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

A dispatch from Dawson announces a stampede to California, Leonard and Rainy creeks in Glacier district, 50 miles west of Dawson, and reached via Forty-mile Roadhouse. Pay dirt on the creeks was struck on the rim. On California and Leonard creeks 15 cents a pan was obtained. On Rainy 4 cents a pan was found. Discoverers were J. Leonard and J. Marcotte. California was stampeded six years ago, but produced nothing at that time.

Regarding the cost of prospecting in different localities, a recent report of the United States Geological Survey says that in the Juneau district prospect shafts must be square set, and cost on an average $6 per foot, and in heavy landslide $20 a foot. In the Porcupine district the cost of a cut 25 by 12 feet and 40 feet deep is $50 per foot, and that of an 8 by 8 foot shaft is $20 per foot. In the Sunrise and Chisna districts ground is prospected by open cuts. A cut 50 feet in length is reported to cost $2000. At Atlin ground is prospected mostly by drifting. On McKee creek tunnels, timbered and lagged, cost $3.50 per foot. On Spruce creek the cost of posts and caps, 10 inches thick and 6 feet long, is 50 cents each; lagging, 10 cents each. On Gold Run thirty 6-inch holes are said to have been drilled to a depth of 32 feet by a churn drill (cost, $3500, laid down), at the rate of $1 a foot. In the Klondike drifts to prospect the bench gravels cost $7 to $8 a foot, timbered, and shafts from $5 to $10 a foot. In timbering, three sets of posts, sill, cap and lagging are put in for $6, and as one-half cord of wood is used to a set the whole cost is $7 per set. In frozen creek ground two men, working three shifts, sunk a pit 5 feet square, 28 feet deep, using about 2 H. P. steam during thirty hours. On Forty-Mile creek, thawing ten hours, two men take out on an average 4 feet a day, the shaft being 5 feet by 3½ feet in dimensions. On American creek prospecting is very difficult, as running water is always found at bedrock, even in the coldest weather. In the Forty-Mile district shafts averaging 3½ by 6 feet, untimbered, cost from $3 to $5 per foot. Seven shafts 4 by 8 feet and 23 feet deep cost $2000. A shaft 7 by 3½ feet and 20 feet deep costs $5 per foot, the thawing being effected by means of wood fires and steam. In the Birch Creek district shafts thawed down by wood fires to a depth not exceeding 20 feet cost $5 per foot. On Mastodon creek, in this district, eleven pits 3 by 6 feet and 20 feet deep, cost $650. Twenty pits 3 by 6 by 13 feet cost $7 per foot. The differences in cost here are due to the varying amount of permanent frost in the ground, prospecting always being cheapest in solidly frozen ground. On Mammoth creek 100 pits 10 feet deep cost $5 per foot. Wood fires were used, 2 feet being sunk each day. No timbering was required, and labor was paid $10 a day. In the Fairbanks district the prospect shafts cost $7 to $10 per foot. Timbering is generally necessary, but very light poles are used either as lagging or cribbing. The best system is to put in 6-foot sets of 3-inch poles, and outside of these to lag with 2-inch poles vertically, filling in solidly between the poles and the muck or gravel with moss. Shafts cribbed with poles horizontally are more likely to get out of plumb. Four shafts sunk on lower Fairbanks creek cost $5 per foot, and were 32, 44, 53 and 54 feet deep. On Cleary creek a shaft 4 by 6½ feet and 75 feet deep (hillside claim), cribbed with 3-inch poles, cost $560. Wood fires were used in thawing. On Pedro creek nineteen pits 3½ by 7 by 12 feet cost $1140, and on an adjoining claim pits 3 by 6 feet and 18 feet deep cost $6 per foot. The light timbering and moss filling used in the Fairbanks mines is to prevent the muck walls from thawing and caving. In the Rampart district thirty pits 3 by 6 feet and 20 feet deep cost from $75 to $100 each. The ground was partly thawed, but required no timbering. In the Nome district, on account of the entire lack of native timber, shafts are cribbed with 1 or 2-inch planking, set close together, no sets being used. On the Snowflake bench claim, on Anvil creek, the cribbing was re-enforced by 2 by 4-inch posts in the corners. Five dollars per foot is the average cost of 4 by 5 shafts, timbered, in unfrozen or partially frozen ground. On Bonanza creek, near Nome, pits in the shallow creek bed, 3 by 7 feet and 7 feet deep, are said to cost 50 cents per foot. The ground is only lightly frozen and requires no timbering. On Ophir creek, in the Council district, it costs on an average $5 to sink pits 7 feet deep. In the northern part of Seward peninsula the ground is solidly frozen. In the Kougarok district pits 35 feet in depth, with steam thawing, cost $8 per foot, and require no timbering. In the Candle or Fairhaven district, adjacent to Kotzebue sound, twenty-eight pits 12 to 15 feet deep cost $4 a foot. It was necessary to thaw to bedrock. The equipment cost $500.

ARIZONA.

Graham County.

Work has been resumed at the Ash Peak mines, near Duncan.

Maricopa County.

(Special Correspondence).—A small mill is being put in by J. E. Maddox on his property in the White Tank mountains, north of Buckeye. Should this prove to be a success, a 5-stamp mill will be put in.

Buckeye, July 24.

(Special Correspondence).—Geo. Hamlin brought in another bar of bullion from the Relief mine. This is about the only producing gold mine in Maricopa county at the present time.——Eastern capitalists are visiting the Mormon Girl mine in the Cave Creek district.——In the Union district a small stamp mill is to be put in on a property north of the old Union mine.——W. E. Williams of Douglas is working a gold property adjoining the Union property.

Phœnix, July 24.

Pinal County.

The Ophir Con. G. & C. M. Co. has been formed to work mines near Twin Buttes. J. B. Daugherty is president and J. T. Dunlap secretary and treasurer.——It is reported that the Saddle Mountain M. Co.'s new 150-ton smelter, near Dudleyville, has been started.

Yavapai County.

The Great Republic M. Co. is putting in a 40 H. P. gasoline engine to continue sinking their shaft on Turkey creek, near Prescott.

J. R. Thomas, of the Black Hills C. Co., has started sinking the main shaft, near Jerome, to a depth of 1000 feet. This shaft is now down to a depth of 350 feet.—— It is stated that the Copper Chief M. Co. will build a smelter on Equator hill, near Jerome.

CALIFORNIA.

Amador County.

At the Climax mine, near Pine Grove, sinking 100 feet deeper and the opening up of levels at this depth show the ledge in undiminished size and richness. The putting up of the 10-stamp mill is being pushed. The company has bought the Reward mill near Pine Grove, and is hauling it to the Climax. The old 2-stamp mill has been sold to parties near West Point.——At the Gold Top gravel claim at Pine Grove men are putting up the necessary flumes to bring water to the mine. Hydraulic operations will be started as soon as the ditch is completed.

Butte County.

Two new dredgers will be built in the Oroville district. One will be on the Jacobs' orchard, with O. B. Perry in charge of the construction, and the other on the Baggett place, south of Oroville. Mr. Baggett has signed a contract for a 7-foot dredger.

Calaveras County.

Work is to be resumed August 1 at the Blue Gravel mine near San Andreas. W. H. Steffler has been chosen secretary vice B. C. Miller resigned.——The Red Gold mine at Murphys is being unwatered preparatory to resuming sinking.

Del Norte County.

It is reported that the company prospecting the gravel near the mouth of Klamath river have found the ground rich enough to warrant working with a dredger, and a small one will be built for further prospects along the river. The gravel bed, where drilling was done, is 75 feet deep.

El Dorado County.

A. F. Buchanan's Zantgraf Extension mine, near Loomis, is producing good ore. E. B. Quigley is superintendent.

F. M. Phelps, superintendent of the Cedar Creek mine, Fairplay district, has commenced work on a 1000-foot tunnel which it is expected will tap the center of the channel.——The Sliger mine, in Greenwood district, has resumed operations under the superintendency of W. H. Grenell of Bath, Placer county.——The Blue Ravine mine, Folsom district, is to be reopened and worked through a new shaft 1 mile from the old works, and preparations are being made to move the machinery to the new location.——At the Rosencrans mine, near Garden Valley, near Placerville, sinking is being pushed with two shifts. A whim has been put in at the shaft which is down 70 feet.——The Alpine mine, Garden Valley, is being developed.

Kern County.

P. Sartiat of Bakersfield has contracted for a 10-stamp mill on the Black Bob mine, in the San Emidio region, near Tejon.

Preparations are being made by the Southern Pacific Co. for improvements on its oil pipe lines in the Kern river fields, which it is expected will facilitate the transportation of oil. Wherever oil is transported through pipes difficulty is experienced, due to the resistance caused by water in the pipes. The new pipes which the railroad company is preparing to put in are rifled like a rifle barrel, the theory being that the revolution of the oil while traveling through the pipes will keep oil, instead of water, at the surface of the pipes through centrifugal force, the oil being the heavier fluid, and that resistance will be overcome. The machine which is to be used for the rifling will arrive at Bakersfield on Aug. 8.

T. McCarthy and others are working a tungsten ledge near Randsburg.

Lassen County.

The Nanney ranch, at Mountain Meadows, has been bonded by a dredging company of Oroville and drilling and prospecting to determine the probable richness of the tract in gold is under way.

Mariposa County.

Edward J. and Eugene J. Mahoney of the Mountain Queen G. M. Co., working claims on Good's gulch, near Mariposa, have a shaft 112 feet deep on the Little Utica. ——Arrangements are being made to drive a tunnel of 400 feet on the Sunshade, the work to be done by contract.

Nevada County.

Superintendent F. B. Hill of the Two Counties mine, north of Nevada City, expects to have the new mill in operation next month.——A project for turning the channel of the Middle Yuba opposite the mill at Delhi has been formed by G. E. Alexander of Denver, Colo.; G. M. Graves of Chicago; J. S. Wilbur of San Francisco; S. Poorman of Alameda, to work a gravel claim.——The Bullion mine in Grass Valley has been troubled with water, but Superintendent G. Mainhart has got the water down to the 1200-foot level and says that the remaining 300 feet will soon be cleared.

Placer County.

(Special Correspondence).—It is reported that the Dairy Farm copper gold mine has been sold to the Guggenheims. The price is not stated, but is thought to be $250,000.

Lincoln, July 25.

The Jupiter mine at Iowa Hill has closed down temporarily.——The gravel at the Buckeye mine, above Forest Hill, is said to be averaging $5 to the car. They have both the blue and the white lead, and it is believed are on the old Morning Star channel.

Plumas County.

(Special Correspondence).—The New York mill at Greenville has been temporarily closed down for repairs. ——The 15-stamp mill at the Droege mill in Indian Valley is running.

Greenville, July 25.

San Bernardino County.

Notices have been sent out by J. H. West of Needles to the desert sections of San Bernardino county asking for such information as may be necessary for the placing of metallic guide posts for the guidance of the prospector that he may find water. The State has appropriated money for the manufacture of the metallic posts and sign boards and the counties are empowered to place the boards.

San Diego County.

C. O. McCarroll of Mesa Grande has sold his tourmaline property of 604 acres to Los Angeles men.

Sierra County.

Work is to be resumed at the Deep Blue gravel mine, near Alleghany, under the management of J. W. Morrell, who has also commenced work at the Mabel mine in American Hill.——Kieffer Bros. have resumed operations on the Gibraltar in the headwaters of Canyon creek, near Table Rock.

Siskiyou County.

A. C. Brokaw of Fort Jones will put in a 10 stamp mill at the Advance.——Most of the hydraulic mines of the Salmon district have been closed down because of lack of water. The average cleanups have been good.

Trinity County.

J. H. Porter has resigned as superintendent of the Fairview mine, Pappoose, and has bonded the Bonanza mine, at Trinity Center, which he will actively develop.

Tuolumne County.

The Republican mine, near Jacksonville, has a small force doing development work, and the mill is closed for the present.——The Longfellow mine, Big Oak Flat, has completed pumping arrangements by which water will be furnished for the mine and mill. A little delay has been caused in the starting of the new ten stamps by the non-arrival of some of the parts.

COLORADO.

The Yankee Con. M., M. & T. Co., at Yankee, have overhauled the mill and plans to put in an aerial tramway, connecting the mine and mill.——The Manhattan tunnel is being worked by contract.——R. McGillvray has thrown up his contract for driving the Central tunnel a mile farther, because of the low bid he made on the work and the unusually hard character of rock in the drift. As a result, the Big Five Co., which owns the tunnel, has closed down the power plant at the mouth. No action will be taken towards the resumption of the work for several weeks, until after the meeting of the stockholders, which will be held during August.

Clear Creek County

The trail to the Arapahoe mines, in East Argentine district, which was badly damaged by snow slides, is being put in shape for the transportation of ore and shipments will soon be commenced to Silver Plume.

The Harris lode, East Argentine district, near Georgetown, which has been operated under lease by W. F. Farragher for the past three years, has been leased to J. Keating. He intends to work in the raise, now up 50 feet, and to continue the tunnel.

The Lombard mine, at Yankee, is being worked continuously with three shifts.

Chaffee County.

Manager Philbrick of the Shawmut Con. Copper Co. has contracted to supply the Canon City smelter with 500 tons of copper ore monthly from the Sedalia mine, near Salida.——It is reported that work is to be resumed at the Jasper mine in the Turret district. The Independence, Vesper, Copper King and Badger are being worked.——J. B. MacDonald is shipping regularly from the Madonna mine, near Monarch.——The Monarch tunnel is in 1450 feet. It is to be driven 6000 feet.

G. H. Van Wagoner of London, O., president and general manager of the Golden Fleece mine, in the Manoa district, 12 miles north of Salida, has started work, after equipping the mine.

Custer County.

In Junkins park, near Silver Cliff, the snow has gone and all parts of the park are accessible to prospecting. Development work is being done.——P. M. F. Finnis has organized the Fountain Park G. M. & M. Co., to work claims in the district. Men are driving a tunnel that will cut the dikes at depth.

Dolores County.

The Western G. M. & M. Co. contemplates putting a small hoist on their mine near Rico.

Eagle County.

Mining at the head of Lake creek, at Silver City, is going on. The claims are all above the timber line. J. E. Miller of Leadville has eighteen claims which he has leased to Eastern people. A tunnel is being driven from the foot of the hill 100 feet and will be driven 1100 feet farther.

El Paso County.

As soon as the ore on hand is treated, the Standard mill at Colorado City will be closed down. The reason given by C. M. MacNeill, vice-president and general manager of the United States Refining & Reduction Co., which owns the property, is shortage of ore receipts. About 200 men will be thrown out of employment when the mill shuts down.

Gilpin County.

Since the new rule went into effect on the Colorado & Southern road concerning shipments of ore and concentrates on the Clear Creek division of the line, wherein the marked capacity of the car governed the freight charge, regardless of how much less the shipment was, efforts have been made to have the road rescind the order, as it worked a hardship on many of the small shippers on the line. The Colorado Mine Operators' Association took the matter up with C. L. Wellington, general traffic manager of the road, with a result as follows: Effective July 5, 1905, the following carload weights on ores and concentrates shipped from points on the Clear

Creek division of the C. & S. railway, will govern: On cars under fourteen tons capacity, twelve tons minimum. On cars over fourteen tons capacity, twelve tons minimum.——Manager Anderson of the Gold Dirt M. Co. in Independent district reports that the new mill in Gambell gulch will be running on ores about August 1st.——Work has been resumed on the Gold Dollar property, owned by Jenkins, Daly & Nelson of Central City. The main shaft on the Happy Hollow, operated by the Inter-State Con. M. Co., near Gambell gulch, is down 50 feet and, as soon as the necessary timbering work can be done, Superintendent Churchill intends to crosscut towards the north.——Superintendent C. H. Karns of the Empress mine, near Lake gulch, reports that they have reached a depth of over 300 feet in their shaft, are making good headway in cleaning out and retimbering the shaft and expect to reach the bottom, a depth of about 400 feet, within two weeks.——Work is being rushed on the new shaft building on the East Notaway mine of the Town Topics M. Co. in Russell district, to replace the large shaft building, which was destroyed by lightning and fire.

The Imperial M. & M. Co. has put in a 7-drill compressor at the Mackey mine in the Pine Creek district.——The Newfoundland G. & S. M. Co. has men at work extending the east 900-foot level as well as stoping in the 800-foot east workings, with four leasers besides the company men. They are shipping smelting, milling and concentrating ores to Black Hawk. G. W. Mabee, Jr., is superintendent.——The Gladstone and Firenzi claims, in Illinois Central district, near Central City, have been under a lease and bond by J. H. Heinz of New Marion, Ind., who has appointed Henry Ehrhardt in charge of the property. On the Gladstone property the main shaft is down 225 feet and as soon as machinery can be put in the lessees intend to clean out the shaft and sink it 100 feet deeper. The new plant will consist of a 25 H. P. hoist and 35 H. P. horizontal boiler.——The Firenzi shaft is down 90 feet and a whim is to be put in.——The work of cleaning out the shaft on the Homestake in Lake and Russell district, near Central City, is under way and as soon as the bottom is reached, a depth of a little over 300 feet, the Homestake Co. intends to commence sinking. B. G. Granville has charge.

Gunnison County.

The Raymond T. & M. Co., operating near Ohio City, have ordered a 100-ton mill as soon as it can be built, based on the plans and specifications being prepared by C. Neicel of Denver. In the course of 2000 feet of the Raymond tunnel a number of fine veins have been cut, some of which have been developed by laterals from the tunnel. To ascertain their value in bulk, Manager E. M. Lamont sent several lots to the Denver Ore Testing & Sampling Co., N. C. Bonnevie manager, and himself watched the entire process of treatment. The results were satisfactory, showing that all of these ores will pay well when properly handled. The value originally was $10.60 gold, 2½ ounces silver, 3.6% lead and 2.8% zinc. It amalgamates $4 per ton gold, the concentrates carrying 3 ounces gold, 14 ounces silver and 20% lead. The zinc product was not saved, being within the penalty limit. Neicel will have charge of the construction and operation of the mill.

The Joplin mine at Spencer is being worked by F. P. Hott.——B. Pomel of Spencer is working the Neglected lode.

The machinery for the aerial tramway for the West Gold Hill M. Co. is being hauled to the property from Pitkin. This tramway when completed will be 2250 feet long without a tower, and will convey ore from the mine to the mill and 65-ton cyanide plant.——Wm. Friend has men working on the Grand Prize, near Pitkin. The shaft is being sunk and is down 70 feet.——The Forest Hill mine and mill are to be started up. The values are mostly in zinc.——The Quartz Creek mill, near Pitkin, is being put in shape by A. B. Clark for treating ore by cyanide.

The old Montezuma mine, between Crested Butte and Aspen, is being examined. —— J. E. Ericson, manager of the Copper Creek M. Co.'s properties near Gothic, has started work.

Hinsdale County.

The Fidelity M., M. & P. Co. has been formed at Lake City by C. J. Fox of Philadelphia, Pa., T. Henneberry of Denver and others to develop the Bull Hill claims and the Alhambra placer in Four-mile park. They intend to build a wire tramway to convey the Bull Hill ore to the Alhambra placer, where the reduction works will be built.

Lake County.

The different properties on Rock hill, Leadville, are producing high-grade lead ore, and the different shafts that are going down are making good headway. The Reindeer is shipping 100 tons daily and development work is being carried ahead in different parts of the mine. The Dome is shipping and developing the ore body to the north, and as work proceeds the ore shoot becomes more defined. The Murphy shaft is down to the necessary depth and drifts are being run under the ore body. A shipment has been made from the Bessie Wilgus and the drift has been run to the south under the ore shoot and upraising started. New machinery is being put in at Buffalo-President, on the Iowa gulch side of the hill, and when completed will be in position to handle the water struck recently in the shaft at a depth of 300 feet. The Nil Desperandum is in ore in both drifts.

Mineral County.

Ore is being taken from the Happy Thought mine at Creede, through the Worcester tunnel, and is being treated in the Humphreys mill. It is reported that the Worcester tunnel, now in over 10,000 feet, is to be continued. A slimes plant is being added to the mill.

Ouray County.

Electric drills are to be put in the Blowout tunnel of the Ouray Con. M. Co., ¾ mile from Ouray. The tunnel is in 475 feet and is to be run 2000 feet farther to cut ledges at a depth of 1600 feet. J. H. Tumbach is manager at Ouray.——The Atlas M. & M. Co.'s tunnel, north of the Revenue mine, is in 600 feet. F. Carroll of Ouray has charge.

In the Genessee tunnel of the Red Mountain R. M. & S. Co. a crosscut from the main tunnel and 2100 feet from the portal has cut a 7-foot body of ore, in depth 700 feet from the surface, where it outcropped.——G. Crawford of Red Mountain expects to unwater the old shafts of the Yankee Girl, but the volume of water is so great that it will of necessity be slow. If the entire amount of water was broken into at once it would flood the tunnel. It is probable that the reservoirs of water will be tapped with diamond drills and drawn off gradually.

Park County.

(Special Correspondence).—Several properties are operating in Buckskin gulch, among them being the Fannie Barret, A. Crown manager. This company is running a tunnel to tap the old stopes on the property which were opened twenty years ago. This tunnel when completed will be 1000 feet in length and will tap the vein 800 feet below the surface. The property is on Loveland hill.——The Red Lion is under lease to S. A. Offerson & Co. and two to three cars per month are being shipped. Near the Red Lion, A. A. Bissell is operating the New York and shipping about ten tons per day.——A. B. Ogden is operating the Sweet Home mine. This property has been idle for many years, but during the early days of the mine considerable ore was shipped to Swansea, Wales. Power drills will be put in, also aerial tramway for handling the output of the mine.——The old Ling mine on North Star mountain is being operated in a small way, but arrangements are being made to put on a larger force by Manager O. Eldredge. The Wheeler mine on the south slope of this same mountain is also under the management of Eldredge and operations will be increased about August 1. Small shipments are being made from both the Ling and Wheeler.——R. A. Morrison of Denver, Colo., president of the Montgomery G. M. & M. Co., is driving a tunnel under North Star mountain to strike the Ling vein and other veins on their own property, which they have opened up on the surface. The tunnel is in 620 feet and about 2 feet per day is being driven by hand work. Work on the tunnel is being done under contract by Blank & Larson.——A. M. Anderson has organized the Pawnee G. M. Co., and is operating the Helen Gould Nos. 1, 2 and 3 and Goldsmith claims. This property is on London mountain. J. M. Kuhn is manager and T. E. Schwarz, consulting engineer.——The Oliver Twist Co., near the London Co., is developing on London ground.——The 10-stamp mill at Montgomery, 6 miles above Alma, on the Platte river, is operating under the management of H. Eddy on ore from one of the mines belonging to the company.——It is understood that J. A. Shinn of Leadville is in Pittsburg, Pa., making arrangements for money to carry through his tunnel scheme to pierce Mosquito range in the Horseshoe district.

Alma, July 20.

(Special Correspondence).—On the Platte river, between Alma and Fairplay, the Snow-Storm Hydraulic Co. is operating its placer ground. During the beginning of the season they sunk sixteen drill holes and eleven shafts to bedrock, a distance of 40 to 60 feet, and tested the ground thoroughly. They have driven a tunnel 600 feet under the hill to connect with a 40-foot shaft. From this shaft and through the tunnel they have built a double flume, which extends from the tunnel entrance. The flumes are each 3 feet wide and 3 feet deep and the first 100 feet is composed of Angle iron riffles. Owing to delay in receiving pipe from the manufacturers, they have been delayed in getting their giants, which will consist of two No. 1 and one No. 5, in operation. The gravel and sand are washed from the pit into the shaft and down through the flume. As work proceeds in the pit, the shaft will be done away with and later on the present pit will be used for a dumping place. The giants will operate under 275-foot head of water taken from Platte river. They are also putting in an electric light plant.

Fairplay, July 24.

Pueblo County.

The two zinc concentrating mills of the United States Zinc Co. at Pueblo are completed and running continuously. One uses the dry crushing and the magnetic separation method, the other the wet process, employing Willfey tables. E. Anderson is agent. The concentrators have a capacity of 100 tons a day. They can smelt 25% to 30% zinc ores carrying clear values in gold, silver and lead, without concentration.

Saguache County.

The Shawmut Gold, Silver, Copper M. & M. Co. has put in a hoist preparatory to sinking in the Bonanza district, 16 miles from Villa Grove. The Bonanza and Morning Star mines are being developed in the same district.

The Shawmut mines in Bonanza district, 12 miles south of Alder, have been sold for $100,000 to W. P. Black, G. C. Moore, E. E. Hume, H. J. Welman, Chas. Eckles, C. Renner and H. A. Bush, of Cambridge Springs and Erie, Pa. W. P. Black has been chosen general manager, and is putting in a 100 H. P. steam hoist.

San Juan County.

The 6000-foot crosscut tunnel of the Stoney Pass M. Co. has been driven over 1300 feet toward a lead-silver vein in Prospect basin. J. W. Dolan of Silverton is superintendent.——Superintendent M. M. Gregg is drifting on the Magnolia vein from the 1200-foot point of the Hurley tunnel, near Gladstone.——It is reported that E. L. Thompson of Silverton, manager Delayed M. & M. Co., intends putting in a compressor and drills at the company's mine near Rockwood.

Malchus Bros. & O'Neil are making preparations for a 75-ton mill, to be put on the Mayflower. The ore, being a copper-gold proposition with small lead-silver values, is satisfactory for concentration.

Kramer Bros. & Carmichael, who recently took a lease on the Silver Ledge mine and mill at Chattanooga, are employing thirty men. The mill is taking sixty tons daily of crude ore from which the concentrators return fifteen tons of lead and eight tons of zinc, after the Blake electric zinc separator has done its work.

The Grand Mogul Co. has under way improvements on its property, near Gladstone. Excavations are being made for a 200-ton mill. The ore is first to be crushed under 1350-pound stamps, after which it is passed over amalgamating plates. It is then further reduced in Boss grinding pans, after which it is carried to the concentrating tables, where the remaining values are saved. The product is then passed through the drying ovens, when it is ready for shipment. The mill will be connected with the mine by an aerial tram, 8500 feet in length.

San Miguel County.

Work has been resumed at the Ophir Con. M. Co.'s mines near Ophir, under the direction of W. B. Ladd, representing Eastern directors. G. E. Driscoll is experimenting with ten stamps of the mill as to the best method of treating the ore.——The upper levels of the Butterfly-Terrible are being worked by leasers, their ore being treated in the company's mill. Manager J. F. Keating of Ophir is continuing the crosscut tunnel.——J. O'Brien of Ophir has charge of the D. Gale M. Co.'s work in Swamp canyon.——Ore from the Montezuma-Cariboo mines is being milled in the Yellow Mountain mill, near Ophir, under the superintendence of O. Ericksen.

Summit County.

(Special Correspondence).—For a number of years Summit county has been noted for its placer mines. At present there is perhaps as much, if not more, lead mining than placer work, especially in the neighborhood of Breckenridge. The American Gold Dredging Co., W. W. Dyar manager, is operating several drills on their property near Swandyke, prospecting with a view of adding several new dredgers to their equipment the coming year.——In French gulch the Lincoln G. M. Co. is operating its placer ground, using hydraulic giants. It has a lease on the water from the Gold Run ditch which belongs to the American Co. It has about 2000 inches of water at present and it is thought that the supply will continue till cold weather sets in, on account of the large volume of snow in the hills. The flume of this company is now about 2000 feet in length. It is preparing to put in a hydraulic elevator for handling the water and gravel from its pit.——The French Creek G. M. Co. is driving a crosscut tunnel in Baldy mountain, to tap some rich veins which are known to exist at the surface. The tunnel is now in 1320 feet. Electric drills are being used in doing the work. The tunnel is 5x7 in the clear. The work is being done at present by E. T. Brooks, under contract from the company. It is understood the company intends to keep driving ahead until it proves whether the ore goes down with depth. Should good paying ground be opened up, it will be the means of starting other enterprises along the same line of work.——In the same gulch nearer Breckenridge, on Mineral Hill, is the old Wellington mine, being operated by the Colorado & Wyoming Dev. Co. The crosscut tunnel, which is 650 feet in length, cuts the "Big" vein which carries zinc and lead. There are 650 feet of drifting on the vein and 400 feet of raises. One shoot in this mine is 14 feet wide and a 24-foot winze is sunk on the shoot. Mostly development work is being done on this property. They are able to ship enough ore from the upper workings to pay for all development work. R. W. Foote is manager and C. F. Aultland superintendent.——B. S. Revett is getting his big dredger under operation in French gulch, and it is expected to increase the output of the placer mines in this section.——The Old Union M. & M. Co. has five claims and millsite on Mineral hill. The company has sunk its shaft to a depth of 450 feet and now driving a crosscut from the gulch side to connect with the shaft, which will require some 1100 or 1200 feet to reach. In driving the tunnel they have met with a few setbacks which have delayed their work materially. The company has recently completed a new mill at the mouth of the tunnel. As soon as the tunnel is completed, the mill will be in shape to receive the ore from the mine. The mill will have a capacity of 100 to 150 tons per day. It consists of crushers, rolls, screens, jigs and tables. A. E. Keables is manager.——The Gold Dust Mines Co., M. W. Hoyle manager, has been working the old Puzzler mine, near Breckenridge, but recently closed down until they can make arrangements to put in a mill. Manager Hoyle is now in the East, endeavoring to raise the necessary capital.——On Mineral hill the Abundance M. & M. Co. is putting in a new hoist preparatory to doing a large amount of development work. The shaft is down 175 feet but will be continued deeper. At the 150-foot level they are crosscutting each way from the shaft to the side lines and have cut veins on each drift, but are making no efforts at present to develop them. John G. Goodier is manager.

Breckenridge, July 24.

(Special Correspondence).—The Masontown M. & M. Co. expect to start operations in the nextmonth on their property at Frisco.

Frisco, July 25.

Teller County.

The Lonaconing property on Beacon hill, Cripple Creek, is looking better than it has for many months. The operators have proved that the ore shoot was not worked out south of the shaft, and the developments show that the shoot took a pitch another way and is now showing mineralized rock.——Machinery is being put in at the Pay Rock, on Rhyolite mountain, Cripple Creek, preparatory to sinking from the 200-foot level.——The machinery has been put in at the Blue Flag mine of the Blue Flag M. & M. Co. by Manager J. F. Erisman.

Marshall Bowers proposes to sink the Pharmacist shaft on Bull hill, Cripple Creek, to a depth of 1000 feet. A 6-drill compressor is to be put in.——A hoist capable of lifting from a depth of 2000 feet is to be put in at the Shurtloff mine of the Findley Con. Co. at Cripple Creek.

IDAHO.

Boise County.

J. K. Woodburn, who purchased the concentrates produced by the War Eagle mill at Grimes Pass, found them to be too low grade to bear the expense of wagon haul to the railroad, freight charges and treatment. Since then he and Eugene Grice have been experimenting to discover an economical and successful method of extracting the values. After several unsuccessful attempts they found that by roasting values were saved by cyaniding. They have shipped an outfit to

Pioneerville and will begin operations at once. The concentrates will average $40 per ton, and it is thought they will be able to save 85% at a cost of $5 per ton. There are about 200 tons at the mill from the Bruiser and Pheasant mines. Should this work prove a success it is probable that these mines will be started up.

The American Exploitation Co. is working the Nellie claims, in the Pearl district, with M. E. Hopkins as manager.

Elmore County.

H. Le Bar, manager of the Mountain View property, near Pine, reports that the 10-stamp mill is almost completed and the electrical plant is on the road. A cyanide plant is to be built.

Idaho County.

H. Thorpe, manager of the Gott M. Co., operating placer properties on Grouse creek, between Resort and Warren, states that the big ditch built by the company, which heads in Secesh creek, is being completed and it is thought water can be turned in by September 1. The ditch will be 4 miles long, 7 feet wide at the top, 4 feet at the bottom and 3 feet deep. There yet remains 500 feet of excavating to be completed, and the work so far has been done, including the clearing of a 20-foot right of way, with thirty-five men since June 1. J. J. Toler has sold his interest in the company.

M. F. Tytler, manager of the Seattle & Idaho M. Co. at Dixie, has resumed work on the Comstock under bond. The company intends to put in a cyanide plant.

Kootenai County.

H. M. Williams, general manager of the Ponderay Smelting Co., owning the new lead smelter, near Sandpoint, says that all the machinery except the electric equipment is on the ground, and the plant should be running in two months. D. T. Parker is superintendent. About 25 men are employed. People interested in the Ponderay Company are developing in the Minerva and the True Blue, nearby, and are also driving on the Venezuela, and have let a contract for continuing the crosscut 300 feet.

Shoshone County.

Good concentrating ore has been struck in the lower workings of the Paragon mine, 4½ miles east of Murray. L. W. Stedman is manager. —— The New Hope M. Co. is developing claims 2 miles from Osburn, on New Hope gulch. On the south vein a tunnel has been run 240 feet. The lower tunnel is a crosscut intended to cut the ledge 300 feet below the workings above and has been run 420 feet.

The old tunnel on the Phœnix mine, near Osburn, has been cleaned out by the German-American M. Co. of Spokane, Wash. A compressor with two drills has been put in and the contract let for 150 feet of tunneling, extending the present tunnel, which is 640 feet. C. E. Mitchell of Spokane, Wash., is interested.

Tooele County.

The Overland property at Sunshine, which was sold to Denman Blanchard of Boston for $37,500, is to be started again. The mill is to be overhauled. M. A. Sheets has been named as superintendent.

MONTANA.

Broadwater County.

The Edward F. Co. is building a stamp mill and putting in cages and cars at its property at Hassell.——The Mason syndicate have started their concentrator at Mason.——The concentrator on the East Pacific at Winston will be started by August 1.

Fergus County.

The Armstrong property, at Kendall, is being developed by J. A. Irwin, of the Spokane Diamond Drill Contracting Co.——W. G. Moore has men at work on the W. G. Norman ground at Kendall.——A. S. Wright has purchased twelve claims adjoining the Kendall, North Moccasin and Barnes-King mines.——E. E. Wright has sold his one-quarter interest in the Boss fraction claim, adjoining the Bullard property, to R. Hamilton, of Kendall, for $1000.

Jefferson County.

General Manager M. L. Hewett of the Cataract C. M. Co. at Basin has increased the force at the Bullion mines. Recently a body of rich ore has been opened up. The concentrator will be completed and ready to operate by September 1.

Lewis and Clarke County.

The Spring Hill, owned by the Pittsburg & Montana Co., 4 miles south of Helena, has commenced shipping to the company smelter at Butte. The mine is working forty men, who have piled a large amount of ore on the dumps, and shipments will be large.——The East Helena smelter is running three stacks, with a capacity of 450 tons of ore per day, and are receiving more ore than they can handle. The ore supply is the largest for years, and indications are that it will increase, making it necessary to blow in another stack.——The Red Bird Co. is crosscutting at the 500-foot level and is sinking another 100 feet on its Copper Hill property at Austin.

Madison County.

The new cyanide plant at Rochester is nearly completed. Five 16-foot and four 26-foot steel tanks, and filterers for the same, are being placed in position, and all that remains to be done before starting the mill is putting in the electric lighting plant. The Watseka mill is claimed to be one of the most economical in the State, everything being done as near as possible with water. The new flume from the McClay - Murray springs is completed; it is 1½ miles long, and supplies more than enough water to operate the plant.

The Garnet Co., near Pony, are undecided whether to put in an electric power plant, a gas producer plant, or to obtain electric power from the Madison Canyon Power Co. A plant capable of furnishing 125 H. P. is required and work must be started before the weather becomes too cold to run water in an open ditch.——Work has been commenced on a 600-foot tunnel to develop the Mountain Cliff vein in Mineral hill, near Pony.

Silver Bow County.

The Supreme Court has reversed the decision of Judge Clancy of Butte in the case of E. Hickey, L. A. Hickey and J. M. Stewart against the Anaconda and Washoe companies, better known as the Nipper case, in which the lower court, after a memorable trial, held that certain veins of the Amalgamated Co.'s Anaconda and Washoe veins found their apex in the portion of the Nipper mine, owned by Heinze. The case is reversed on account of errors, largely attributed to the failure of Judge Clancy to admit certain evidence brought out on cross-examination of Stewart, one of the plaintiffs.

NEVADA.

Lincoln County.

The Searchlight M. & M. Co. have started their new 15 H. P. hoist at the mine at Searchlight. An 800-pound bucket will be used for hoisting the ores. Sinking is to be resumed from the bottom of the 300-foot shaft. A 3-stamp mill is being put in.——The Shoshone claims, 4 miles east of Searchlight, near Summit Springs, and owned by G. B. Smith and E. R. Bowman, has been bonded to O. B. Steen and Geo. Montgomery, who have started work.

Storey County.

When the pumps in the Ward shaft on the Comstock are put in they will have sufficient capacity, with the pumps in the C. & C. shaft, to unwater all the lower levels of the Comstock lode. At present the pumps are lifting 7,250,000 gallons of water a day, but their capacity will be 3,000,000 gallons more daily after the Ward shaft pumps are placed in operation. This will result in extensive workings of the lower levels.

Washoe County.

At Olinghouse, on the No. 2 mine, O. M. Pudor is preparing to sink to the 300-foot level. As yet no mine in the White Horse district has reached this depth, and if the sulphides hold out at that depth the permanency of the camp is assured. Large tunnels have been started in the Oro and in the Pritchett & Dahl group.

OREGON.

Baker County.

Good ore has been opened up in the Minnie McDowell claim, near Cable Cove, by E. Rawson and J. I. Sturgill. The ore is being sorted for shipment to the Sumpter smelter.——The Conner Creek placer mines, near Baker City, have been sold to a California syndicate represented by S. Adams. The property was owned principally by Union Pacific Railroad employes and was sold for $60,000. By the terms of the sale the new company agrees to spend $5000 in improvements this year. The mines will be worked by the cribbing process.——The Buckeye mine is being unwatered and sampled.——In Rye valley, 30 miles southeast of Baker City, the Gold Coin mine is being developed by a company recently organized in Pendleton. Preparations are being made to put in a 40-stamp mill, ten stamps of which it is expected will be dropping by September 1.

It is reported that a good strike has been made in the Morris property, Greenhorn district, owned by the Iowa-Oregon G. M. Co. of Webster City, Iowa.——W. J. J. Smith, one of the partners in ownership of the Salmon group, near Greenhorn, says he will urge putting in a compressor at the property when he returns to the Cincinnati office of the company. The crosscut tunnel is in 900 feet. Drifting is to be carried on with the machine drills, if they are authorized by the principal owners.

L. V. Swiggett, manager of the Golden Chariot group, in the Bear Gulch district, near Sumpter, states that the ledge for which they have been driving the crosscut has been cut.

Douglas County.

The Bohemia correspondent to the Telegram reports that on the Hiawatha claims, on the west slope of Fairview mountain, 450 feet of work has been done, and the management has again commenced operations for the summer. A 5-foot ledge is exposed. The property is owned by the Hiawatha M. Co. David Finn has charge. Much work will be done, and it is the intention of the management to put up a mill.——The Gold Hill & Bohemia M. Co. owns the Wall Street, adjoining the Vesuvius and Music mines. Over 600 feet of work has been done, exposing three veins.——The Judson Rock nine claims, on the western slope of Fairview mountain, are making a good showing as development proceeds. Over 1000 feet of work has been done on this property. ——The Syndicate group, owned by C. E. Lockwood and E. Jenks, adjoins the Noonday and Helena No. 1. There are seven claims in the group, and the development consists of four tunnels, several crosscuts and surface openings.——The Phœnix group of three claims contains a good ledge. E. Jenks is the owner, and the property is on Horse Heaven creek, south of the Riverside group.——J. B. Morgan owns two claims below the Riverside. He has a ledge 12 feet wide.——The Mineral King claims, owned by A. W. Zinicker, on Horse Heaven creek, is below the Riverside.——The Mayflower claims, on Horse Heaven creek, is owned by the Mayflower M. Co., W. P. Ely being the principal stockholder. This property is opened up by tunnels.——J. M. Peterson and J. Klucky, owning the Golden Star group, have over 400 feet of work done.——The Sweepstake eight claims, on the west slope of Fairview mountain, S. J. Brund owner, is opened by a 250-foot crosscut and 200 feet of drifting on the lead.——The Three Monte group, on the slope of Fairview mountain, is the property of A. Churchill, who has 250 feet of work done on the three claims.——The Knott property is developed by a 250-foot shaft.——G. Bohlman of Cottage Grove owns three claims on the west slope of Fairview mountain.——F. Mackentire is developing the Clay property.——J. B. King, on the White Iron and Black Bear claims, is driving a crosscut.——The Pittsburg claims, owned by W. H. Shane and F. Flesher, contains 800 feet of tunnel, the longest tunnel being 200 feet.

Grant County.

Recent work on the Wide Awake four claims, near Alamo, owned by L. Steinmetzer and Wm. Turner, has opened a good vein of free milling ore.

The placer mine on Canyon creek, 2 miles above Canyon City, owned by Dart, Yorgenson & Walker, is closed for the season, the final cleanup having been made.

Jackson County.

At the Oregon Belle mine, in the Forest Creek district, the crusher, stamps and concentrators are in place in the new mill and the plant will be in readiness for operation by Aug. 1.——At the Golden Standard property, near Jacksonville, P. S. Casey has men working. It is likely that a mill will be put in this fall or winter.

Josephine County.

The Grouse Mountain mine, on Mt. Baldy, 2 miles from Grants Pass, has been sold to L. P. Larson and C. Jasper of Spokane, Wash. Development is under the management of A. L. Smith. ——The Horace Greely mine, owned by E. E. Blalock and H. H. Howe of Golden, has been bonded to the Greenback M. & M. Co. for $15,000.

As a result of the returns on ore shipped from its Picket Creek property, the Oregon Timber, Mining & Development Co. has put in a mill and reduction plant near Grants Pass.

SOUTH DAKOTA.

Pennington County.

The machinery for the Montezuma property, at the head of Irish gulch near Rochford, is being hauled to the mine.——J. Hartgering has made the arrangements for work on the Bullion mill near Keystone. The process will be Chilian rollers and amalgamating tables, with Wilfley concentrators, and then cyaniding the concentrates. F. Beedle is in charge of the work.

UTAH.

Juab County

The Tintic King M. Co. has been formed to work the Manhattan and the Revenue lode claims, near Eureka. L. Hopper will have charge of the development. The officers of the company are W. R. Pike of Provo, president; L. Hopper, vice-president, and E. Pike, secretary and treasurer.——A water seam has been cut on the 500-foot level of the Uncle Sam mine, near Eureka, which will supply the mine, which has heretofore drawn on the mill for its supply of water. C. C. Griggs is superintendent.——The ore shipments from Tintic district for the week ending July 21 amounted to ninety-two carloads, and one carload of concentrates from the Uncle Sam mill. The producers were: Gemini, 6; Bullion Beck, 3; Centennial-Eureka, 45; Yankee Cons., 4; May Day, 1; Uncle Sam Cons., 2; Eagle and Blue Bell, 6; Swansea, 6; Eureka Hill (lease), 2; Grand Central, 6; Victoria, 4; Ajax, 5; Carisa, 1; Mammoth, 1.

Park County.

The hoist has been put in at the King Con. mine at Park City and sinking is to be resumed from the 800-foot level.

Salt Lake County.

Sampling has been finished at the Utah copper mine, at Bingham, and the report to the American Securities Co. is being made out. The third east drift is to be connected with the Ohio drift 100 feet below.——The Bingham West Dip Tunnel Co. intends to run a 4-mile tunnel from the Tooele side through the Oquirrh range, and drain the West Mountain district. It expects to develop some mineral on its own ground and also provide water for the irrigation of Tooele lands. Reports submitted at the recent meeting showed that the company was free from debt and work was progressing on the tunnel. The following officers were elected: F. M. Lyman, president; F. M. Lyman, Jr., vice-president; M. Pratt, treasurer and manager; F. M. Bishop, secretary.——The Copper Center tunnel of the Boston Con., at Bingham, has been cleaned out and work resumed driving it ahead.——The American S. & R. Co.'s new 3000-ton copper smelter, which will be built 10 miles north from the mouth of Bingham canyon, will be ready for operation next spring, according to Daniel Guggenheim, chairman of the executive committee of the smelting company. The smelter was made necessary by the increasing output of the Bingham mines. The Utah Copper and Boston Con. alone will furnish 1000 tons of ores and concentrates to the new plant. The contracts on the Cactus and other properties and the increasing tonnage from this camp will justify the smelter management in fixing the capacity of the new plant at 3000 tons daily. Six full sections of land, 6400 acres, have been acquired by the smelting company, near the springs north of Bingham, as a site for the new plant and there will be no farmers to raise complaints of damage from smoke.

Sevier County.

B. T. Ashby has made arrangements to work the Congress claims on Gold mountain, near Richfield.

Utah County.

T. E. Steele and R. R. Steele, who own the Steele property, will start work in American Fork canyon August 1. —— The new flume now under construction at the Wyoming mine is 480 feet long. This will give the mine two flumes through which to convey their sacked ore from the mine to the teamsters' station. —— Work is continuing on the Silver Glance, near the Steele group, under a lease held by J. H. Wooton.

WASHINGTON.

Ferry County.

Alex. Sharp, manager of the First Thought and Napoleon mines, near Orient, reports that the First Thought is shipping a carload of ore a day to the smelter, while the Napoleon is shipping eight carloads a week. These mines are owned by P. Burns.

Skamania County.

The McCoy Creek Mines Co. has been formed, with principal place of business at Chehalis, by L. J. Sticklin, G. E. Nolan, H. B. and B. J. Blankenship, A. Edlund and K. Anderson. The new district is near the northern boundary of Skamania county, on McCoy creek, a tributary of the Cispus, which in turn flows into the Cowlitz. The mines are reached by way of Chehalis. The company intends to put in a mill and begin active mining.

WYOMING.

Carbon County.

(Special Correspondence). — The mill at the Penn-Wyoming Copper Co., of Encampment, is handling all the tonnage the tramway can supply. The Hancock jig is a successful feature of the mill. The large

furnace is to be blown in soon. The Doane-Rambler Co. is about to build a concentrator. The camp has a healthy appearance and all available teams are hauling copper to Walcott.

Encampment, July 20.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Boundary District

The newly appointed officers of the Dominion Copper Co., which has taken over the holdings of the Montreal & Boston Co., have arrived at Phœnix and are making arrangements to resume work. These include M. M. Johnson, chief consulting engineer, T. W. Drummond, the local superintendent, and W. C. Thomas, the smelter superintendent. They intend to reopen the mines at once, also starting the company's 2-furnace smelter at Boundary Falls.——The shaft on the Prince Henry is down 65 feet.——The diamond drill which has been working with satisfactory results on the Wolford group in Wellington camp is being removed to the Jewel property in the Similkameen.

Nelson District.

The May Day and Pink Diamond claims, near Ymir, owned by J. F. Harbottle and others, have been bonded to John Boultbee of Rossland at $15,000.——Near Salmo, strikes have been made near the Queen and Kootenay Belle mines. Billings & Schwinkie made the first discovery, and J. G. Devlin of Nelson has located rich ground.——The Kootenay Belle mine, on which Patrick Clark recently relinquished his bond, has reverted to the former lessees, Bell Bros. of Salmo.——The 10-stamp mill at the Porto Rico mine, near Ymir, has been started by G. W. Barnhardt, the lessee. A large quantity of high grade ore has been broken down for milling. The mine is also being opened up on a deeper level.

Rossland District

The tonnage of ore shipped from and crushed at the Rossland mines for the week ending July 22 and for the year to date was as follows:

Mine	Week.	Year.
Le Roi	1,850	70,131
Le Roi (milled)	210	510
Center Star	2,250	53 880
War Eagle	1,230	36,870
Le Roi Two	60	4,402
Le Roi Two (milled)	....	4,830
White Bear	....	1,100
White Bear (milled)	....	3,920
Jumbo	300	5,529
Spitzee	60	4,479
Velvet-Portland	....	1,977
Gopher	....	60
Homestake	....	30
Lily May	30	60
Totals	5,990	187,778

On the ninth level of the Center Star a station has been cut and a hoisting engine put in to deepen the shaft for 200 feet below that level. The purpose is to develop another shoot which has been opened by a winze extending down from the ninth level for 190 feet. —— The Jumbo is being developed on the No. 1 and the intermediate levels.——The following are the shipments for the week ended July 15: Le Roi, 1950 tons; Le Roi (milled), 150 tons; Center Star, 2430 tons; War Eagle, 1350 tons; Le Roi No. 2, 60 tons; Jumbo, 200 tons; Spitzee, 120 tons. Total, 6260 tons, and for the year to date, 181,788 tons.

The Le Roi Co. shipped from the mine to Northport during June 8738 tons of ore, containing 3430 ounces of gold, 3200 ounces of silver and 163,600 pounds of copper. Estimated profit on this ore, after deducting cost of mining, smelting, realization and depreciation, $13,600. Expenditure on development work during the month, $10,000. Experimental concentration mill commenced running July 1.

CENTRAL AMERICA.

Panama.

According to a decree passed by the cabinet council of the Republic of Panama, on May 15, 1905, the Republic of Panama retains the right to all mines, of any kind whatsoever, within its limits, even should the vein or drift, etc., lie below the surface of private property. The owner of such property has the right only to the surface, and the subsoil belongs to the nation. However, the owners of land overlying mines which are ceded or leased by the Government have a right to remuneration for the use of the surface of their land by the concessionaire or prospector, as provided by law.

MEXICO.

Cedros Island.

The Esperanza M. Co. of Cedros Island expects to blow in the new smelter as soon as G. Brown, the manager of the company, arrives at the mines. This is the Morgan smelter, which was set up at San Diego two years ago, but never used. It was afterward bought by Mr. Brown and taken to Cedros Island, but has been but recently set up. The Esperanza Co. has been shipping copper ore to San Diego, where it has been reshipped to the smelter at Tacoma.

Guanajuato.

F. G. Corning, president of the Guanajuato Con. M. & M. Co. at Guanajuato, reports that the new cyanide plant is running successfully on a crude ore production ranging from 130 to 150 tons daily. This output it is expected to gradually increase to the full capacity of the plant, which is estimated at from 180 to 200 tons daily. The waste tailings from the process show from 50 cents to $1, United States currency, per ton The estimated differences, based on the assays of the mill headings and tailings, indicate a saving by the process as now in operation, with combined mechanical concentration and cyanidation, of 90% of the gold and silver values. This is an improvement, without increased cost, over the old milling process heretofore in use. The company's Sirena mine has many years of ore in sight. On the fifth level below the main tunnel, at a depth of 1200 feet from the surface outcrop of the vein, the ore bodies have developed widths of from 20 to 100 feet. The mine and mill are operated by electricity furnished by the Guanajuato Power & Electric Co.

Chihuahua.

R. B. Hutchinson, general manager of the Concheno mine, near Ocampo, states that his company has decided to increase the capacity of the present 60-ton cyanide plant at the mines to 100 tons daily. An electric power plant is also planned.

Jalisco.

The Mexican-Union M. Co., operating in the Ayutla district, is enlarging the 35-ton reduction plant at the Soquite Prieto mine to take care of increased production. This capacity will be doubled. W. H. Lees is manager.

Sonora.

A 10-stamp mill and cyanide plant is to be put up at the Anita mine of the Magdalena M. & M. Co. at Llano. ——The Yerkes G. M. Co. at Cajon de Amarillas, in the Altar district, is putting in an air compressor and machine drills.——A. H. Moore is developing a gold property, 20 miles southwest of Llano.——At Toledo the Yaqui River S. & R. Co. are putting in a new reverberatory furnace which will have a daily capacity of 100 tons of calcined ore or sixty tons of raw.——V. S. Oliver, manager of the Tucabe mine, in the Magdalena district, beyond the Santo Domingo river, has resumed operations. The 110-foot shaft will be sunk an additional 100 feet and 400 feet away a 3-compartment vertical shaft will be sunk.——J. R. Magruder has let a contract for sinking a new shaft upon the Yeso mine, near Las Cruces, and a new mill has been ordered for the property. It will have a daily capacity of thirty tons of ore and will be a dry crusher and chlorination process.

NORWAY.

The British consul reports regarding the Sulitjelma copper mines that 1400 men were employed and 80,000 tons of ore were produced in 1904. Of this amount about 64,000 tons of copper pyrites, containing 45% sulphur and 3⅜% to 4½% copper, were exported, and also 15,000 tons of ore for smelting. A wire rope tramway 4 miles long was built to the Jakobsbakken mine. Various other improvements have been effected, including a smelting house in which a new process is to be used. This process effects a saving in coke, and may be described as a direct application of the Bessemer process to the ore. ——The Alten Copper Works in Finmarken and the Krængenan mine have employed 360 men. Copper ore has been produced containing 390 tons of copper.——The Bossmo pyrites mine in Moi Ranen produced 26,100 tons of pyrites containing 49.5% or 50% sulphur, and employed 240 men.——The Roros Copper Works produced 18,000 tons smelting ore and 11,000 tons pyrites; 733 tons of copper were sold during the year; 600 men are employed. For 1905 a production of 800 tons of copper and 13,112 tons of export pyrites is planned.——The Killingdal mine, north of Roros, produced 14,000 tons pyrites and employed 100 men.——The Kjoli mine, near Roros, has built an aerial tramway 10 miles long.——The mining of iron pyrites, principally for export, has increased from 105,000 tons in 1900 to about 120,000 tons in 1904. Italian sulphur, which has hitherto been used in the Norwegian sulphite-cellulose factories, is now being replaced by Norwegian pyrites. Twelve or thirteen thousand tons of sulphur were formerly imported, but the factories now build roasting ovens for Norwegian fine pyrites, thereby saving about 5 kroners per ton of cellulose. When all the factories have carried out this plan the home consumption of pyrites is estimated to rise to 30,000 tons per year, as compared with 15,000 tons in 1904. The production of pyrites in 1905 is expected to rise to about 160,000 tons on account of the workings at Sulitjelma and Kjoli. Between 3000 and 3100 men were employed in 1904 in the Norwegian copper ore mines, and the gross value of the products, delivered at a Norwegian port, amounted to £264,000.

Commercial Paragraphs.

THE new plant of the Vulcan Iron Works, Toledo, Ohio, will cost $250,000.

WM. STEPHENS is erecting a 100-stamp mill for the Joshua Hendy Machine Works, of San Francisco, Cal., on the Alaska Perseverance mine, 4 miles from Redding, Cal.

ROY D. HUNTER, formerly manager of the Denver branch of the Sullivan Machinery Co., has been made general sales manager, with headquarters at the home office, Railway Exchange building, Chicago. W. P. J. Dinsmore succeeds Mr. Hunter as manager of the Denver office.

THE S. H. Supply Co., Denver, Colo., are furnishing two complete air compressing plants to Clear Creek, Colo., and Arizona. This company also reports sales of the Wild mill, which they are manufacturing, as follows: Two No. 2 mills to Idaho and No. 2 and No. 3 mills to Mexico.

AT the Lewis & Clark Exposition at Portland, Or., the Byron Jackson Machine Works, 411 Market St., San Francisco, Cal., has a working model of what is stated to be the largest high-head series centrifugal pump in the world, now in operation at Grants Pass, Or. The pump has a capacity of 10,000 gallons per minute, is designed for 500-foot lift and tested to a working pressure of 250 pounds. The model illustrates the method of creating artificial pressure at the nozzle, discharging through a giant against the bank of a miniature placer mine.

THE new Ingersoll-Rand Co., which was recently incorporated for $10,000,000, will open offices on the fourteenth floor of the Bowling Green Building, 11 Broadway, New York City, early in August. The main offices of the Ingersoll-Sergeant Co., for years in the Havemeyer Building at 26 Cortlandt Street, New York City, and the offices of the Rand Drill Co., at 128 Broadway, will be moved to the new location. By reason of the consolidation of these two important enterprises the Ingersoll-Rand Co. will start with a larger and more widely distributed patronage, and a greater manufacturing capacity in the combined plants, in the rock drill and air compressor business.

THE Pelton Water Wheel Co. of San Francisco and New York has a contract for a water wheel installation for D. J. Aguirre & Co. of Tepic, Mexico. The head available is 175 feet, the plant consists of two Pelton wheel units of 700 H. P. capacity each, direct connected to 300 revolutions per minute General Electric generators, also two Pelton wheel units for driving exciters. Sturgess oil type governors will be used. Pelton wheels are universally employed at the sugar plantation of Aguirre & Co., there being six wheels at present employed for driving heavy sugar rolls by means of direct connection, machine shops, electric lighting plant, etc. The company reports that their export trade has increased in the past year, and that they have made large shipments to Central and South America, Japan and the Straits Settlements.

Personal.

A. CROWN is manager Fannie Barret mine, near Alma, Colo.

R. C. GEMMEL has returned to Salt Lake City, Utah, from Mexico.

W. E. THORNE is manager Snowstorm Hydraulic Co., near Fairplay, Colo.

E. K. AUSTIN is general manager Yellow Mountain M. Co., near Ophir, Colo.

JAMES REAL is superintendent Suffolk M. Co.'s mine and mill at Ophir, Colo.

S. L. ROPES has been made superintendent Bald Butte mine, near Helena, Mont.

A. M. FRIEND of Marshalltown, Iowa, is in Colorado inspecting his mining properties.

F. M. PERKINS has taken the management Beztan mines, Huetama, Michoacan, Mexico.

J. WHITE has been appointed superintendent Ferris-Haggarty mine at Encampment, Wyo.

JAMES CUSICK of Lead, S. D., has been made superintendent Ethel mine, near Rochford, S. D.

G. A. TREADWELL of New York City has been inspecting mines in Yavapai county, Ariz.

CHAS. DOBLER takes charge as superintendent Fairview mine, Pappoose, Trinity county, Cal.

OLIVER ELDREDGE of Alma, Colo., is manager Ling and Wheeler mines near Montgomery, Colo.

W. E. CONNELLY has resigned as superintendent Ferris-Haggarty mine at Encampment, Wyo.

RICHARD LLOYD has been examining mines in the San Francisco mining district, Mohave county, Ariz.

T. E. SCHWARZ of Denver, Colo., has returned there from a trip to the London mine in Park county, Colo.

J. M. PHILIPS, superintendent Rincon mine, near Martinez, Ariz., has returned from a visit to Lodi, Cal.

FRANK CARNAHAN has been made manager Cia Metallurgica Mexicana at Sierra Mojado, Coahuila, Mexico.

J. A. KIRBY of Salt Lake City, Utah, has been chosen superintendent Montana-Tonopah mine at Tonopah, Nev.

MONT TONG has been appointed general manager St. Paul M. Co. in Green Lake mountain, near Georgetown, Colo.

NATHAN GREGG, SR., has returned to Denver, Colo., from an inspection of mining properties in Park county, Colo.

O. TROJENOWSKY of Wallace, Idaho, has charge of building a mill at Tin City, Cape Prince of Wales, Alaska.

H. E. LEES is superintendent Creede United M. Co.'s mines at Creede, Colo. L. H. Norton is mill superintendent.

J. C. GEORGE of Milwaukee, Wis., interested in the Snowstorm Hydraulic Co. at Fairplay, Colo., is at the property.

W. J. SHARWOOD of Berkeley, Cal., has gone to the cyanide department of the Homestake mine at Lead City, S. D.

C. A. BOHN has been appointed manager Santa Rosalia smelter of the Encinillas M. Co. at Santa Rosalia, Chihuahua, Mexico.

H. C. ARCHER has resigned as superintendent Rising Star mine of the Bully Hill M. & S. Co. at De Lamar, Shasta county, Cal.

W. C. OFF AND DR. S. B. PREVOST of Kansas City, Mo., are looking after mining interests in Summit county, Colo.

P. S. CAULDREY has been made manager Le Roi Two mine at Rossland, B. C., succeeding Ernest Levy, who has returned to London.

JOHN TREWEEKE has been appointed general superintendent Belle of Thunder Mountain and Sunnyside mines at Roosevelt, Idaho.

W. K. JEWETT of Colorado Springs, Colo., and R. M. Gummere of South Bethlehem, Pa., have been in Alma, Colo., looking after mining interests.

W. A. PRICHARD, late West Australian partner of Messrs. Bewick, Moreing & Co., has opened offices at 681-682 Salisbury House, London Wall, E. C., for practice as consulting mining engineer and metallurgist.

Books Received.

The practicing analyst will find a useful working manual in "Western Mill and Smelter Methods of Analysis," by P. H. Argall. It has been written as a laboratory handbook for the assayer and chemist and describes the methods of analysis in every day use in mills, smelters and cyanide plants. The contents include chapters on standard solutions, slag analysis, ores, coal and coke and daily work in the cyanide process, together with valuable hints on refinery and laboratory methods. The author has selected the methods in general use, those that have been standardized, as it were, by the titration of experience. His language is concise and to the point, facilitating rapid and accurate determination. The synopsis of cyanide methods is complete and practical. The book is not an indiscriminate collection of untried methods. It is less complete than the ordinary manual which usually presents many alternative methods. But the processes given have been refined by the tests of experience and will help the busy assayer. It is published by the Industrial Printing & Publishing Co. of Denver, Colo., and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price, $1.50.

The fourth bi-monthly bulletin of the American Institute of Mining Engineers contains a number of interesting papers on the manufacture of iron, including supplementary data by James Gayley on "The Application of the Dry-Air Blast to the Manufacture of Iron," discussions on the same paper by J. W. Richards and T. W. Robinson and a paper by J. P. Roe on "The Manufacture and Characteristics of Wrought Iron." A. H. Brooks writes on "The Outlook for Coal Mining in Alaska," giving a summary of investigated and reported occurrences. Geology is represented by W. P. Blake's paper on "Origin of Orbicular and Concretionary Structure" and Ed. Halse's paper on "The Occurrence of Pebbles, Concretions and Conglomerate in Metalliferous Veins." The former paper is based on the study of a white volcanic tufa from Tucson, Ariz; the latter is a description of the occurrence of a water-worn conglomerate in a gold-bearing vein in the Remedios district, Antioquia, Colombia, South America, which, the author argues, was formed in situ by the flow of water in the vein itself. J. F. Kemp describes "The Copper Deposits at San Jose, Tamaulipas, Mexico," a study of the contact effect of a diorite-porphyry-laccolith intrusive in a fine-grained, bluish limestone. T. H. Oxnam contributes a detailed statement of conditions, methods and costs in "Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico." The system of wet crushing, concentration and cyanidation has successfully replaced dry crushing, roasting and pan amalgamation. A. H. Bromley writes of "Tin Mining and Smelting at Santa Barbara, Mexico," and G. T. Wickes on "A Machine for Drawing Coke From Bee-Hive Ovens."

The working geologist's library receives a valuable addition in Arthur Lake's "Geology of Western Ore Deposits." The author introduces his subject by an exposition of general features of mining geology. This is logically presented and clear cut in statement, although at times more detail would give a better comprehension of conditions. Positive statements are frequent, which are valuable to the student if they are not subject to successful contradiction. He gives a practical account of the historical geology of the Rocky mountains that is intelligible to one ignorant of the fine points of paleontology. Igneous rocks are described briefly, the manner of vein formation is described in accordance with generally accepted standards, and includes a description of the principal ores of the useful metals. Little new material is introduced, but the author gives an intelligent resume of the results of geological mining research of the past decade. The results of his own painstaking work are more fully exemplified in accounts of the important mining districts of Colorado, as illustrating the principles outlined in the preceding chapters. This section is probably the most valuable in the book, for from it one gains in condensed form an understanding of Colorado's mineral occurrences. The author is undoubtedly well acquainted with this subject, somewhat of a contrast, it must be confessed, with regard to his statements concerning other examples of Western ore deposits. The Homestake mine of South Dakota is dismissed with twelve words in this section. The State of Arizona receives two pages of text. This may be excusable on account of lack of space, but not so the statement that "the Mother Lode extends from Mount Ophir, in Mariposa county, to Mokelumne Hill, in Calaveras county, or over 70 miles," utterly ignoring the fact of its occurrence in Amador county, which at present contains its largest producers. The occurrence of sandstone and serpentine with the cinnabar deposits of the Coast range is not specially mentioned, although many accessories are named. These misstatements were found only after a searching examination and may be regarded as a few flaws in what is, in the aggregate, a good specimen, well worth the careful attention of the mining man. It might better have been called "The Geology of Colorado Ore Deposits." A good feature of the book is the ample illustration from the author's pencil which accentuates the important geological principles. It is published by Kendrick Book & Stationery Co., Denver, Colo., and will be sent postpaid by the MINING AND SCIENTIFIC PRESS on receipt of $2.50.

Obituary.

EDWARD W. NASH, president of the American Smelting & Refining Co., died in Omaha, Neb., July 22, from the effects of a stroke of paralysis sustained May 22.

Trade Treatises.

Bulletin No. 55, of the Crocker-Wheeler Co. of Ampere, N. J., illustrates and describes small generators arranged for direct connection.

Haeseler "Axial Valve" hammers are depicted in construction and in use in Form 6 of the Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York City.

Aerial tramways are attractively pictured and detailed in a neat brochure from the Vulcan Iron Works of San Francisco, Cal. Both double and single-rope tramways are illustrated.

"Progressive West" is the title of a new magazine devoted to the development of the material resources of the western country. It is edited by Mrs. M. Garwood and is published at Reno, Nevada.

Latest Market Reports.

SAN FRANCISCO, July 28, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27 3/16d (standard ounce, 925 fine); New York, bar silver, 58⅝c, refined (1000 fine); San Francisco, 58⅜c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.12½; Lake, 1 to 3 casks, $15.12½@15.25; Electrolytic, 1 to 3 casks, $15.25; Casting, 1 to 3 casks, $14.50@14.75. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £67 15s spot per ton.

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.42½; San Francisco, $3.70, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £14 ℔ long ton.

SPELTER.—New York, $5.50; St. Louis, $5.18; London, £23 15s ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $32.95@33.15; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, ℔ lb., 35@37½c. London, £150 15s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 18.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.60; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3¼c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $23.00@$23.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ¼c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 12c; Hallett's, 13c; San Francisco, 1000-lb. lots, 11c; 300@500-lbs. 12c; 100-lb. lots, 13c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ℔ set; 14 oz., 40s., 9¾c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¾c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2¼@2¾c; powdered sulphur, 2½@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 64c; cs., 69c; raw, bbl., 62c; cs., 67c; Lucol oil, boiled, bbl., 56c; cs., 61c; raw-bbl., 54c; cs., 59c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

MOLYBDENUM.—Best, $2.75 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

URANIUM.—Oxide, ℔ lb., $3.50.

MERCURY.—Bichloride, ℔ lb., 77c.

TUNGSTEN.—Best, ℔ lb., $1.25.

PHOSPHORUS.—American, ℔ lb., 70c.

SODIUM.—Metal, ℔ lb., 50c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MAGNESIUM.—Pure, N. Y., $1.60.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JULY 14, 1905.

794,834.—PUMP PISTON—R. Addison, Pomona, Cal.
794,837.—ROASTING FURNACE—Anker, Watson & Evans, Los Angeles, Cal.
795,017.—STEAM MOTOR—F. S. Barkelew, Los Angeles, Cal.
794,918.—CHART CABINET—L. O. Bisang, S. F.
794,925.—GARMENT HOLDER—J. W. Cairns, San Mateo, Cal.
795,105.—FURNACE FEEDER—W. H. Curtis, Portland, Or.
794,928.—CONCENTRATOR—W. G. Dodd, S. F.
794,931.—WATER HEATER—M. Flatland, S. F.
795,112.—SAFETY ELEVATOR—R. H. Gaylord, Pasadena, Cal.
795,034.—DRUM—G. Harris, S. F.
794,797.—TOOL HOLDER—P. Hawkinson, Astoria, Or.
794,801.—HARVESTER—B. Holt, Stockton, Cal.
794,714.—ORE GRINDER—F. J. Hoyt, Redlands, Cal.
794,865.—SPIRIT LEVEL—P. Kaufmann, Portland, Or.
795,137.—SIGNAL SYSTEM—F. V. King, Winslow, Ariz.
794,871.—WHEEL ADHESION—R. Lowry, Seattle, Wash.
795,018.—BOOK HOLDER—W. Maguire, Bisbee, Ariz.
794,875.—SEWING MACHINE—R. H. Moore, S. F.
794,733.—RETAINING RING—M. C. Neuner, Los Angeles, Cal.
795,161.—GAS GENERATOR—J. J. Nix, Los Angeles, Cal.
795,162.—GATE—A. Noe, Tacoma, Wash.
795,231.—CAR COUPLING—F. H. Norwood, Pasadena, Cal.
794,883.—BASKET—M. L. Porter, Redding, Cal.
794,884.—FRUIT GATHERER—M. L. Porter, Redding, Cal.
794,948.—LUGGAGE CARRIER—J. J. Richard, Pasadena, Cal.
795 176.—FIRE APPARATUS—S. A. A. Stenberg, S. F.
794,958.—DREDGER BOX—C. M. Symonds, S. F.
794,950.—INDICATOR—C. H. Townsend, Berkeley, Cal.
794,963.—KNITTING MACHINE—G. D. Whitcomb, Glendora, Cal.
795,084.—DENTURE—L. L. White, Portland, Or.
794,706.—ENGINE BOILERS—T. M. Wilkins, Seattle, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

PNEUMATIC OPHTHALMIC-CHART CABINET.—No. 794,918. July 18, 1905. Louis O. Bisang, San Francisco, Cal. This invention relates to an apparatus especially designed for use in connection with optical practitioners. It consists of a polygonal drum turnable upon a shaft upon which it is carried and a pneumatically actuated device by which the drum may be advanced to expose its sides successively, said sides having characters marked thereon which are designed to test the condition of a patient's eye.

INDICATOR AND ADVERTISER.—No. 794,950. July 18, 1905 Chas. H. Townsend, Berkeley, Cal. This invention relates to a device comprising endless movable belts and a mechanism by which said belts are driven at different rates of speed. It is designed to provide a movable indicator with figures or characters which are successively presented for inspection, and in conjunction therewith a second movable belt adapted to carry advertising or other matter and which is moved in unison with the indicating belt. In conjunction with this is an alarm whenever the indicator is moved to call attention thereto. The device is especially useful in barbers' shops or other places where a line of customers may be waiting to indicate the next in turn. It consists of a plurality of belts, independent drums around which said belts pass, mechanism by which the belts are advanced and a front through which the characters of each are exposed; means for removing belts and drums, said means comprising slotted bearings in which the shafts of the drums are turnable, and elastic sections in the belts whereby said belts may be extended to allow the drum shafts to be lifted from their bearings.

GARMENT HOLDER.—No 794,925. July, 18, 1905. John W. Cairns, San Mateo, Cal. This invention relates to a holder, and especially to a device for holding cuffs, collars and other light articles of apparel and which also comprises a receptacle for collar buttons, studs and other things. Its object is to provide a simple, attractive, inexpensive and practical device of this character. The device comprises a tubular holder having means at one end for attachment to a support, said holder having one end partially closed whereby the interior of the holder is normally accessible and serves as a receptacle for collar buttons and the like, said holder having garment-supporting means on its periphery.

MINING AND SCIENTIFIC PRESS.

Whole No. 2350.—VOLUME XCI. Number 6. SAN FRANCISCO, CAL., SATURDAY, AUGUST 5, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Development of a Prospect.

The past two years has seen greater activity on the deserts of southern Nevada than before in many years. The rich strikes at Tonopah, Goldfield, Bullfrog and in other districts have attracted men of every nationality and every condition in life to the wastes of rocks and sand in that desert region. Many of these had little knowledge of mining, or none at all, when they first reached the region of the mines, but they went into the hills like their more experienced companions, and, trusting to luck, as the greater number of them did, located any reef of rocks which seemed more prominent than those of the immediate vicinity, or which showed the stain of iron oxides or copper carbonate.

The outcome of those chance locations resulted sometimes in discoveries of mineral wealth where more experienced miners would scarcely have looked, simply because the conditions were somewhat different from the ordinary.

In many instances these gold and silver-bearing veins are unlike those in other regions, being found almost wholly in volcanic rocks, such as rhyolite and andesitic rocks of various kinds. Mineral deposits found in these formations are wholly different in appearance from those occurring in slates and schists or other sedimentary rocks or in granite or greenstone. In these latter instances the distinguishing features of the outcrop are usually a defined vein of white or mineral-stained massive or ribbon-like quartz. In the volcanic rocks there are also defined veins, but usually the outcrop is on a zone of fracture, shearing and mineralization which gradually passes over to the normal country rock. There are many of these zones of fracture and mineralization in the desert region, but not all of them are valuable for their precious metal contents. Some contain only iron oxides, with little or no silver or gold. These worthless "blowouts," as they are sometimes called, look much the same as the most valuable of the mines discovered under similar conditions. It is merely a question of values, and these cannot always be determined without assay, as was the case at Tonopah.

When a find of one of these reefs is made by the prospector his first move is to pile up a heap of rocks which he dignifies by the term monument. In this he places a folded location notice, claiming all the law permits, and often more. The next step is usually the location of adjoining land, to take in the extensions of the original location.

He next proceeds to locate additional claims on all sides for "protection" against possible legal troubles later on, and to make sure that nothing is overlooked. Following these precautionary measures work is commenced at the most favorable spot on the group of claims, and strangely subsequent development usually justifies the initial judgment of the prospector—and this applies to experienced, as well as inexperienced men. It is rarely that there are more than two or three, or at most half a dozen, very valuable pay shoots in one small district, and some of the greatest mines of the Southwest are practically alone, isolated from all other mineral districts and locally limited in extent.

Almost universally the first machine placed on a mine is a windlass. Some of the greatest mines of the world in their prospective stage have been so equipped. In fact, where a shaft is required it is the only rational device for hoisting inexpensively from moderate depth. The simple windlass is often followed by a whim, in which horse power is usually employed. Shafts are not infrequently sunk 200 feet or more with a device of this kind, though where the mine promptly proves up well under development, a steam, electric or gas engine hoist is installed. It is not uncommon to see a modern hoisting plant going in on a mine not over 40 feet deep. The limitation is a depth of shaft which will be sufficient to afford reasonable security from the flying rocks when blasting. Occasionally such energy is shown in equipment that the hoist is in place and the headframe built and under roof when it is still necessary to cover the collar of the shaft with a bulkhead of timbers to keep the flying rocks from tearing holes through the roof of the shaft house.

The devices employed by miners in reducing the amount and cost of manual labor about a new mine are ingenious and interesting, and some of these have been previously illustrated. The engraving on page 90 is representative of the first stage in the development of a claim near Goldfield, Nev., which may in time become a noted mine. The greatness of a mine cannot always be predicted from the surface outcrop. Mines, generally speaking, are made, not found. It not infrequently requires years of active and expensive developments and metallurgical experiment before a mine can be considered great from a financial as well as a mechanical point of view.

The Champion-Providence Mine, Near Nevada City, Cal.

A Noted California Mine.

Mining, which for more than fifty years has been vigorously prosecuted in the region adjacent to Grass Valley and Nevada City, Nevada county, California, had done much for the industry in an educational way, as well as producing many millions of dollars in gold from the mines. Many of the mines of these districts have become noted through long years of continued prosperity. For years the Idaho mine at Grass Valley was a famous producer. It was eventually closed down, but it has recently been reopened, and there is promise that it will again become a producer. The history of the Idaho is practically that of a great many other mines of the district. Some of the most important properties have had many "ups and downs." A season of prosperity has at times been followed by one of adversity, but in most instances a mine which has at one time been a profitable producer has again become so when vigorously worked under competent management.

The Champion consolidation is one of the noted groups of mines near Nevada City. It comprises the Champion, Merrifield, Wyoming, Providence and Nevada City mines, besides a number of others. At present a portion of the property is tied up by litigation with the Home Co., the dispute involving some interesting points in the law of apex and extra-lateral rights. Although a considerable area of valuable ground is idle through this suit, the property is being vigorously worked in other portions of it. A long drift has been run from the Champion into the Nevada City, and a good vein of mill rock opened up, and in other places good ore is being mined. On the surface some tributers are mining the outcrop and gathering the float rock, hauling it to mill, and are said to be doing very well by the venture. The accompanying engraving illustrates the surface improvements. At the extreme right is the hoist building over the Merrifield shaft, which is down 1600 feet on the incline. The building adjoining it on the left is the chlorination works, not at present in operation. The next building is the shaft house of the Champion mine. This shaft, also an incline, is down 2400 feet. Near this hoist is the old mill of thirty stamps. Between these buildings is seen the pipe line, which crosses the creek on a bridge. At the farther end of the bridge is the hoist of the Providence mine, not shown in the engraving. The large building on the left of the picture is the new 40-stamp mill, and just above it, a little to the left, is the original Wyoming shaft. To the right of the mill is seen the mouth of the drain tunnel, which is in nearly 5000 feet, draining the Nevada City to a depth of several hundred feet. The present workings of the Nevada City are far below this level.

MINING AND SCIENTIFIC PRESS.

ESTABLISHED 1860.

Published Every Saturday at 330 Market Street, San Francisco, Cal.
Telephone, Davis 771.

THE recent placing of a 20% ad valorem duty on zinc imported into this country is giving substantial aid to zinc producers of the United States, the price of zinc ores having gone up materially since the ruling of Secretary Shaw went into effect.

THE publication of cost sheets of mining and metallurgical operations have a beneficial effect on those engaged in these industries, as they have a tendency to stimulate a friendly rivalry, to bring down the costs and to lessen extravagance in all departments. The segregation of accounts also affords an opportunity to locate excessive costs in the department where they occur should such exist.

THE Argentine Republic of South America, concerning which numerous inquiries have been made of late, is at present an agricultural and pastoral country, but it is said to possess great possibilities in mining in the Andes, which lie along its western border. As yet these mines are developed only to a small extent, but, with the rapid settlement of the country and the influx of American and European peoples, material progress in Argentina's mineral development may be expected.

THE strong tone of the base metal market speaks well for the mining industry in America generally. Copper, lead and spelter are each showing an upward tendency, and this in the face of increased production. The great industrial activity in this country and abroad absorbs the metal output as fast as it reaches the markets, and prices are not only maintained, but advance under the stimulus of strong demand. Tin has not been as high as at present in many years, but up to the present time the tin mines of the United States have not yet reached a point where they can take advantage of this condition.

Graft in Mine Equipment.

Mines are frequently equipped with expensive hoisting and metallurgical plants which are either wholly out of proportion with the available resources of the mine, or entirely unsuited to the treatment of the ore. Not uncommonly the owners and directors of mines and mining companies have little or no knowledge of the business of practical mining, and still less of metallurgical plants and their operation. Such men are likely to build a smelter on a dry ore mine, or put in a gold mill to treat lead carbonate ores because they carry gold. From necessity, where the directorate of a mining company realizes its lack of technical knowledge, they naturally turn to the consulting mining engineer for advice and assistance in preparing proper plans and specifications for a suitable mining and reduction plant. In this engineer they must have implicit confidence, or his services would not be sought, but unfortunately the history of some mining concerns proves that occasionally this confidence is misplaced, and that the "consulting engineer" employed is either grossly incompetent and inexperienced, or that he is a "grafter," and sometimes both. On the other hand, the engineer may be competent, but easily influenced, and, desirous of securing a retainer, lends himself to the plans of another, and recommends what he knows to be unsuited to the requirements of the case, or, at least, that which he is not sure will be entirely satisfactory, trusting to some future turn of fortune's wheel for an opportunity to set himself right—in other words, he embraces an opportunity to experiment at the expense of his client.

In the manufacture and installation of mining equipment there is often large profit, particularly where the plant is extensive and the competition is not too keen, and substantial proofs of the friendship existing between the manufacturer fortunate enough to secure a good fat contract and the engineer who advises the purchase may sometimes pass. This practice, not at all uncommon in other industrial lines, has resulted in its abuse by some.

Take as an instance a mining company owning a valuable property, the ore of which is not free milling, but which really requires considerable chemical and metallurgical knowledge on the part of the consulting engineer, who is called in in an advisory capacity, to determine just what sort of plant would be best suited to the reduction of this ore, assuming the ore to be a sulphide, with several bases, but carrying also good values in gold and silver. The engineer advises a stamp mill and an elaborate lixiviation plant. The specifications are elaborate, and set forth in detail each part of the machinery and specify certain makes of mechanical devices which may run up the cost unnecessarily. The investment required in this plant would be large, but the possible commissions coming to the engineer would help to sooth his conscience, even though the entire plant must later on be changed and remodeled at great expense to suit it to the treatment of the ore.

Such grafting cannot but prove injurious to legitimate mining. To avoid such results, the investors should know that their engineer is competent to advise them properly, for in all probability there would be just as much advantage to the engineer in advising a proper plant in the first place as in that which ultimately proves to be useless for the purpose for which it was intended. Many large plants, it would seem, are ordered on insufficient investigation as to their adaptability to the ore to be treated and to surrounding conditions.

In one instance, the purchasing agent of an Eastern corporation owning mines in the West made a request for bids on a plant of certain description. The engineer for the house assured the would-be purchaser that the plant proposed was not at all suited to the ore, but was told bluntly that it need not concern him in the least; that the company had decided to build a plant of that description, and if this house did not care to furnish it they would go to those less particular. As the machinery people were out for business, they took the contract and built the plant, but as had been said, it was not adapted to the ore and it stands idle to-day.

A CORONER'S JURY in Shasta county, Cal., found that a miner who was killed in the shaft of a mine came to his death through the carelessness and incompetency of the hoisting engineer, who was immediately discharged. It seems unfortunate that a human life should be sacrificed to make it apparent that the hoisting engineer was incompetent. It is certainly a part of the duty of the management of a mine to know that a man appointed to so important and responsible a position as that of hoisting engineer, particularly when he must handle men, is competent and experienced as an engineer of this class, and also reliable as a man. The temperament and disposition of a hoisting engineer is almost as important as his ability as engineer.

Rock Nomenclature.

The widely divergent opinions of those high in authority in geological science, and its several branches, often render a clear understanding of what is meant most difficult, if not impossible, to nontechnical readers, if not to the "Doctors" themselves. This is notably the case in rock nomenclature. It is well known that rocks of certain groups pass by gradual transition from one type to another, the addition or absence of certain minerals, conventionally determined as essential, making an important difference in the name. It is not infrequently possible to obtain from a single rock magma half a dozen or more distinct classes of rock, and yet, in the face of this knowledge, the confusion, already more than sufficient, is being increased by further hair-splitting determinations until rock nomenclature is becoming so thoroughly involved that it begins to look as though it would require the labors of an international congress of geologists and petrographical specialists to bring a semblance of order out of the existing chaotic condition. More than twelve years ago the late Dr. F. M. Endlich, a noted mineralogist and geologist, said that in a few years the microscope would cease to be employed as a means of rock determination, as by its use confusion became more confused, and that the transitions of rocks from one type to another, with which all students of microscopic petrography are familiar, would eventually result in rock classification falling back upon chemical analysis as a means of identification. It is scarcely probable that the prophesy of this eminent scientist will be realized, if for no other reason than the advantage the microscope affords in the study of rock structure. It is well known that certain rocks of nearly the same chemical composition present a very different physical appearance, and under the microscope this difference is accentuated in even a greater degree.

If rock classification and nomenclature could be simplified, instead of rendered more difficult, by the creation of new and previously unheard of varieties among rocks already commonly known by names sufficiently definite and comprehensive, it would be greatly appreciated by all concerned.

ENGINEERS are not infrequently called upon to undertake the designing and building of structures which call for innovations. When unusual constructive features are introduced in these structures there is always the feeling that possibly the novel construction is not all that the engineer believes it to be—and a test is demanded, to prove the correctness of the engineer's theory and to demonstrate that the structure is safe. Without doubt the testing of new structures, whether built on new lines or after ideas long in use, is necessary but, in numerous instances, these structures are tested to their destruction, being required to sustain loads or undergo strains which never are equaled or approximated in working practice. When dams, arches, or other structures are built, it is well to test them to a reasonable extent, but not infrequently these tests are carried far beyond the limit of safety, and usually these structures, built on proper lines, are sufficiently strong and would meet every requirement. Recently, a reinforced concrete structure, which was not designed nor required to carry any weight, was loaded with sand for the purpose of test and the entire structure collapsed. In Mexico a concrete viaduct, built in a series of arches, was likewise tested to its destruction. It would seem that tests to determine the real capacity of an edifice or structure, or even so simple a thing as a rope, a timber, or steel beam, might be applied without going beyond the limits of rational demands for security.

CONCENTRATES.

THE micas of commerce are muscovite and phlogophite, the former being of more common occurrence.

NICKEL AND COBALT usually occur together, and where one is found at least a trace of the other is almost sure to be found also.

THE only mineral mined for commercial purposes which contains titanium is rutile. Its principal use is in the manufacture of titanium oxide for coloring porcelain.

THE presence of metallic lead and alloys of lead, zinc, etc., in amalgam, will lead to the belief before retorting that the gold contents of the squeezed amalgam is much greater than it really is.

DANAITE is a cobalt-bearing mispickel. When exposed to natural oxidizing influences it usually becomes coated with a pink efflorescence of erythrite or "cobalt bloom," a hydrous cobalt arsenate.

RUNNING ropes may be guided around curves by placing alternately horizontal and vertical rollers, the latter being slightly tapered, the greatest diameter being at the top, to prevent the rope working upward.

LARGE rock breakers should be able to break rock from a maximum size to a stated smaller size with less expense than in a smaller machine of the same type. This is a principle which is applicable to nearly every class of ore reduction.

THE metals mostly used in steel hardening are chromium, molybdenum, nickel, titanium, tungsten, uranium and vanadium. Titanium is used only to a very limited extent, other metals having been found to give more satisfactory results.

MONAZITE is an anhydrous phosphate of the rare earth metals—cerium, lanthanum and didymium. It is mined chiefly for its thoria contents, being obtained from placers, both modern and ancient. It is obtained in the same manner as gold, by sluicing.

METALLIC gold, when in very fine grains, or thin sheets like gold leaf, is slightly soluble in a dilute solution of hyposulphite of soda. Metallic lead is not affected. A moderately warm solution of sodium hyposulphite is more active on most minerals than a boiling hot solution. Silver sulphide is not soluble in the hypo solution.

IT is impossible to estimate the value of an undeveloped mine by surveying the surface, though great mines usually carry certain distinctive features which characterize strong ore deposits everywhere. There are important exceptions, however, and valuable mines occasionally underlie a surface that conveys little idea of the value beneath.

GARNET is a name employed to denote a group of minerals which are closely related in both physical and chemical properties. They are rather complex in composition, being silicates of alumina, with varying amounts of lime, magnesia, iron, manganese, and other metallic oxides, to which are due the various colors. All garnets crystallize in the isometric system.

AN authority has placed the relative cost of the excavation by hand of the various materials as follows: Hard rock, 1.2 to 1.5; medium hard rock, 0.75 to 0.100; soft rock, 0.35 to 0.50; friable soils, 0.20 to 0.25; loose soils, 0.13 to 0.18. These figures may be referred to the cost of excavating any particular kind of ground, for the purpose of comparison, when any one is known.

FULLER'S EARTH resembles clay, but unlike most clays does not become plastic upon being moistened. It is used in fulling wool and in clarifying and deodorizing oils, etc. It may be considered as a clay containing just enough fine silica to destroy its plasticity, so that it crumbles to fine powder when mixed with water. Some siliceous rocks upon decomposition are converted to Fuller's earth.

THE sources of tungsten are the minerals scheelite, wolframite and hubnerite. Scheelite is the most readily reduced of these to metal or to an alloy with iron. This mineral is a tungstate of calcium. It is usually white or cream colored and noticeably heavy. The most abundant of the tungsten ores is wolframite, the tungstate of iron and manganese. Hubnerite is similar to wolframite, but contains more manganese.

THERE is a structural difference between slate and schist, though the chemical composition of these two varieties of rock may be similar. Slate breaks with a smooth cleavage, which may be due to either sedimentation or to pressure, or both. Schist does not split as readily nor as smoothly as slate, having a more wavy appearance. Slates are uniformly fine grained, and schists may be either fine or coarse in texture. Many confuse these terms. The same confusion exists between slate and shale. The structure of shale is due entirely to sedimentation, and not to pressure. Shale is not as firm as slate, easily disintegrating. It is found more abundantly in the later rocks. Shales have a laminated appearance, due to bedding, and on exposure usually break in small fragments. Shale is simply a consolidated fine clay or mud—it may graduate into slate. When the grains become coarser the rock graduates into sandstone, and when very coarse is called grit.

DIAMONDS have been found in a number of localities in the United States, viz., in Alabama, in Shelby county; in California, in Amador, El Dorado, Butte, Nevada, Trinity and Del Norte counties, and one diamond is reported from Tulare county; Indiana, in Brown and Morgan counties; Kentucky, Russell county; Michigan, Cass county, a diamond of 10⅞ carats; Ohio, Clermont county; Tennessee, Monroe, Roane, Lutterell and Union counties; Wisconsin, Pierce, Dane, Washington, Ozaukee, Waukesha (15⅛⅝ carats) and Racine counties.

A "KEEVE" is a circular tank or pan in which a separation of mineral is effected by the agitation of the pulp by rotating paddles or stirrers, which are actuated by a vertical shaft revolving in the pan, and by hammers or other devices automatically striking the side of the tub to produce a slight shock. Hammers are sometimes similarly employed to strike a box containing sulphurets shoveled from the concentrator box, the object being to cause the sulphurets to settle more solidly and the water rising to the surface of the box and flowing away, thus reducing the moisture.

ASSAY SLAGS are always brittle, and some are harder and more dense than others, but the object should always be to make a perfectly fluid slag which will permit the lead particles, reduced from the litharge to take up the particles of precious metals, and to accumulate in a button at the bottom of the crucible. The earthy and other impurities are driven into the slag. If the slag is not sufficiently fluid, this result cannot be accomplished. The proper amounts and kinds of fluxes must depend on the character or composition of the ore. Copper makes the lead button hard, and antimony, arsenic, tellurium, etc., make it brittle. The cause of lead adhering to the slag is that improper fluxes have been used or that the heat has been too low to properly fuse the charge.

WHERE the mortar or the anvil block on a concrete foundation cuts unevenly into the concrete, it has been found by experiment that if a plate of steel (boiler plate) be placed between the anvil block and the concrete, the plate extending 2 inches or more beyond the edge of the casting, this tendency to uneven wear is obviated to a great extent. Concrete mortar blocks and heavy anvil blocks between mortar bottoms and concrete have a tendency to increase the crushing capacity of the battery, but it also hastens the crystallization of the stamp stems, with consequent increased breakage. Instances are reported where this increased breakage was noticed as 3 to 1 against mortars resting on wooden blocks. This being the case, it is merely a question as to which is the more economical—increased crushing capacity or lessened expense for repairing the broken stems. This each mill man must figure out for himself under the conditions existing at his mill.

A PROPER smelting mixture would require a careful analysis of available fluxes, where the basis of the charge is as follows: Cu, 4.35%; SiO_2, 52%; CaO, 9.3%; MgO, 0.3%; S, 3.5%; Fe, 12.1%; Al_2O_3, 4.55%; Ag, 3.82 oz.; Au, .06 oz.; to smelt in a 36-inch round furnace. Should figure on a 35% silica slag for this work, and a copper bullion product. The furnace should put through about thirty tons in twenty-four hours of ore and fluxes; fuel consumption about 13% of charge with good coke. An ore such as described is not self-fluxing and would require the addition of lime and iron flux, the amounts depending upon analysis of these fluxes. In general this ore would require a charge approximating: 22% good iron oxide flux; 35% good lime flux; 43% ore as submitted. Such an ore would not pay to smelt in a 36-inch furnace, and making bullion product, but if sulphides could be obtained in the vicinity, that would stand a small working expense; it would be possible to make it pay on a 100-ton basis, provided fuel is not too expensive. In the case of a sulphide ore with fuel not over $15 per ton, the same furnace should smelt fifty tons of ore in twenty-four hours on a fuel consumption of 6% or 7% coke. For method of charge, figuring and general data, see "Modern Copper Smelting," by Peters, in chapter devoted to "The Chemistry of the Blast Furnace."

THERE are several of the so-called penetration devices for determining the quality of asphaltic cement or pavement, the most noted being Bowen's and Dow's. Bowen's apparatus consists of a needle of stated size and weight, the vertical movement of which is indicated on a dial, by a pointer. The needle is secured to a lever which is balanced by a counter-weight. The needle is lowered to the point of contact with the asphaltum when a clamp is released and the needle penetrates the asphalt for the period ore of second, and the amount of penetration is registered on the dial. The asphalt must have been kept at a temperature of 77° F. for half an hour before the test is applied. The Dow machine consists of a No. 2. sewing needle secured to the end of a brass rod, which is connected with a metal tube 0.4 inch diameter and 1.6 inch long. Mercury is poured into the open end of the tube in any desired amount from 30 to 300 grains. The rod, tube and needle are free to slide vertically in a frame and can be secured in any position by a clamp. This vertical movement of the instrument is registered by a pointer on a graduated dial. The material to be tested must be at the standard temperature—77° F. (25°C.)——and the unit of measurement is the distance, in hundredths of a centimeter, that the No. 2 needle will sink into the asphaltum pavement in five seconds, when weighted with 100 grains of mercury. This latter instrument is the standard of measurement employed by the Government since Jan. 1, 1899.

WHEN a large excess of lime is added to cyanide solutions it results in the formation of Ca (CN_2). Only sufficient lime should be employed to neutralize the acidity of the ore. If the use of lime does not produce the desired result, it would, perhaps, be better to treat the ore with fresh water to wash out a portion of the soluble sulphates, and then a smaller quantity of lime should suffice. Very few cyanide operators use caustic lime. It is the almost invariable practice to use slacked lime. It is a very difficult matter to determine the amount of calcium cyanide present in a solution. The amount of cyanogen present can be determined and also the amount of calcium present. The operator must then judge for himself the amount of calcium cyanide in the solution. It is impossible to have calcium carbonate present in an alkaline solution in appreciable amount for the reason that it is an insoluble salt. W. H. Virgoe says, in the Journal of the Chemical, Metallurgical and Mining Society of South Africa, that if the alkali be lime, one molecule of the zinc salt requires the presence of two molecules of lime, and the equations are probably therefore as follows: $1 = 2(Zn\ Cy_2\ 2KCy) + 4Ca(OH)_2 + 2Ag\ NO_3 = 2Zn\ Ca\ O_2 + 2Ag\ KCy_2 + 2KNO_3 + 2Ca\ Cy_2 + 4H_2O$. $2 = 2Ag\ NO_3 = 2Ca\ Cy_2 = Ag_2\ Ca\ Cy_4 + Ca(NO_3)_2$. This paper was published in full in the MINING AND SCIENTIFIC PRESS, Oct. 31 to Nov. 21, 1903, inclusive.

THE Homestake mine at Lead, South Dakota, occurs in pre-Cambrian rocks, of presumably Algonkian age. These rocks consist of a series of metamorphic sedimentaries—quartzite, mica schist, quartz schist, graphitic, garnetiferous and chloritic schists, phyllites, slates, etc., intruded by ancient basic dikes, now altered, for most part, to amphibolite schist, but which were evidently originally a type of rock similar to diabase, as the hornblende has been found, by study of microscopic slides, to be uralitic—that is, altered from augite, and not original hornblende. In these greenstone schists are found a variety of minerals, mostly of secondary origin. They include, according to J. D. Irving and S. F. Emmons, actinolite, plagioclase, secondary quartz, and orthoclase in subordinate amount, with zoisite, titanite, leucoxene, and calcite. More recent intrusions of acid rocks have taken place. These rocks are of two kinds, rhyolite and what is described as a trachytoid phonolite. These latter dikes and masses are closely associated with the ore bodies of the Homestake mine, and are thought by some to have resulted in enriching the ore deposits. It is known, however, that the schists were gold-bearing prior to the intrusion of these dikes, as not only large masses of the older rocks are gold-bearing where there is no porphyry, as in the De Smet mine, but the overlying conglomerate at the base of the Cambrian is gold-bearing, while it is known that the intruded acid dikes are not older than cretaceous.

THE most important rock-forming mineral is quartz. It occurs in many forms and under many guises, and its presence is not always readily detected, being sometimes found in microscopic grains. The next most important rock-forming mineral is feldspar, of which there are several varieties. Feldspar is particularly prevalent in eruptive rocks, in some kinds forming a very large percentage of the entire mass. The most important characteristics which distinguish feldspars are the presence or absence of potassium, soda and lime. Orthoclase feldspar is the characteristic feldspar of granite (potash feldspar) and is colorless, greenish white to pink. Sanidine is the distinguishing feldspar of trachyte and rocks of that class. It is similar to orthoclase, containing potash, but also some soda. It is usually glassy and transparent. In color it is grayish or yellowish. A third variety of potash feldspar is microcline, which occurs in irregular grains rather than in distinct crystals. There are two other varieties of feldspar, intermediate between the alkali orthoclase feldspars and the basic lime-soda feldspars. These are cryptoperthite (a soda-potash variety) and anorthoclase (a potash-soda variety). They are found mostly in basic rocks. The plagioclases are the several varieties of feldspar which range between the soda feldspar (albite) on one hand and anorthite (the lime feldspar) on the other. Oligoclase is next to albite, containing relatively much soda and a little lime. It weathers readily to kaolin and white mica. Andesite is a soda-lime feldspar, in which there is a relative increase of lime over that in oligoclase. It is the characteristic feldspar of the andesites and kindred rocks. Labradorite is a lime-soda feldspar and is found only in dark colored basic rocks, such as dolerite and norite. Anorthite is lime feldspar, and is the ultra basic feldspathic constituent of volcanic rocks. It is common in the lava of modern volcanoes.

Amalgamating Tables.

Written for the MINING AND SCIENTIFIC PRESS by ALGERNON DEL MAR.

The accompanying sketches represent three styles of amalgamating tables shown without the copper plates and without supports. Each copper is presumed to be 4 feet in length (although, for convenience in drawing, they are represented as 3 feet) and 4 feet 6 inches respectively in width, with a drop of an inch after each plate. A higher drop between the plates would have a scouring effect, while half an inch is often sufficient to secure the desired result—that of turning the pulp over so that any floating particles of gold or "quick" may be brought into contact with the amalgamated surface of the plate. Should the copper plates be 4 feet wide, as is often the case, the side strips C (Fig. 1) may be made 4 inches wide, instead of 1 inch, or an offset may be made at the top of the table to fit around the lip of the mortar. The

Method of Constructing Table.

objection to the 4-inch strip is that it takes off 6 inches of space between two tables, which in mills where the battery posts are narrow would inconvenience working between the plates.

Should it be deemed advisable to have the upper 4 feet of plate detachable, this can be easily arranged in each case; but, unless special care be taken to make a good joint and a sufficient overlap, the table will be very leaky.

There are three important essentials in an amalgamating table, leaving out of question the grade or angle of inclination: First, it must be strong and rigid, to bear heavy weights and strains; second, it must be water tight, to prevent loss of gold by leakages, and to prevent loss of temper on the part of the millman, who neither desires to see gold lost nor to wade about in rubbers; and, third, it must be level on a line normal to the pitch of the plate, or the pulp will go to one side. The center might even be a shade lower than the sides, for the tendency is always for the pulp to go to the sides.

Another important consideration, that has not so much to do with the construction of the table as of the mill, is that the floor on which the table rests, or, at least, on which the supports of the table rests, should be totally detached from the battery itself, for the vibration caused by the falling stamps, if communicated to the table, will cause amalgam and "quick" to gradually work down the plates, and it is most unpleasant for the millman who has to stand and work about on that same floor for twelve hours at a stretch. With the old light stamps the vibration was not an important consideration, but with stamps weighing from 1000 to 1300 pounds, dropping over 100 times a minute, it is an important matter and must be reckoned with as a primary factor in mill construction.

The table illustrated in Fig. 1 requires little skill to construct, and the amount of lumber required in each case being equal, it is, perhaps, to be preferred. There are many other types of table, but Figs. 1, 4 and 5 are representative and may serve those who are not altogether familiar with the subject in making a choice. Some prefer one piece of copper 12 feet long; therefore no transverse joints or steps are necessary; but strength and insurance from leakages are still the prime considerations.

The side strip, to be sure of a water-tight joint, may be bolted down with ¼-inch bolts or securely nailed or screwed, as is more often the case. The plates should be underlaid with blanketing or canvas, the latter preferred.

It is often a matter of discussion whether the top of the table should be made with tight-fitting boards or open spaces left between them. The writer is of the opinion that it makes little difference, if the side strips and all other joints are absolutely water tight. But can one be sure before actually turning on water? If there are leakages and the boards are planed to fit tight, any moisture getting under the plates will tend to warp the table and so buckle the plate. It is obvious, therefore, that leakages must not be allowed. A good plan is to plane the boards and leave about ⅛ inch space, between which fill with some material that will expand before the wood, such as oakum. Any liquid getting under the plates will then cause a water-tight joint without warping the boards.

At the end of the plates it is best to have a tail box (Fig. 3), the length of which equals the width of the table, and about 8 inches wide.

All the pulp from the table falls into the tail box, which is fitted with a discharge hole at or near the bottom, through which the pulp passes to the mercury trap (shown in Fig. 3) through a connecting pipe.

The exit of the pipe or pipes from the tail box into the trap should be about 2 inches above the bottom of the tail box, and the pipe should dip into and near the bottom of the trap and not discharge on the surface, for in this case the whole object of a trap is negatived; the essential feature of a trap is to create a zone of comparative quiet, where the heavy amalgam and "quick" may have a chance to separate from the lighter sand and sulphurets. An ordinary truncated pyramidal trap is shown, but there are many other patterns equally as good, some with baffle boards and some with floats.

The Bingham Mining District, Utah.

A work of practical as well as scientific interest is a professional paper entitled "Economic Geology of the Bingham Mining District, Utah," by J. M. Boutwell of the United States Geological Survey. An introductory chapter on the general geology of the region about the Oquirrh range, by S. F. Emmons, adds much to the value of the paper, and a section on the areal geology of the Bingham district, by A. Keith, contributes greatly to its interest.

The field work, of which this report represents the final results, was first undertaken in the summer of 1900. Owing to the fact that the geological structure of this district proved to be unexpectedly intricate, the work of investigation has been more prolonged than was at first expected. While the delay is cause for regret, this regret is much tempered by the consideration that, had the report been published earlier, many important facts brought to light during the vigorous development of the region in late years would not have been available.

In his introductory chapter, Mr. Emmons describes the general geological features of the Oquirrh range. The geography, topography and areal geology of the Bingham district are described by Mr. Keith. In the economic portion of the report, which forms the main body of the paper, Mr. Boutwell gives a history of the Bingham mining district, discusses the character, occurrence and genesis of its ores, and describes in detail the ore deposits in all the accessible workings of every property in the district. A chapter is devoted especially to the placer mines of the district. From all these detailed scientific and economic studies Mr. Boutwell deduces a valuable array of commercial applications, which will make interesting reading for the miner. The final chapter on recent developments brings the investigation down to date. The volume is amply and appropriately illustrated, with forty-nine photographic plates and ten miscellaneous maps, sketches and figures.

Bingham is the oldest and largest copper-producing camp in Utah. It is situated in the Oquirrh mountains, 20 miles southwest of Salt Lake City. The main slopes of the Oquirrhs, which rise steeply from elevations of 5000 feet on the surrounding deserts to elevations of 10,000 feet on the main divide, are deeply dissected by many narrow, steep-walled canyons. Toward the northern end of the range is a prominent canyon which follows a crescentic course northeastward across its eastern slope and receives several tributary canyons from the west. This is Bingham canyon, which has given its name to the mining district. Its drainage basin embraces the principal mining localities which constitute the Bingham district, an oblong area of about 24 square miles.

This region has been the center of a complex succession of geological activities, which have resulted in the deposition of valuable ore bodies. The sedimentary country rock has suffered extensive intrusion, intense fissuring and partial burial beneath a latite flow. The ore bodies are centered in the localities which have undergone the most intense intrusion and fissuring. Outside the limits of the comparatively small area that is characterized by the combined effects of these several activities, ore deposits have not been found.

The present output consists almost entirely of low-grade pyritous copper ore with comparatively small amounts of enriched high-grade black copper sulphide ore and of rich argentiferous lead ore. The immense bodies of copper ore occur as lenticular beds in metamorphosed limestone adjacent to intrusives and fissures. The rich argentiferous lead ores occur in strong northeast fissures.

The daily output of the camp is about 2000 tons, which is produced almost entirely by five great consolidated properties located upon a belt of metamorphosed limestone. In 1900 the district produced only a little over 100,000 tons of ore; in 1904 it is reported to have had an output of nearly 1,000,000 tons of copper ore alone. Its total output from 1874 to 1904 is valued at about $40,000,000.

The two points in Mr. Boutwell's paper which will be of most interest to the geologist and the miner respectively are his conclusions regarding the genesis of the ore deposits and the probable future of the district.

Mr. Boutwell holds, briefly, that between Carboniferous and late Tertiary time monzonitic intrusives invaded sediments in the Bingham area, metamorphosed them and introduced metallic elements which replaced marbleized limestone with pyritous copper sulphide. Later, heated aqueous solutions introduced additional metallic elements, such as copper, gold and sulphur. Silver-lead ore was deposited in the northeast-southwest fissures, mainly by filling, partly by replacement. Since this second period of mineralization, these original ores have been altered in their upper portions, by surface waters, to carbonates and dioxides, and relatively enriched in their underlying portions through replacement by black copper sulphide with additional gold and silver, probably as telluride.

Mr. Boutwell believes that geological indications and recent developments are favorable to the future of the mining industry in the district. They show it is reasonable to expect that new shoots of valuable copper-sulphide ore will be found in the great limestones in central localities, and that new lodes of rich argentiferous lead ore will be discovered in the composite country rock about the head of Bingham canyon, and in or adjacent to the calcareous-carbonaceous shale northwest of Bingham canyon and Carr Fork. Furthermore, recent mining developments have increased the known resources of two types of copper deposits, first by indicating that the values in the great copper shoots descend in depth, second by proving that the disseminated low-grade auriferous copper ores in the monzonite can be milled at a profit. These facts indicate a probable regular increase in the output in the immediate future and imply the continued prosperity of the mining industry of Bingham.

This valuable work will soon be ready for general distribution. It is listed as Professional Paper No. 38, and may be obtained, free of charge, on application to the director of the Geological Survey, Washington, D. C.

Vertical Shaft Sinking on the Witwatersrand, South Africa.

In discussing the paper of H. F. Roche in the Journal of Chemical, Metallurgical and Mining Society of South Africa on "Vertical Shaft Sinking on the Witwatersrand," J. Pedrini said:

Mr. Roche depicted an ideal method and gear for sinking vertical shafts in future. I agree with him that the steel headgear and the permanent hoisting engine should be erected, if possible, at once, time permitting.

The author recommends the tamping in of 20 or 30 feet of clay directly above the first set of bearers. That might answer where the shaft is in country rock from the surface, but I contend that the tamping in of clay behind the timber cannot be relied on, nor is it advisable where there is water and heavy pressure behind the timber. A good plan and method, in my opinion, for sinking through surface soil sand or heavy ground, is to sink the shaft 2 feet larger than the size required and timber temporarily, say 6x6 inches (ground permitting), until the solid formation is properly entered, and the first set of bearers set in position in deeply seated hitches in the bottom, the ground leveled all around, and the first set of the permanent timber resting on the bearers set in position and closely lagged, when the bottom set of the temporary timber could be removed if practicable, and the space behind the timber filled with 2 feet of concrete; the operation repeated to the surface. Should there be any water a drain pipe is put in through the concrete at the bottom and run into a tank fixed for the purpose, and thence baled or pumped to the surface. A concrete mixer should be erected near the collar of the shaft and a chute connected to send the concrete down the shaft, thus saving unnecessary handling. This plan, in my opinion, will keep all surface water entering the shaft and will provide a solid foundation for the collar set. The most important point is that it practically relieves all pressure behind the timber. It has also proved a success in other mining fields where running sand and water were encountered.

I cannot endorse Mr. Roche's opinion in carrying down a Cornish pump in conjunction with a sinking pump where sinking operations are in progress for many reasons. The size of the pump might prove too small or too large for the water encountered, hence the unnecessary cost involved. He says that the size of the pump would depend on the quantity of water and the surrounding conditions and data from the outcrop mines. I am of the opinion that might prove very misleading, and many instances could be quoted where deep level mines have a great deal more water to contend with the outcrops; in other cases the reverse.

When we consider the great depth of future shafts, the marvellous progress of electricity as a motive power in other branches of engineering, and the introduction of electrically driven high lift pumps working at a pressure from 600 to 700 pounds per square inch, corresponding to a vertical height of 1500 feet, a Cornish pumping plant beyond a depth of, say 500 feet, in my opinion, has passed the stage of practical economy.

As an illustration, suppose a shaft, say 3000 feet in depth, to be equipped with a 10-inch Cornish pumping plant. Before the water is delivered at the surface it requires to be lifted by stages ten times, requiring ten complete sets of pumping parts, five sets of balance bobs, and five stations cut for same; ten cisterns will also require to be cut, 10 inch delivery pipes, about 3000 feet of 10 to 12-inch pitch pine rods, plunger poles, etc., and other moving parts, making a total weight of, approximately, over 150 tons of reciprocating details, requiring same to be started and stopped, say five or six times a minute—the maximum speed that this class of pump could be driven with safety, on account of the great weight in motion limiting it, and stresses are soon overreached, causing breakdowns. Now in an up-to-date high lift pumping plant there are light weights, smaller parts, continuous motion, requiring a smaller delivery pipe, delivering the water to the surface in two stages instead of ten, giving at once the most flexible system, accommodating to any size instalment, no moving parts in or near the shaft, with less supervision and practically very little wear and tear. These modern pumping plants will prove themselves far more economical in working than a Cornish plant. I also recommend a compressor air-driven plant with reheater should be put down as a stand-by in case of a breakdown.

Shaft sinking and mining on these fields are the simplest in the world, and the same is true as regards ventilation. It is only a matter of equipment and other detail for the mines to be worked at the lowest cost possible. We have no heavy water to contend with except in a few isolated cases, no excessive hardness of rock and everything favorable for record shaft sinkings being made. In a comparatively dry shaft I prefer hand labor over machines, being 20% to 30% cheaper, but when water has to be considered, machines have the advantage over hand labor, and I prefer the larger size, viz., 3⅛ inches diameter, instead of the small size, 2½ inches, and the greater number you can put down the shaft, the quicker the ground drilled, consequently a better footage record at the end of the month.

I can endorse Mr. Carter's remarks in regard to efficiency and good workmanship in regard to shaft sinking. It is better to sacrifice a little speed and make sure that the work is done in a substantial manner to last the life of the mine with a minimum cost of repair. Proper bearers should be put in at about 80 feet interval and only the best of timber put in the shaft.

Continuing the discussion, L. Simson said: I judge that Mr. Roche has been somewhat misinformed in regard to the sinking of the Catlin or East shaft of the Jupiter Gold Mining Co., Ltd. The average monthly sinking in this shaft for twelve months from Feb. 1, 1898, the time when active sinking commenced, after dewatering in January, was 146.6 feet, and the greatest amount for any one month was 186 feet. Similar figures for the Howard or West shaft of the Simmer & Jack West, Ltd., from March 1, 1898, give an average of 145 feet, with 203 feet for the month of July as a maximum. From these figures it will be seen that 211 feet per month were never made.

The natives working during this period were not all "O.R C. Basutos," but a mixed lot, and not more than half were "excellent," while fully one-third were very poor. No contractors were ever employed, and changes of employes were frequently made. The rate of pay for miners and timbermen was £1 for an eight-hour shift, and a bonus for footages over 100 feet was distributed to all those who were deserving and directly connected with furthering the shaft sinking, a part being often given to employes who pushed along on breakdowns, repairs, etc. It is interesting to note here that as late as 1895 similar bonuses were given for hand-sinking footages over 40 feet, and this limit has been gradually raised.

Where the ground permitted, shaft timbers were not kept within 30 feet, but generally 60 feet or over from the bottom. The conditions under which the sinking was accomplished were not "perfect," and, with the exception of the fact that there was little trouble from water, the equipment did not approach the ideal laid down by Mr. Roche.

In regard to buckets versus skips, it is probable that skips have given greater safety in the past, but with our present experience there should be no danger from the use of buckets down to 3000 feet. When three buckets are used on one double-drum hoist, one beign in process of filling continuously in that spot in the shaft where the least shoveling is needed, quicker cleanups and less shoveling will be done in a large shaft than with skips. If the nature of the ground will permit the timbers being kept, say 60 feet or over from the blasting, more presentable shaft timbers will result than is the case with some shafts on these and other fields, where the use of skips has necessitated the timbers being kept close down and the bottom set cleated.

Mr. Bradford has drawn attention to the most excellent incline sinking done under Mr. Britten's management of the Wolhuter during 1902. Since that time at the New Kleinfontein east incline shaft, under Mr. Way's management, an average of 171.6 feet per month has, I understand, been made over a period of five months, with a maximum of 213½ feet for one month. But even this is eclipsed by the work done in July, 1898, under E. H. Garthwaite's management at the Nigel Deep, where a 14 by 17-foot incline shaft was sunk at the rate of 260 feet in a month, two Ingersoll-Sergeant 3½-inch drills being used. Besides the rock from the bottom, rock from the development of six drives and several winzes and raises were hoisted through the shaft during the month, and all this with a 7 by 12-foot double drum hoist, situated underground at the top of the incline.

PERFECTLY transparent quartz, colorless and without flaw, is valuable if occurring in good sized crystals or masses. A ball 5½ inches diameter, cut from a crystal discovered at the Green Mountain mine, Chili gulch, Calaveras county, Cal., is valued at $3000. Several crystals from the same deposit cut 7 inch spheres, but they were not without slight flaws. A 7-inch ball without imperfection would have a value about $30,000.

The Ore Deposits of Mount Lyell.*

NUMBER IV.—CONCLUDED.

Written by J. W. GREGORY.

The two main ore masses of the Mount Lyell field both occur where masses of the schists have been nipped in the re entering angles between great, hard blocks of conglomerate. The Mount Lyell mine has been developed in schist, which is bounded on the east by the Great Lyell Fault; to the south by the cross fault, which has thrown the Great Lyell Fault to the west; and it is bounded below by a thrust plane, which probably shifted the downward continuation of

Development of a New Strike on the Desert. (See Front Page.)

the Mount Lyell ore mass to the west, and left it isolated as the buried pyritic mass of the South Lyell mine.

If this explanation be correct there must be two parallel faults below the Mount Lyell ore body—one at a depth of 100 feet below the No. 8 level, which has brought the conglomerates against the schist; and another about 50 feet below the same level, which cut off the original continuation of the ore body, and threw it to the west. It is possible, however, that there is only one thrust plane, which was formed before the date of the deposition of the Mount Lyell ore mass. In that case the ascending solutions which deposited the ores rose through the schists opposite the Great Lyell Fault, in the South Lyell Co.'s lease; on reaching the level of the thrust plane the solutions were diverted eastward over the platform formed by the thrust plane, so that they kept along the band of crushed and shattered rocks in close proximity to the Great Fault.

The intense heat generated by the formation of the Great Lyell Fault caused any waters that came from below along it to rise as hot solutions, and like most plutonic or deep-seated waters they were probably alkaline in character. They no doubt carried in solution sulphates of iron and copper and some silver and gold. These solutions, nearing the surface, had their temperatures lowered, and were subject to lighter pressures; they therefore naturally precipitated their contents along their channels. Where the solutions rose along the simple fault lines in the schists, they produced the widespread fahlbands of mineralized schist. In other places, owing to the intersection of cross faults with the Great Lyell Fault, the rocks were completely shattered and fault fissures ran in all directions through blocks of rock; in these cases mineralizing solutions would permeate the rock, removing the original constituents, molecule by molecule, and, replacing them by pyrites, formed the great ore masses. Hence the chief pyritic masses occur in every case where the schists have been completely crushed and shattered by intercrossing faults; and it is only in such positions that we can anticipate the discovery of similar ore masses. It is to be regretted that the money spent in the thousands of feet of experimental drives at the Lyell field were not devoted to prospecting the places where the chief cross faults cross the Great Lyell Fault, and in tracing the course of this fault farther north and south from the Lyell field.

The contact theory of the Lyell ores cannot be dismissed without considering the relations between them and the great series of igneous rocks which lie to the west of them, both north and south of Queenstown. These igneous rocks are probably a pre-Silurian series. They cannot have been connected with the formation of the Mount Lyell ore, which must be regarded as due to tectonic and not to igneous action.

The possibility of the ores having been introduced in the form of vapors, instead of in solution, must also be considered. The metals were probably carried into the rocks in hot alkaline solutions, for the primary ores are sulphides. The gangue materials are quartz and barite, the latter of which may have been introduced as a soluble barium sulphydrite subse quently oxidized to barium sulphate, and thus precipitated. The materials must in any case have arisen as solutions, for there is a striking absence throughout the field of volatile materials that could have ascended in vapors. There is, for example, very little arsenic. The ordinary analyses of the ores show none of it. It occurs in very small quantities in the form of enargite in some of the fahlore enrichments of the Mount Lyell mine. I saw no arsenical pyrites in the ores, but Mr. Batchelor tells me there was some at the northwestern end of level No. 4 in the Mount Lyell mine. Arsenic is practically absent from the great ore masses, and is only present in the small secondary enrichments. Antimony is, of course, contained in the fahlore, and thus is present in the fahlore enrichments of the Mount Lyell mine. It also occurs in small amount in some of the fahlband ores. It is somewhat more widely distributed through the field than arsenic, but it is confined to the minerals that were last deposited. The presence of antimony is less evidence of the action of vapors than is that of arsenic. The microscope shows that the fahlore occurs as strings in cracks through the pyrites or in thin skins around pyrites. The fahlore may have been due to vapor, but this is not probable, as it was introduced almost simultaneously with the quartz, which is generally deposited from solution.

Of other volatile metals, there is neither bismuth nor mercury, and there are none of the minerals of the tourmaline or topaz group, which are produced by the action of boron vapors on various feldspars. The amount of zinc sulphide is much less than of galena.

There is, moreover, no evidence that the ore masses were deposited in cavities or fissures which contained free air or were reached by superficial waters. Had meteoric waters taken part in the formation of the ores we should expect the occurrence of chlorides and carbonates, which are absent except from the gossans. If the ores had been deposited in cavities we should expect the deposits would have been in layers, or, to use Posepny's term, they would be crustified. This "crustified" structure is well developed in the pyritic ores of Roros, in Sweden; but there is nothing of the sort shown at Mount Lyell. The lamination of the pyrites at one place on Bench No. 3 is a pseudomorphic relic of the beds replaced by pyrites, and not due to the deposition of the material, layer on layer, in a fissure. Some of the quartz of the gangue shows an irregular comb structure, but this quartz occurs in cracks in the pyrites.

Another argument against the deposition of the pyrites in a free space, or in contact with surface waters, is the absence of sulphates (except of barium), of carbonates and metallic oxides, except where the pyrites has been secondarily altered.

These features in the great pyritic masses of Mount Lyell and the remarkable scarcity of gangue, and the general uniformity of the ore, with the concentration of the precious metals on the foot wall side of the ore body, all support the view that the ores were formed by the replacement, molecule by molecule, of the pre-existing rocks. The pyrites was introduced in solutions, which permeated the country in places that had been cracked in all directions by complex earth movements.

The enrichment of the gold on the foot wall side of the deposit is an ordinary case of secondary concentration. It is due to the action of descending waters, which removed the valuable metals from the higher part of the pyritic mass as it was destroyed by denudation, and then re-deposited the metals, when the soluble salts were reduced, at a greater depth.

Sodium Cyanide in Practice.

Written for the MINING AND SCIENTIFIC PRESS.

For several years the material sold as potassium cyanide, and commonly supposed to contain 96% to 98% of that salt, has been known to be largely made up of sodium cyanide. In a large number of consignments examined at the port of New York, Dr. Russell found from 10% to 55% of sodium cyanide—and only two brands out of eighteen were free from sodium.

More recently sodium cyanide has been sold as such and rated at its equivalent in potassium cyanide. Thus a fairly pure article, on account of the lower atomic weight of sodium, would test "125% potassium cyanide" and was sold at a proportionately higher price than the 98%, as it was supposed to be correspondingly efficient. At this rate a saving of about one-fifth of the freight would be made by mining companies adopting the new cyanide. Tests made in London were said to show an even better extraction of gold by sodium cyanide than by its equivalent of potassium cyanide, to the extent of several per cent, so that 100 pounds of the 125% would extract as much gold as 132 to 135 pounds of the usual 98% double salt, and it was further alleged to be more free from sulphides.

Doubt has since been thrown on some of these conclusions by the experience of several plants in Nevada, which commenced to use sodium cyanide but after a short trial have abandoned it in favor of the mixed 98% salt, regardless of the higher freight on the latter.

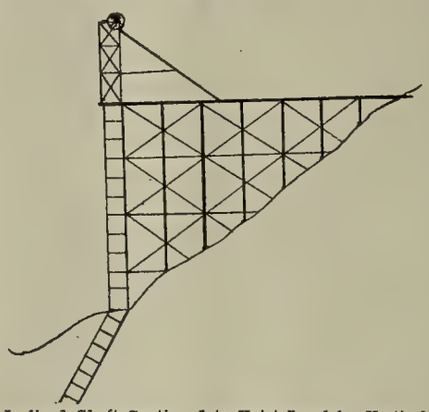
On the other hand, the sodium salt has been found the most advantageous at the Palmarejo mine, Chihuahua, Mexico. Incidentally it may be added that the consumption of cyanide at the mine mentioned is unusually high—averaging from 3 to 4 pounds of the 125% salt per ton of ore, the values being principally in silver. In a paper recently read before the American Institute of Mining Engineers, the manager, T. H. Oxnam, says:

"For over a year past we have been employing sodium cyanide exclusively. Titration with silver nitrate shows that the sodium cyanide being used is, on an average, equivalent to about 125% of potassium cyanide. Our experience at this place with sodium cyanide leads us to believe that it is fully as efficient as potassium cyanide for the dissolution of the values contained in the ore. It also appears that, since commencing the exclusive use of sodium cyanide, our solutions become rather less fouled than was previously the case. Freighting expenses are always a considerable item with us and by the adoption of sodium cyanide, equivalent, as above stated, to 125% of potassium cyanide, a saving of 20% of the freighting expenses on this article has been effected. Granted, as our experience seems to confirm, that sodium cyanide is equally as efficient as potassium cyanide, it would seem probable that it will gradually displace the latter, which, until recently, has been almost universally employed. Besides the direct saving in transportation expenses, the sodium cyanide appears to possess other advantages. From a metallurgical standpoint, other things being equal, it would seem preferable to use a salt as nearly pure as is to be obtained. Absolutely pure sodium cyanide being equivalent to about 132% of potassium cyanide, a product testing from 125% to 130% of potassium cyanide is manifestly nearly pure. It by no means follows, however, that the ordinary commercial cyanide, rated as 98% to 99% pure, and which by the usual silver nitrate titration will stand up to this strength, contains but 1% to 2% of impurities. That this commercial cyanide frequently carries a varying percentage of sodium cyanide is a well-known fact, and it of course naturally follows, on account of the relatively greater proportion of the CN radical contained in this salt as compared to potassium cyanide, that the greater this percentage of sodium cyanide contained in the ordinary 98% to 99% of potassium cyanide, the greater will be the percentage of impurities."

In view of these conflicting results, it is to be hoped that the managers of other plants, where sodium cyanide has been tried on a large scale, will follow Mr. Oxnam's example and publish the details of their experiences. From a chemical standpoint there seems to be no reason why a molecule of NaCN in dilute solution should act differently to a molecule of KCN, nor why the gold double cyanide of the one should be more or less stable than that of the other. Possibly the alkaline carbonate, present as an impurity in varying percentages, may have had some influence in the case of certain ores. Fuller information on the subject is certainly desirable.

Location of a Hoisting Plant.

Where the only suitable site for a hoisting plant is on the footwall side of a vein and on the hillside above the vein outcrop, which is near the bottom of the canyon, there is no mechanical objection to continuing the line of track upward on the surface to a proper landing, particularly if there be no material change in the angle of inclination. Inclined shafts not infrequently change their dip underground, and, if this be necessary, it may also be done on the surface, and would be an advantage over building a vertical line of timbers from the collar of the shaft to the desired height, as was done in the instance illustrated in the accompanying sketch. Here the out-



Inclined Shaft Continued to Hoist Level by Vertical Timbering.

Inclined Shaft Continued to Hoist on the Surface.

crop is near the bottom of a deep canyon and the only available site for the hoist was about 75 feet higher than the vein outcrop. The shaft was sunk at an angle of about 60°, and from the collar the shaft was carried upward vertically to a level with the hoisting engine by a frame work of timbers, as shown. By grading back of the hoist and at a somewhat higher level, the shaft could have been carried up on

the surface, somewhat after the style of that in the accompanying engraving, which is at the Adams iron mine in the Mesabi iron range of Minnesota. There are many places where surface inclines connect directly with shafts, and operations under such conditions are in no way unsatisfactory nor more expensive than where the entire shaft is underground.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

NUMBER II.

Written by T. H. Oxnam.

Experiments With Wet Crushing, Concentration and Raw Pan Amalgamation.—Shortly after my return to this property in March, 1901, at which time I assumed the management, a series of experiments was commenced to determine, if possible, a better method of ore reduction which would promise that future operations could be conducted on a financially successful basis—a condition which up to that time had not been attained.

In order to effect such a change, it did not necessarily follow that a higher percentage of extraction need be obtained. The difficulty might be solved by the adoption of a treatment whereby the quantity of ore treated would be substantially increased, while effecting at the same time a material reduction in the operating costs per ton, although the percentage of values recovered be no more, or might be even less, than that obtained under the old system.

With this object in view, two series of experiments were conducted; one, on the treatment of the different grades of ore by wet crushing and concentration, followed by raw pan amalgamation and subsequent reconcentration of the pan tailings; the other, on the treatment of the ore by wet crushing and concentration, followed by cyanide leaching of the resultant sands. Several very careful tests on a practical scale were made along the lines of the first set of experiments and, although the results indicated that, under such a system, operations could be conducted at a certain profit, they were by no means satisfactory and were not as promising as those obtained by the cyanide experiments.

A brief summary of some of the tests made are here given, and in them 1 ounce of silver is valued at $1.20 (Mex.) and $1 gold at $2 (Mex.).

Test No. 1.—Eighteen tons of ore, of as nearly an average composition as could be obtained of the ore being regularly treated in the mill, were crushed wet through a 30-mesh screen in a specially prepared battery. The pulp was passed over a Wilfley concentrating table, which removed 1 ton of concentrates; the tailings from the table were elevated by means of a belt and bucket elevator to a series of 3 connected settling tanks, having a combined capacity of approximately 50 tons. The overflow from the third tank was run to waste. After settling, the ore was transferred to the amalgamating pans in charges of 1.5 tons and the pans were run for from 6 to 8 hours at a speed of 68 revolutions per minute, the temperature of the charge being maintained at about 105° F. During the amalgamation, 200 pounds of quicksilver, 15 pounds of salt and 7 pounds of bluestone were added. The pans were discharged into settlers, from which the material was fed over a second Wilfley concentrating table, the tailings from which were run to waste.

The ore assayed 29.6 ounces of silver and $4.16 of gold per ton.

18 tons @ 29.6 oz. of silver = 532.80 oz. of silver = $639 36 (Mex.)
18 tons @ $4.16 of gold = $74.88 of gold = 149.76 (Mex.)

Total value of 18 tons of ore = $789.12 (Mex.)

First Concentration.—By first concentration 1 ton of concentrates was recovered assaying 126.93 ounces of silver and $17.40 of gold.

1 ton @ 126.93 oz. of silver = 126.93 oz. of silver = $152.31 (Mex.)
1 ton @ $17.40 of gold = $17.40 of gold = 34.80 (Mex.)

Total value of concentrates = $187.11 (Mex.)

The percentage of total values saved by first concentration was 23.70%.

Pan Amalgamation.—15.7 tons of material were worked in the pans, yielding 96 ounces of silver and no gold.

96 oz. of silver = $115.20 (Mex.)

The percentage of total values saved by pan amalgamation was 14.59%.

Second Concentration.—100 pounds of concentrates were saved by the second concentration assaying 117.15 ounces of silver and $19.24 of gold per ton.

1/20 ton @ 117.15 oz. of silver = 58.58 oz. of silver = $7.03 (Mex.)
1/20 ton @ $19.24 of gold = $0.96 of gold = 1.92 (Mex.)

Total value of concentrates = $8.95 (Mex.)

The percentage of total values saved by second concentration was 1.13%.

In this test there was a loss of 1.3 ton of slimes, equal to 7.22% of the total weight of ore taken. These slimes, which escaped in the overflow from the third settling tank, assayed 34.4 ounces of silver and $4.16 of gold per ton. The larger portion of these slimes could, however, have been caught in settling tanks of large capacity and treated, but the gain which would result from this source was considered as offsetting the losses that would occur in treating the concentrates.

The results of Test No. 1 were:

	Per Cent.
First concentration, total values saved	23.70
Raw pan amalgamation, total values saved	14 59
Second concentration, total values saved	1.13
Total, total values saved	39.42

Test No. 2.—A second test on 12 tons of this same ore, conducted along the same lines as Test No. 1, with but slight variations, gave the following results:

	Per Cent.
First concentration, total values saved	20.40
Raw pan amalgamation, total values saved	18.25
Second concentration, total values saved	2.72
Total, total values saved	41.37

Test No. 3.—The ore for Test No. 3 was taken from a large dump containing about 40,000 tons of material, which was of so low a grade that it was entirely worthless for treatment by the process used in the mill. Could a process be devised by which this material could be treated at a profit, either by itself or by mixing it with the regular mine ore, the dump would at once become a valuable asset, as there would be no mining costs to charge against it and it could be delivered at the mill bins for $1 per ton; 15.5 tons of this ore assaying 17.15 ounces of silver and $3 of gold per ton were taken and crushed wet through a 30-mesh screen. The crushed material was treated practically the same as in Tests No. 1 and No. 2, with the following results:

	Per Cent.
First concentration, total values saved	23.76
Raw pan amalgamation, total values saved	19.43
Second concentration, total values saved	1.63
Total, total values saved	44.82

The results of these tests could not be considered satisfactory, although a careful calculation of the working costs under this system showed that both the mine and the dump ore could be treated at a small profit.

Experiments With Cyaniding Mine and Dump Ores.—While the above mentioned experiments were in progress, extended tests were started on cyaniding mine and dump ores. The results did not indicate that a higher percentage of the silver content could be obtained than by the old process on the mine ore, yet they showed that the treatment of both mine and dump ores by wet crushing and concentration, followed by cyanidation of the resultant sands, should prove a commercial success. As a consequence of these experiments, I made a report in June, 1901, on the various tests which had been conducted, strongly recommending that the mill be converted into a wet crushing, concentrating and cyaniding plant. The report being favorably received, the old process was discontinued in October, 1901, and the conversion of the plant begun. The necessary changes in the mill to permit of wet crushing were effected, the cyanide plant was installed, and in February, 1902, operations under the changed conditions were commenced.

On account of the lack of sufficient fall between the batteries and the available location for the cyanide leaching vats, it was necessary that the material leaving the mill be elevated for a height of from 5 to 6 feet, and for this purpose a wooden elevator wheel built on the premises was installed.

The original idea was to subject the entire mill product to a proper classification by means of a series of steel hydraulic classifying cones, but owing to the lack of ample fall this idea was abandoned.

The experiments indicated that a thorough oxygenation of the sands during leaching was essential and the advisability of putting in a double treatment plant, in which half of the vats would be directly superimposed over the other half, was fully considered, but put aside, largely on account of the lack of proper fall, as well as on account of the greater initial cost of installation. This lack of fall between the mill and the cyanide plant rendered it necessary in several ways to construct the plant along rather different lines than would otherwise have been adopted.

Experiments on the ores crushed through 20, 30 and 40-mesh screens and leaching, after concentration, for varying periods of time, with cyanide solutions containing from 0.25 to 2% of KCN, resulted in the decision to commence operations, crushing through 20-mesh screens and subjecting the resulting sands to a ten-days' treatment with two strengths of cyanide solution, the weak solution to be approximately 0.5% of KCN and the strong solution to be approximately 1.5% of KCN; the ten-days' treatment to include filling and discharging and being equivalent to a nine days' leaching. It was the intention to send the mine and the dump ores to the mill in such proportions that the battery heads would average about 22 ounces of silver per ton.

Certain modifications of the method and alterations of the plant suggested themselves during the subsequent operations. The working strengths of both the weak and the strong solutions have been gradually reduced; and the transferral of as many charges as possible from one vat to another at some time during the treatment has been adopted. About two years ago the original leaching plant was increased by the addition of two leaching vats and, at the present time, two more leaching vats are in course of construction. The solution sump capacity has been increased and several other minor changes effected. Otherwise the leaching plant and the method of treatment have been altered but slightly since the commencement of operations under this system. Owing to ill health, I was obliged during May, 1902, to resign the management of this property, remaining, however, in the service of the company as their consulting engineer until May 1, 1903, and during this period making a visit to the property. On the latter date I again assumed the management. The present plant and practice is as follows:

Present System of Milling.—The ore averaging 6% of moisture is brought to the mill in trains of from 9 to 14 cars, each car holding 4.5 tons, and is dumped directly into the main upper storage bin, which has a capacity of approximately 1100 tons. From this bin the ore is drawn out over 3 5x10 feet iron grizzlies having 1.5 inch openings to the 7x10-inch Blake rock crushers. These crushers run at a speed of 250 revolutions per minute and the jaws are usually kept set sufficiently close to deliver a product which will pass through a 2-inch ring.

We have made extended tests on the using of iron crusher jaws cast in our own foundry compared with manganese steel castings, and have found the latter to cost slightly less per ton crushed and to give better satisfaction in every way. For some time past we have been employing the manganese steel castings exclusively.

The percentage of material falling through the grizzlies varies considerably according to the percentage of mine and dump ore being treated. Of the dump ore, which is very coarse and extremely hard, approximately 90% goes to the crushers; of the mine ore, which is much finer and of a softer nature, approximately 50% goes to the crushers, the other 10% and 50% respectively falling through the grizzlies. A secondary storage bin of approximately 1100 tons' capacity receives the ore from both grizzlies and crushers. The ore is then trammed to three small intermediate bins, each of about 50 tons' capacity. From here it is conveyed by means of half-ton cars to the hoppers of the Challenge ore feeders. This double handling of the ore is inconvenient, but is rendered necessary because of the construction of the mill which, as has been stated, was originally erected to conform to different requirements.

The stamps when equipped with new shoes weigh 850 pounds, distributed as follows: Stem, 350; tappet, 130; boss head, 215; shoe; 155; total, 850 pounds.

The stamps drop a distance of from 6 to 7 inches 100 times per minute, the order of drop being, 1, 3, 5, 2, 4; 20-mesh brass wire screens, No. 26 wire, are used and the height of discharge is kept as nearly as possible at 2 inches. The stamp duty is from 2.75 to 3.25 tons per 24 hours. The average stamp duty would doubtless be somewhat increased by the installation of narrow mortars of the Homestake pattern. The same wide, double discharge mortars used in dry crushing are still in service. The back discharge of these mortars has been closed by a blind screen, and cast iron liners have been introduced into the ends and backs of the mortars, thus reducing their inside measurements; liners for this purpose are cast here. For some time past forged steel shoes have been used in preference to the cast iron shoes of our own make. The steel shoes cost approximately 15 cents per ton of ore crushed as compared with approximately 18 cents for the cast iron shoes. We, however, cast all our own dies, for which purpose the worn out shoes and otherwise useless iron and steel scrap are employed. The average life of the forged steel shoes is about 95 days, while that of the cast iron dies is approximately 33 days. All of the cams are equipped with Blanton fasteners, which give good satisfaction. The camshafts are 4⅝ inches in diameter and weigh about 425 pounds. Heavier camshafts would be more preferable, but it would prove a difficult matter to bring in a camshaft of more than the present weight.

From the batteries, the pulp passes directly over ten Wilfley concentrators, running with a ⅞-inch stroke at a speed of 215 strokes per minute. During the year ending July 1, 1904, the concentrators removed 0.76% by weight of the ore forming concentrates, which contained 18.28% of the gold and 17.98% of the silver values of the ore crushed during this period.

A large wooden launder conveys the pulp from the tables to the tailings elevator wheel. The latter is 14 feet in diameter and is of the outside bucket type, having 22 steel buckets, each 18 inches long, 8.5 inches wide and 8.5 inches deep, with a total capacity of about 1025 cubic inches. The wheel is driven by a ⅝-inch plow steel wire cable, at a speed of 18 revolutions per minute. The discharge efficiency, as in all wheels of this type, is not high, the discharged tailings leaving the wheel in a launder 5.5 feet above the level of the mill launder supplying the pulp.

A large masonry sand retaining tank divided into four compartments, each compartment measuring 25x80x4 feet in depth, receives the product from the wheel. Distribution is effected by means of a central launder in each compartment, provided with a number of 4-inch side discharge pipes. Each compartment is provided with a removable end discharge gate, 4 feet wide, composed of pieces of 2-inch plank, planed smooth on the edges and sliding in guides secured to the side posts. As the compartment fills up with

*Trans. Amer. Inst. Min. Engrs.

sands the discharge of these gates is raised. The discharge overflow empties into the main slime launder. Each compartment also communicates with its immediate neighbors by means of small, side discharge doors. The purpose of this arrangement is that the mill product may be emptying into one compartment, from which a portion of the finer material escapes through one of the side gates to an adjoining compartment, while the finest material is passing off in the discharge over the lowered end gate of this second compartment.

It is found, however, that a considerable quantity of the finest material will always tend to collect at the lower end of the first compartment, receiving the discharge of the elevator wheel, to lessen which an overflow from the end gate of the compartment is also necessary. In every case, however, the first 5 or 6 tons of material removed from the compartments are always extremely slimy and are trammed a short distance to an open drying patio, where they are spread out, sun dried and broken up, after which they are mixed in with the coarser sands and treated in the leaching vats. A third compartment of the sands retaining tank is kept full of sands, which are being allowed to drain, while the dry sands are being trammed from the fourth compartment. Each of these compartments holds the sands of from 48 to 60 hours' crushing in the mill when operating under normal conditions. The retained sands are usually subjected to about 2 days' draining before commencing to charge them into the leaching vats. The very fine material escaping in the overflow from the masonry retaining tank is carried by means of a wooden launder to three, so-called, slime pits having an aggregate capacity of approximately 15,000 tons. Every precaution is exercised that no slimes escape at the overflow gates of these pits, but, as is to be expected, at no time is such overflow perfectly clear and free from suspended matter.

During the 18 months ending December 31, 1904, of the total net tonnage crushed in the mill, 19.16% went to the slime pits. Various sizing tests, using the ordinary brass wire assayer screens, have shown that on an average about 6% of this material is retained on 100-mesh, while approximately 85% passes a 200-mesh screen.

Although this material as a whole is chiefly slimes, which on long drying crack up into layers almost absolutely impervious to leaching, it is found that considerable quantities of extremely fine, but leachable, sands are deposited at the heads of the slime pits in the vicinity of the discharges from the slime launder. About two months after ceasing to discharge into any one slime pit, this very fine sandy material at the heads of the pits will have dried sufficiently during ordinarily dry weather to permit of being walked on, and it is then conveyed by contract labor to the open drying floor or patio, together with a certain percentage of more slimy material which unavoidably becomes mixed with it. Here the material is spread out, sun dried and thoroughly broken up, after which it is mixed in with the ordinary sands and treated by leaching.

During the past year 2400 tons of very fine material from the slime pits have been treated in this manner. By far the greater portion of the material collected in the slime pits, however, is so extremely fine and of such a clayey nature that, as above stated, it is almost absolutely impervious to leaching.

(TO BE CONTINUED.)

THE PROSPECTOR.

It is not always possible to tell from the hand sample the correct name of a decomposed rock. It is often necessary to study the occurrence in the field to get a knowledge of its structural relations. For instance, a mud shale may be transformed into a hard, dense, flinty jasper. Fine grained limestone may be silicified to a dense jaspery rock, and rhyolite or felsite, as well as other rocks, may be altered by silicification to dense jaspery rock. Each of these siliceous rocks bear a resemblance to the others, and if the occurrence can not be observed in place, the only thing possible toward identification is to simply call such rocks jasper, chert, flint or hornstone, etc. Rocks are often much decomposed from atmospheric or chemical agencies, due to more or less crushing and the infiltration of waters which oxidize and decompose certain mineral constituents, often removing some minerals and substituting others, as in the case of the silicification above referred to. Feldspars are altered to kaolin or clay-like minerals, calcium carbonate is found segregated, and the bisilicates—hornblende, augite, etc.—are altered beyond recognition to other minerals. So while it may be possible for this department to describe the rock sample as it now appears, it may be impossible to determine accurately, or perhaps at all, what the rock was originally The rock samples from Goldfield, Nev., are of this kind, and the following determinations are made as nearly as the small size of the specimens and their condition will admit. No. 1 is a silicified rock. It is marked "dike," but there is no evidence in the sample to indicate whether it is a dike or a portion of a larger formation that has been silicified along a certain zone. No. 2 is much changed, the feldspars being altered to clay. A rock so thoroughly decomposed as this which does not effervesce with acids suggests that the rock did not originally contain lime-soda, or soda-lime feldspars, and that the feldspar was largely orthoclase. The occurrence of blebs of quartz in the rock further suggests either rhyolite or quartz porphyry. The slickensides and tendency of the rock to cleave into flat sheets indicates that it has been subjected to pressure and movement, and the occurrence of pyrite indicates proximity to a vein or ore body. No. 3 has also been subjected to pressure and movement, and is apparently an altered rhyolite. No. 4 also looks like an altered rhyolite. It contains considerable iron oxide, and may be from the outcrop of an ore body, but whether low grade or not is for the owner to determine. No. 5 is similar to No. 1, though containing more iron oxide. A few small feldspars are seen, and also small plates of muscovite mica. No. 6 is a cavernous fine grained feldspathic rock, not greatly unlike Nos. 1 and 5. The color is due to iron oxide. It may also have been rhyolite. No. 7 is so thoroughly decomposed as to render identification impossible. It resembles No. 2 somewhat, but contains no pyrite. The feldspars have been wholly altered to clay. The rock is less siliceous than those previously described. No. 8 is basalt. It contains no olivine that can be seen without a microscope, and it is vesicular.

The samples from Denio, Or., have been identified as follows: No. 1, pitchstone, a variety of volcanic glass occurring in dikes, boses and beds, sometimes of great thickness. No. 2 is quartz, carrying a large percentage of micaceous iron (hematite); the yellowish mineral is epidote, and quartz, stained with dust-like inclusions of epidote. No. 3 is diabase, a basic intrusive rock. No. 4 is rhyolite, in which there is a large development of sanidine. No. 5 is a basic eruptive—olivine diabase. No. 6 is a fine granular quartz rock in which there is some disseminated pyrite. The yellow spots are iron oxide, due to the decomposition of some iron-bearing mineral, the nature of which is unknown. No. 7 is quartz in which the green material is chlorite intermingled with the quartz, and the greenish-yellow mineral is epidote, derived from decomposition of the chlorite. No. 8 is similar to No. 7, except for the absence of the chlorite and the presence of a large amount of epidote. There are no sedimentary rocks in the samples sent.

The specimens from Homestead, Or., are: No. 1, granular quartz with finely disseminated sulphide of iron (pyrite). No. 2 is baryta (barium sulphate), also called heavy spar. The green mineral is copper ore. The rock also contains a crystal of copper-iron sulphide altering to bornite. No. 3 is an altered igneous rock, diorite or granite, in which there are veinlets of quartz. The entire rock is siliceous and may be gold-bearing. The greenish color is due to chlorite altered from hornblende. No. 4 is greenstone, probably diabase. No. 5 is an altered rock (probably igneous), but is now mostly fine granular quartz and iron sulphide.

The three samples from Confidence, Cal., are: No. 1 a cherty quartz, containing a large amount of iron oxide (hematite) and probably some gold also. No. 2 is quartz, with scales of molybdenite (sulphide of molybdenum). This mineral when cleanly concentrated is worth about $200 per ton. No. 3 is decayed hornblende schist, probably altered from granodiorite. It is stained slightly with green copper carbonate (malachite) on one side. The brown mineral is iron oxide.

The rock specimens from Columbia mountain, Nevada, are found on examination to be much altered. The dark colored ore is almost wholly brown and red (hematite) iron ore. The bright, transparent and white crystals are calcium carbonate. The black portion is not manganese, but iron, and gives a red streak. This character of ore is sometimes called by miners "liver-colored" rock. The small, solid brown piece is similar to the other dark ore, but is more siliceous. There is no tungsten present in any of the samples. Gold and silver probably occur. The white, fine-grained piece is a much altered rhyolite. The darker, bluish colored piece is also a much altered eruptive, too much changed to make identification positive. It looks like a fragmental andesite—tuff. The gray rock that gives a red streak on striking with a pick is also tuff. The red streak is due to the presence of innumerable grains of red iron ore, which, on being scratched, shows the characteristic color of hematite. The alkaline taste of the samples is due to mineral salts present, owing to decomposition of the rock.

The mineral specimens from Landore, Idaho, are: No. 1, quartz, with needles of tremolite (a variety of hornblende). The dark color is due to a mat of fine hornblende crystals. No. 2 is a granular quartz rock, seemingly altered from a dike. It contains considerable iron sulphide (pyrite). No. 3 is a much altered feldspathic rock, the feldspar having been almost wholly altered to kaolin. It contains a small amount of iron sulphide. No. 4 is a fine-grained dike rock containing disseminated iron and arsenical sulphide. No. 2 and No. 4 may contain gold and silver, and possibly No. 3 also.

The red rock sample from Canyon City, Colo., is principally iron oxide. It resembles some scoriaceous lavas.

The Amended Location Notice.

Recently several readers have requested information on the amendment of mining locations. The frequent necessity for the amendment of mining locations has been anticipated by several of the mining States and legislation passed directing how it shall be done. The States which have made provision for changes of boundaries of mining claims are: Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, North Dakota, South Dakota, Washington and Wyoming. In all of the States, excepting Arizona, the laws are similar to those of Colorado, which are as follows: "If at any time the locator of any mining claim heretofore or hereafter located, or his assigns, shall apprehend that his original certificate (of location) was erroneous, defective, or that the requirements of the law had not been complied with, before filing, or shall be desirous of changing his surface boundaries, or taking in any part of an overlapping claim which has been abandoned, or in case the original certificate was made prior to the passage of this law, and he shall be desirous of securing the benefits of this act, such locator, or his assigns, may file an additional certificate, subject to the provisions of this act; provided, that such location does not interfere with existing rights of others at the time of such relocation, and no such relocation, or other record thereof, shall preclude the claimant, or claimants, from proving any such title, or titles, as he, or they, may have held under previous location."

The law in Arizona differs somewhat from that of the other States and reads as follows:

"Location notices may be amended at any time and the monuments changed to correspond with the amended location; provided, that no change shall be made that will interfere with the rights of others."

Concerning the amended location the Supreme Court of Colorado has said: "The evident intent of the statute is that the additional certificate shall operate to cure defects in the original, and thereby put the locator, where no other rights have intervened, in the same position that he would have occupied if no such defect had occurred. Such intent is in accord with the principle of all curative provisions of law."

Another court decision says: "Every one who is at all familiar with mining locations knows that in practice the first record must usually, if not always, be imperfect. Recognizing these difficulties, it has never been the policy of the law to void a location for defects in the record, but rather to give the locator an opportunity to correct his record, whenever defects may be found in it. * * * This is the function and proper office of amendments: To put the original in as perfect condition as if it had been complete in the first instance."

In making an amended location the following form may be used:

KNOW ALL MEN BY THESE PRESENTS: That I, ..., the undersigned, being a citizen of the United States, claim by right of amendment and relocation ..... feet linear and horizontal measurement on the ..... (naming it) lode, along the vein thereof, with all its dips, variations and angles, together with ..... feet in width on each side of the middle of said vein at the surface, and all veins, lodes, ledges and surface ground within the lines of this amended and relocated claim; ..... feet on said lode running in a ..... direction from the center of the discovery shaft of the claim originally located as the ..... (naming it) claim, and ..... feet running in a ..... direction from said center of discovery shaft. This amended additional and relocated lode mining claim is bounded and described as follows, to wit: Beginning at corner No. 1 (described by metes and bounds), being situate in the ..... mining district, county of ....., State of .....

That this is intended as an amendment and relocation of the ..... (naming it) claim, of which I am the owner, the location certificate of which is filed in Book ....., page ....., in the office of the recorder of ..... county. This amended and additional location is made for the purpose of changing the surface boundaries of said ..... (naming it) claim, so as to include within it the ground heretofore covered by the ..... (naming it) claim, also owned by me, the location certificate of which is filed in Book ....., page ....., in the office of the recorder of ..... county, and to secure all abandoned overlapping claims.

That this amended and additional location as above described embraces the original discovery, as well as all development work, which I or my predecessors in interest have performed upon or for the benefit of said original ..... (naming it) mining claim, and I therefore claim that this amended certificate of location relates back to the date of the original location of said ..... (naming it) claim, and that it is entitled to the benefit of the original discovery, as well as of all work done or improvements made by me or by my predecessors in interest within the limits of this amended and additional location.

This amended and additional certificate is filed without waiver of any previous rights. Date of original location of ..... (naming it) mining claim ..... Date of amendment and relocation .....

Signed ....

Dated ..... 1905.

Notes on Hydraulic Mining.*

Written by R. L. Grider.

The methods of working gravel deposits by hydraulic processes vary with the character and elevation of the material. If the deposits are heavy the giants must be placed behind the materials to be moved, in order to attain a direct drive and to utilize as much of the power as possible. However, if the materials are light the draw method may be adopted. In a placer mine on the Klamath river, California, in which the bedrock is flat and the channel wide, two giants are necessary to drive the gravel across the channel to the sluices. Here one giant drives the gravel from 100 feet to 150 feet and the second giant drives it from 100 feet to 150 feet farther on to the sluices. This method is an economical one, since flume construction is reduced to a minimum.

High banks are worked off in benches of from 50 feet to 60 feet in height. If the gravel deposits are light, it is well to remove the top dirt first and the gravel last, since the gold is more easily saved by this method. If the gravel is heavy, however, work the top and bottom together, since the top dirt aids in moving the heavy materials.

In a hydraulic mine the first work for the engineer is to determine the value of the deposits, and from the topography of the surrounding country and from the character of the deposits determine the best method and the pressure necessary to work them. After this information has been obtained, run a preliminary ditch survey, giving the required head, from the mine to the source of the water supply, examine the topography of the country and the character of the formations through which the ditch must be constructed. Then, from experience, the engineer can decide from the topography the least expensive and best place to construct the ditch, and from the geology of the formations the proper grades to be established. Plans can now be made, cost of plant calculated, expense of working the whole estimated, and the least possible margin of profit appraised.

Ditch.—Put in waste gates every ¼ to ½ mile. As a protection against floods, flume all water in gulches over the ditch, unless a flume is to be built across the gulch, in which case put a turn-out gate in the flume. Gates often save much expense when the ditch breaks. In crossing large canyons, the inverted siphon may be cheaper than either ditch or flume. When lumber is cheap and the life of the mine is not more than ten years, and a ditch could not be utilized for irrigation or power purposes after the mine is exhausted, build a flume. The first cost of a flume, in most instances, is less than that of a ditch and the repair is very much less. A flume is also more efficient, not only in the amount of water conveyed by it, but in the time saved in repairs when the weather is bad and water plentiful.

Pressure Box.—The penstock, or, more properly speaking, the pressure box, should be spacious and the water should stand not less than 4 feet deep over the entrance of the pipe to prevent the admission of air. Some miners put a partition in the pressure box to prevent sand, gravel, etc., from entering the pipe. A better method is to increase the depth of the ditch 18 to 20 inches below grade from the pressure box for 100 feet up the ditch and put in a waste gate deep enough to drain the excavation, so that the sediments can be caught in the excavation and sluiced out at the gate. Provision must be made in the flume leading to the pressure box to prevent trash from entering the pipe, by means of a rack, and for the overflow when the gates in the pipe line have been closed. In order to facilitate the removal of the trash accumulated on the rack, design the supply flume so that the overflow shall pass back through the rack. Use 2-inch heart lumber in the construction of the pressure box and make it portable.

Pipe Line.—The design and lay of the pipe requires engineering skill and experience. Many obstacles often lie in the course of the pipe line. A 24-inch pipe, owned by the Railroad & Mining Co. of Denver, Colo., crosses the Klamath river on a suspension bridge. The span is about 380 feet and the two cables are each 2 inches in diameter.

To reduce friction, as well as expense, use the shortest pipe line practicable with a minimum number of elbows and depressions. As a material of pipe construction, iron is better than steel in some districts, since steel oxidizes readily. I know of a pipe line constructed of steel that lasted only two years, and on the same mine they are using sheet iron pipe of the same gauge that has been in service about twenty years. The pipe in the mains should be properly covered with a mixture of coal tar and asphalt, which makes a permanent protection. Always test the tar before using it. Fig. 1 illustrates a good method of pipe construction, since pipe manufactured in this manner can be easily made water tight or repaired quickly. Much of the hydraulic pipe is put together at the mine, and practically all of it is repaired at the mine. The pipe ordinarily used is 7, 9, 13, 15, 16, 20, 22, 30, 36 and 40 inches in diameter and formed of Nos. 8, 10, 12, 14, 16 and 18 Birmingham gauge sheet steel or iron. The lengths of the sections are usually 12 and 17 feet, but may vary from 8 to 20 feet, depending somewhat upon the diameter of the pipe and the character of the country.

The sections should be put together stovepipe fashion, i. e., one end is simply inserted into the end of the next piece 3 or 4 inches. If the joint is not tight and the pipe telescopes too much, use tarred cloth strips. Never use wood wedges; they injure the pipe. To prevent flattening of the pipe, the supports under the pipe should be placed back of the joint and directly under the first joint of the section; thus at A and B. (See Fig. 2.) Anchoring the pipe

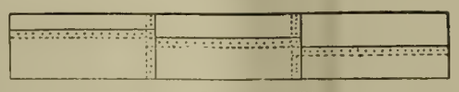


Fig. 1.—Riveting in Pipe.

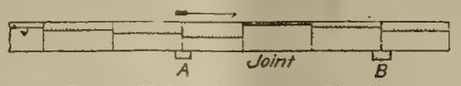

Fig. 2.—Method of Supporting Pipe Line.

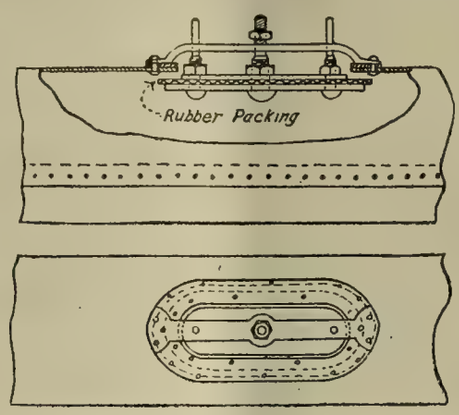

Fig. 3.—Air Valve.

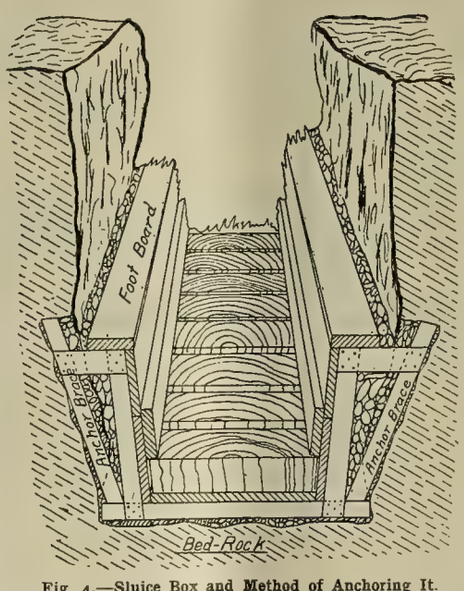

Fig. 4.—Sluice Box and Method of Anchoring It.

line is necessary only where elbows, tapers, Y's or gates occur, unless the slope is considerable. Put in air valves at all points where vacuums are likely to occur. An excellent air valve which any blacksmith can make is shown in Fig. 3. In general, the expansion in hydraulic pipe lines is neglected and is reduced to a minimum by keeping water in the pipes by means of the gates. Gates, also, reduce leakage to a minimum. Sawdust, dirt and fine leaves are used to stop leakage. The diameter of the pipe at the head should be large and decrease as the head increases according to the laws of hydraulics. The effective pressure should be made as great as possible with reasonable outlay. Many miners err here, not knowing how to make the proper calculations. For economy, the gauge of the pipe material should decrease directly as the pressure.

The introduction and filling of the pipe line with water must be undertaken with great care. The inflow must be gradual to prevent the admission of air. If this precaution is not taken, serious accidents may occur, especially with high heads. The gate at the pressure box, therefore, must be gradually opened. Rapid opening of gates at any point on the main or distributing lines should not be tolerated, since shocking, bursting, bucking or collapsing may occur.

Giants.—The two types of giants in general use are the single and double jointed. The double-jointed giant is more efficient, as far as the efficiency of the stream is concerned, but the single-jointed machine is more efficient in manipulation, since it can be lubricated without turning the water out of the machine, which is necessary with the other style. The double-jointed machine is safer under high heads (200 feet or more).

The double-jointed giant is manufactured with or without king bolt. The latter type has a clear water way; hence is more efficient, but is objectionable since it is ball bearing. The balls often crush, get lost or work hard because of the dirt and sand entering into the grooved ring. The king bolt type is simpler in construction and is a good machine for all practical conditions. There are eight sizes of giants which use nozzles from 1½ inch to 10 inches in diameter, and which weigh from 390 pounds to 2300 pounds. The deflector is an indispensable attachment for giants of all sizes, except the No. 1. From 20% to 80% more material can be piped by its application. If it is not adjusted properly and handled with care, it transposes the giant into a demon of destruction. Many a poor pipeman has been killed by one through carelessness. Before deflectors were invented three men were required to move a large giant under a high head, but now, by use of the deflector, a child can direct it at will with one hand. The higher the pressure, the easier it works. The giant is bolted to an 8x8-inch to 12x12-inch timber, 6 or 7 feet long, called the bed piece or brace block. In setting the giant, stake against this bed piece and brace against the stakes. Catalogues and books on the setting of the giant recommend driving bars of iron or steel through holes, bored for the purpose, through the ends of the bed piece into the ground to secure the giant firmly. This is not practical where there is bed rock. Stakes staked against the bed piece are far better where anything can be driven, and they hold more than iron bars and can be more easily removed. All the moving parts of a giant should be kept well lubricated, since dry surfaces cause serious accidents (breaking king bolts, etc.). A mixture of one part tallow, one part lard, and one part soft, fresh pitch makes an excellent lubricant which is practically water proof.

It is important that the giant is set securely, otherwise accidents may not only be serious to the pipeman and expensive to the operator, but the location for the machine may be damaged to such an extent that resetting is made difficult. Selecting the location for the giant requires much skill and experience, especially when the bank is high. The inexperienced operator would be wise to let his pipeman select the location, provided, of course, the pipeman is experienced. No miner can afford to have any but the best pipeman, since the success of the mine depends largely upon him.

The Bedrock Sluices.—Since the mission of the bedrock sluice is to catch the gold and convey the materials to the dump, it is the most important apparatus of a hydraulic mine. Great care must be exercised in its design, location and construction. The water supply, the character of the ground to be mined, and the topography of the outlying country determine the grade. Sands require heavy grades and shallow sluices. The usual grade is 6 inches per box of 12 feet, but may vary between 1 inch and 12 inches per box. Give the head boxes a little less grade and increase slightly toward the dump. The tail sluices are generally in poorer condition and therefore require more grade.

Wide, shallow sluices are used in mines where the deposits are light, grades scant, and dumps of little depth. If the gravel is heavy (many large boulders) and the dump is poor, use deep, narrow sluices. The depth of the water in the sluices, in this case, should be equal to the width of the flume. Their width and depth, therefore, depend upon the character of the material, as well as the water supply.

Sluices should be set as straight as possible, but if curves are necessary, raise the outside bend according to the degree of curvature and construct the curve of half boxes (i. e., 6-foot lengths).

If the rim of the channel is high and wide or the channel itself is very wide, the sluices are set in tunnels arranged so that they will remain in the bedrock at the lowest point of the channel, and should be run as near to the center of the deposit as practicable before connecting with the surface workings. This last point gives the maximum amount of mining ground per tunnel. Open bedrock cuts are preferred where practicable, and are cheaply excavated by loosening the bedrock in the proposed line of the flume with powder and piping out the material with the giant. Tons of material can be moved quickly and cheaply by the application of this method. After the cut is finished to grade and the flume set therein, anchor the flume in the cut (a method of anchoring is shown in Fig. 4), put in the riffles or blocks, put an obstruction in the flume, and run the sluices full of gravel to prevent them from floating. Next, bury the sluices with gravel. All the spaces around the flume will thus be filled and the grade and form of the flume preserved. Lastly, remove the obstruction placed in the sluices and run the materials through; the flume is now ready for use.

Sluices should not be less than 240 feet in length for economical mining, since fine gold and mercury may pass through. This is true, especially if there

*Abstract of Colorado School of Mines Bulletin.

is much sand or clay in the deposits. Much of the gold in all gravel deposits is fine and some of it is rusty. Undercurrents or grizzlies are used to catch these products which would otherwise be lost.

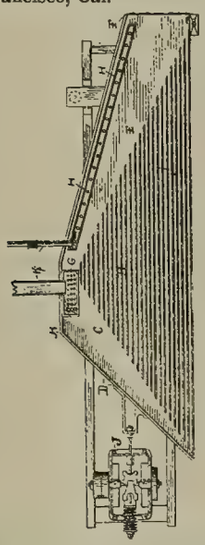
(TO BE CONTINUED.)

Mining and Metallurgical Patents.

PATENTS ISSUED JULY 25, 1905.

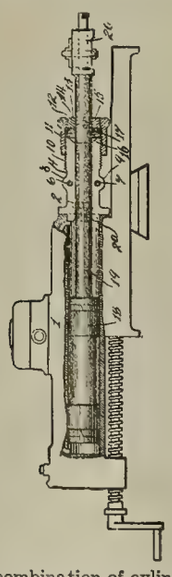
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE CONCENTRATING TABLE.—No. 794,928; W. G. Dodd, San Francisco, Cal.



Transversely inclined ore concentrating table provided on its working face with series of longitudinally extending collecting riffles, which riffles gradually increase in length from uppermost riffle to lowermost one of series, receiving and terminal ends of each riffle extending beyond ends of preceding riffle, there being unriffled or plain surface to table intermediate terminals of riffles and its head and tail respectively, and feeding means so arranged at upper edge of table as to cause portion of pulp delivered onto table to overlap uppermost riffle toward head, so as to feed directly to projecting ends of part of subsequent riffles.

ROCK DRILL.—No. 795,169; G. S. Power, Passaic, N. J.

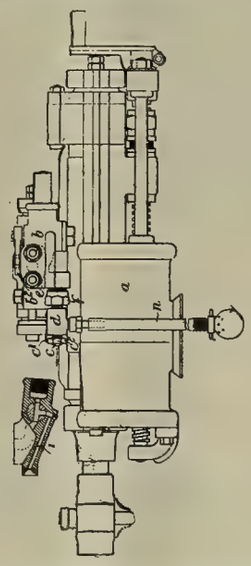


In rock drill, combination of cylinder, piston having piston rod integral therewith, neck or front head composed of halves detachably secured together, separably connected to cylinder and adapted for working fit with piston rod, threaded portion upon neck or head, adjustable gland adapted to work upon threaded portion, tapered opening in gland, and tapered split bushing adapted to fit within opening and to surround piston rod and pack same when gland is adjusted.

PROCESS OF PRODUCING TUNGSTEN STEELS.—No. 795,517; E. D. Kendall, Brooklyn, N. Y.

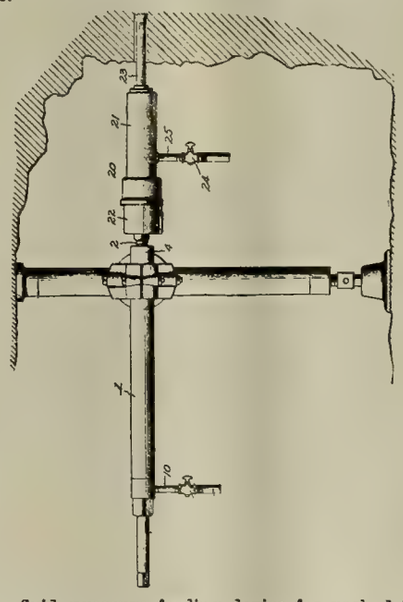
Process of producing alloy or alloys containing tungsten and iron by preparing mixture of tungsten ore, metallic zinc and iron and subjecting mixture to thermal action of electric current, in electric furnace.

APPARATUS FOR ALLAYING DUST IN CONNECTION WITH ROCK DRILLING MACHINERY.—No. 794,752; W. C. Stephens, Camborne, England.



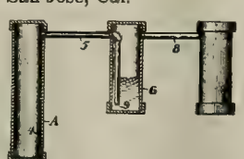
In device of class described, combination with air supply tap of rock drill, of spraying device provided with adjustable nozzle adapted to be rotated to regulate quantity of spray, blade spring secured to spraying device and constructed to bear upon face of nozzle to prevent same from turning, spraying device being directly connected by ball-and-socket joint to tap whereby direction of spray may be varied, tap being provided with admission port for compressed air and independent passages to rock drill and spraying device and plug in tap constructed to admit supply of compressed air to either or both of passages whereby rock drill and spraying device may be operated separately or together.

FLUID PRESSURE FEEDING DEVICE FOR ROCK DRILLING ENGINES.—No. 795,735; C. H. Shaw, Denver, Colo.



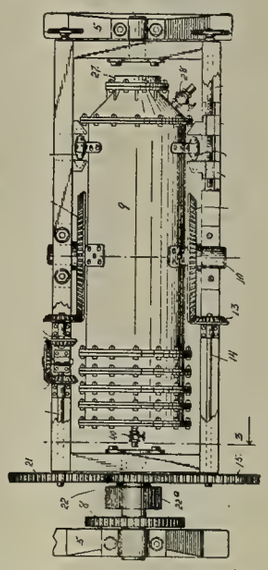
In fluid pressure feeding device for rock drilling engines, combination with pneumatic hammer drill of fluid pressure feed cylinder and piston, comprising cylinder, piston reciprocally mounted at one end in cylinder and secured at opposite end to pneumatic hammer, and plug shaped cylinder head threaded to rear end, motive fluid inlet passage extending through plug cylinder head into cylinder at rear end of piston rod and provided with threaded hole in end, and brace bar comprising bar loosely threaded to end of cylinder head at one end and provided with wrench receiving surface at opposite end.

ORE REDUCING APPARATUS.—No. 795,471; W. T. Armstrong, San Jose, Cal.



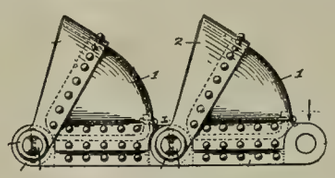
In portable apparatus of character described, tube of uniform diameter threaded at ends, removable closures for ends and rendering tube air tight, tube having inner lining capable of being reduced to carbonaceous form by heat, condenser, and pipe leading from tube to condenser tube adapted to contain body of carbon-forming material mixed with ore, and pipe having end within condenser provided with check valve to prevent backflow into tube.

ORE TREATING AND FILTERING APPARATUS.—No. 795,774; T. D. Jones, Denver, Colo.



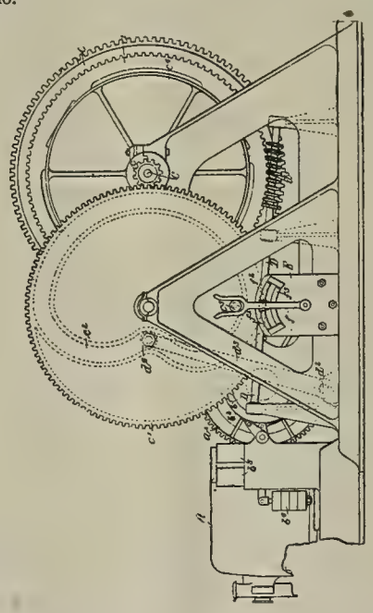
In combined ore treating and filtering apparatus, combination of frame trunnioned at extremities to rotate, barrel mounted in frame to rotate therewith on longitudinal axis and trunnioned in frame to rotate independently of latter on axis extending at right angles to longitudinal axis.

EXCAVATING BUCKET.—No. 795,417; H. H. Postlethwaite, San Francisco, Cal.



Excavating bucket, same comprising body portion, cutting lip secured to upper edge thereof, ends of lip terminating in bearings which project below bottom edge of bucket, bottom plate and link section, link section being united to lower edge of bucket's body, link section being provided with forwardly projecting and rearwardly projecting bearing ears.

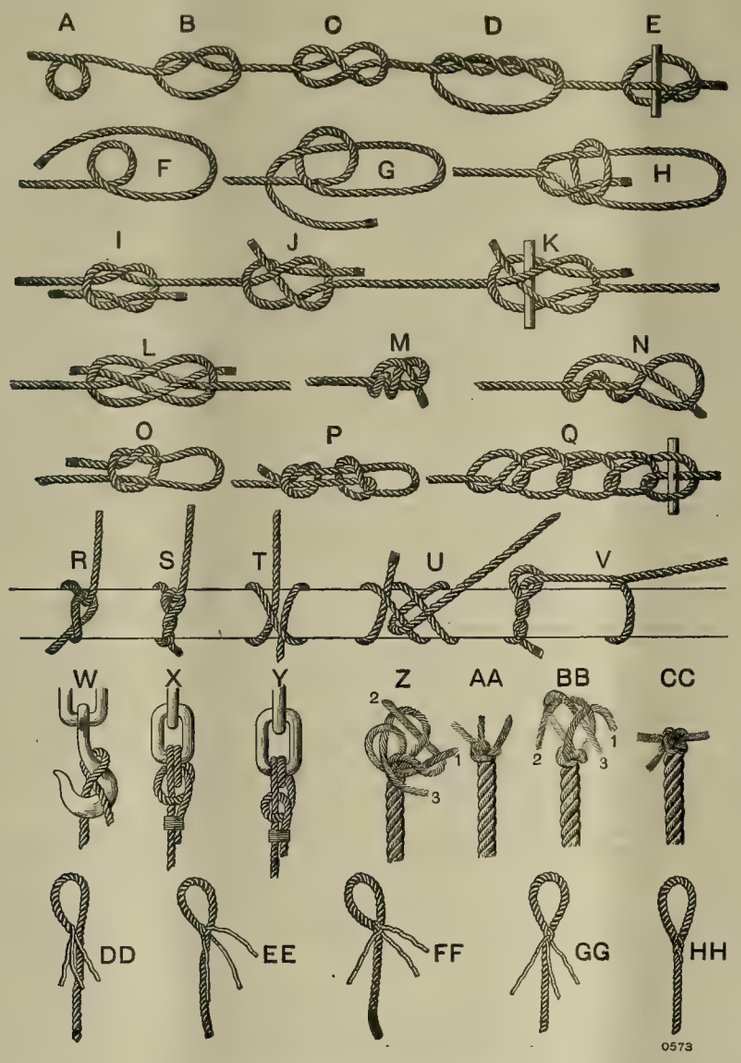
SPEED CONTROLLING DEVICE FOR HOISTING MACHINERY.—No. 795,641; J. McGeorge, Cleveland, Ohio.



Combination of continuously operating motor, structure driven thereby, switch, electrically actuated clutch in circuit with switch and connecting motor with driven structure, brake, and automatic means operated from driven structure constructed to mechanically actuate switch to effect action of clutch and of brake.

Knots, Hitches and Bends.

Miners are daily required to make use of ropes in various ways, both on the surface and underground, and it is very desirable that the miner know how to quickly make a safe knot, hitch or bend in a rope. It is not only the necessity of making a secure knot, but forming one which may readily be untied. For instance, all miners are or should be thoroughly familiar with the combination known as the "timber and half hitch." This is illustrated in the accompanying sketches at V. Its utility is well known and the sketch is both familiar and well made. As this well-known form of hitch appeals to those who frequently are required to make use of it, so each of the other knots, hitches and bends have their particular usefulness, and should be carefully studied and practiced, until each of them can be readily made. The accompanying cuts and descriptive matter are from the handsome pamphlet, "Manila Rope," issued by the C. W. Hunt Co., of 45 Broadway, New York, on transmission and hoisting rope:



Useful Knots and How to Tie Them.

KNOTS, HITCHES, BENDS.—The principle of a knot is that no two parts which would move in the same direction, if the rope were to slip, should lie alongside of and touching each other.

A great number of knots have been devised, of which a few of the most useful are illustrated. In the engravings they are shown open, or before being drawn taut, in order to show the position of the parts. The names usually given to them are:

A—Bight of rope.
B—Simple or overhand knot.
C—Figure 8 knot.
D—Double knot.
E—Boat knot.
F—Bowline, first step.
G—Bowline, second step.
H—Bowline, completed.
I—Square or reef knot.
J—Sheet bend or weaver's knot.
K—Sheet bend with a toggle.
L—Carrick bend.
M—"Stevedore" knot completed.
N—"Stevedore" knot commenced.
O—Slip knot.
P—Flemish loop.
Q—Chain knot with toggle.
R—Half hitch.
S—Timber hitch.
T—Clove hitch.
U—Rolling hitch.
V—Timber hitch and half hitch.
W—Blackwall hitch.
X—Fisherman's bend.
Y—Round turn and half hitch.
Z—Wall knot commenced.
AA—Wall knot completed.
BB—Wall knot crown commenced.
CC—Wall knot crown completed.

The figures DD to HH represent the eye splice commenced and completed.

The bowline G is one of the most useful knots; it will not slip, and, after being strained, is easily untied. It should be tied with facility by every one who handles rope. Commence by making a bight in the rope, then put the end through the bight and under the standing part as shown in the engraving, then pass the end again through the bight, and haul tight.

The square or reef knot I must not be mistaken for the "granny" knot that slips under a strain. Knots H, K and M are easily untied after being under strain. The knot M is useful when the rope passes through an eye and is held by the knot, as it will not slip, and is easily untied after being strained.

The timber hitch, S, looks as though it would give way, but it will not; the greater the strain the tighter it will hold.

The wall knot looks complicated, but is easily made by proceeding as follows: Form a bight with strand 1 and pass the strand 2 around the end of it, and the strand 3 around the end of 2, and then through the bight of 1, as shown in the engraving Z. Haul the ends taught, when the appearance is as shown in the engraving AA. The end of the strand 1 is now laid over the center of the knot, strand 2 laid over 1, and 3 over 2, when the end of 3 is passed through the bight of 1, as shown in the engraving BB. Haul all the strands taut, as shown in the engraving CC.

The "Stevedore" knot M, N is used to hold the end of a rope from passing through a hole. When the rope is strained the knot draws up tight, but it can be easily untied when the strain is removed.

KNOTS ARE WEAK.—If a knot or hitch of any kind is tied in a rope its failure under stress is sure to occur at that place. Each fibre in the straight part of the rope takes proper share of the load, but in all knots the rope is cramped or has a short bend, which throws an overload on those fibers that are on the outside of the bend and one fiber after another breaks until the rope is torn apart. The shorter the bend in the standing rope the weaker is the knot. (See the experiments of Prof. Edward F. Miller, Massachusetts Institute of Technology, in "Machinery," page 198, March, 1900.) The results given in the following table are approximate, but are sufficient to cause engineers to be cautious in all rope fastenings employed in important work.

Table of the approximate strength of knots compared with the full strength of the rope based on Prof. Miller's experiments:

APPROXIMATE EFFICIENCY OF KNOTS IN A PERCENTAGE OF THE FULL STRENGTH OF THE ROPE.

	The Efficiency of the Knot.
Rope dry—average of four tests from the same coil as the knots	100
Eyesplice over an iron thimble	90
Short splice in the rope	80
Timber hitch, round turn, and half hitch	65
Bowline slip knot, clove hitch	60
Square knot, weavers' knot, sheet bend	50
Flemish loop, overhand knot	45

Personal.

R. B. STANFORD of Columbia, Cal., has returned from New York.

R. S. LIGHT is manager Mollie S. M. Co., operating near Creede, Colo.

ED. LYNCH has resigned as superintendent Keystone mine at Amador City, Cal.

C. R. DOWNS has been made superintendent Keystone mine at Amador City, Cal.

S. DAVIS of Butte, Mont., has taken charge Cork mine at Kaslo, Slocan district, B. C.

M. A. SHEETS has been appointed superintendent Overland mine and mill at Sunshine, Utah.

S. H. BASHOR, manager Copper Blush mine at Jamestown, Colo., is making a short Eastern trip.

E. D. TRENAM, manager Deer Lodge mine, Deer Lodge, Nev., is directing work at the mine.

J. L. PARKER is mine superintendent Brown Alaska Co. at Hadley, Prince of Wales island, Alaska.

W. H. ALDRIDGE, manager Trail smelter at Trail, B. C., is on a trip to Montreal and New York City.

E. P. MITCHEL of Santa Barbara, Cal., president Goldstake M. & M. Co., has been in Deadwood, S. D.

J. C. BRENNON, superintendent La Mina Santo Tomas at Torres, Sonora, Mexico, has been at Houghton, Mich.

J. PARKE CHANNING has completed an examination of the mines of the Nevada Copper M. Co. at Ely, Nev.

R. K. HUMPHREY has resigned as manager Montana Zinc Co., Walkerville, Mont., to engage in general engineering work.

H. J. RYAN of Cornell University has taken up his duties as professor of electrical engineering at Stanford University, Cal.

FREEMAN ROWE has been appointed foreman Hecla mine at Wallace, Idaho. A. M. Perkins and Geo. Wall have been made shift bosses.

A. W. JENKS has returned to Salt Lake City, Utah, after four months spent in the examination of mining properties in Nevada and Utah.

D. T. PARKER, formerly superintendent Ohio & Colorado S. & R. Co. at Salida, Colo., is superintendent Ponderay Smelting Co., Sand Point, Idaho.

JOS. PORTER, recent superintendent Fairview mine, Papoose, Cal., has taken the management of the Bonanza King mine, Trinity Center, Trinity county, Cal.

J. W. GATES, for several years in the Denver office of the Mine & Smelter Supply Co., has been appointed local manager of their Salt Lake City, Utah, branch.

LOUIS B. CARR, formerly of Pueblo, Colo., has formed a partnership with Geo. H. Sauer and opened a custom assay and ore shippers' office at 1711 California street, Denver, Colo.

MATTHEW BRODIE, formerly of the Pittsburg office, has been appointed local manager of the Salt Lake City branch of the Sullivan Machinery Co. of Chicago, with offices at No. 128 Keith building.

THEO. F. VAN WAGENEN, who recently returned from South Africa, now makes his headquarters in the City of Mexico. For the next ninety days he will be traveling through Yucatan and the southern States of the Mexican republic.

J. R. HENDRA, superintendent Santa Fe Copper & Gold Mining Co., with mines in Alamos, Sonora, and also in Sinaloa, Mexico, has also taken the superintendency of the San Bernardo Mining Co.'s mines in Aduana, Alamos, Sonora, Mexico.

Obituary.

WM. COLLEY, a well-known zinc and lead miner, died in Leadville, Colo., July 23, of pneumonia, aged 52.

HENRY RAMDOUR, superintendent Globe mine at Trinity City, Cal., died recently at Winnemucca, Nev.

WILLIAM JESSOP died on July 4 at Thornsett Lodge, Bradfield, England, after a long illness. Mr. Jessop was born October, 1856, was educated at Repton, Germany, and at Cambridge. At the time of his death and since 1887 he was chairman of William Jessop & Sons, Ltd., steel manufacturers of Sheffield, England, and was the head of the fourth generation of the Jessop family in control of the firm—the business having been established in 1774. He was also president of Jessop Steel Co. of Washington, Pa., president of the Jessop hospital for women, an institution founded by his father, the late Thomas Jessop, to which he contributed over $200,000, and which was zealously and liberally supported by his son. He was noted for his kindness and generosity and was greatly esteemed by all. He visited Australia, Japan and America in 1903.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ARIZONA.

Gila County.

The old shaft at the Old Dominion plant at Globe has been abandoned for all hoisting purposes and power applied to the new shaft. The gallows frame has been taken from the old shaft and the steam plant is to be removed. The new concentrator will be operated on August 1. The fourth furnace will be put in at once and serve as a relief for the three now in commission. They can be repaired alternately without lessening the output.

Mohave County.

The Santa Inez M. Co. is working the Mohave mine, near Boundary Cone, in the Vivian district.——Superintendent Malone is putting in a hoist at the Fay mine, south of Kingman.——The German-American mill has been closed down owing to the failure of the water supply. Men have been put to work on the Pioneer shaft and it will be driven down into the water stratum. If sufficient water is developed the mill will be started up again.——At the Pinkham mine men are taking out water and getting ready to sample the property.——A hoist will be put in at the Midnight mine and the property unwatered. E. C. Eckis is superintending work on both mines.——Work on the Minnesota-Connor mine at Chloride is under the management of F. H. Griffith. A large compressor is being put in and machine drills will be put in at once.

Pinal County.

(Special Correspondence).—The Arizona-Pacific Copper Co., whose property is near Florence, has put in a complete shaft equipment, including a 35 H. P. hoist, air compressor, machine drills, electric light plant, pumps and other equipment. The company is engaged in sinking a shaft to a depth of 1000 feet. It is down to a depth of 350 feet, where a station has been cut and a crosscut made to the vein. The main office is 702 Stevenson Building, Indianapolis, Ind. F. P. Jeffries is president, J. W. Sharpe vice-president and general manager and E. R. Stafford superintendent. The property is said to show several smaller veins, assaying 3% to 20% copper and $5 to $20 gold per ton. A quartz porphyry dyke, 1200 feet long and of variable width, has been shattered and cemented by veins carrying cuprite, melaconite and chalcocite giving 3% copper.

Florence, July 31.

(Special Correspondence).—The Big Lead M. Co. has purchased copper claims adjoining the Ray mines, 5 miles from Kelvin. A double-compartment shaft has been sunk to a depth of 100 feet, and the copper ore body has been crosscut at the bottom of the shaft to a width of 100 feet. A successful concentration test of the ore is said to have been made at the old Bob Tail mine. A site is being graded on which to build a concentrating and leaching plant with a capacity of 100 tons daily.

Kelvin, August 1.

Yavapai County.

Yavapai county has agreed to accept the road leading from Poland past the Buffalo-Arizona camp to the Michigan-Arizona mines. The opening of the road makes an improvement in the vicinity, furnishing access to the mines from Poland. Previously it has been necessary for the companies operating south of the Buffalo-Arizona to have the freight and mail sent to Prescott, 15 miles away.——On the Gold-Copper Co.'s ground, south of the Senator mine, near Prescott, the company is completing a camp that will accommodate fifteen men until reduction begins. Thos. Marmont is superintendent.

T. J. Rigby, president and general manager of the Rigby M. & R. Co., is establishing the Pohle-Croasdale metal volatilization process at Mayer. All the buildings, ore bins, etc., are completed, the machinery has been made, much of it is on the ground and the rest in transit. The works will be ready to start up by October, beginning with four furnaces capable of handling 125 tons per day. The superintendent and construction engineer is H. A. Clarke. The operation is first one of crushing the ore; second, its subjection to a desulphurizing roast to expel the sulphur; third, volatilizing the metals and, fourth, condensing them in chambers provided for the purpose, where 95% to 98% of the values are said to be recovered. It is automatic.

CALIFORNIA.

Amador County.

At the Volcano quartz mine on the Mokelumne river, near West Point, a 10-stamp mill is being put up.——F. Jackson and J. Podesta are working their quartz mine on the Spagnoli land, near Clinton.——It is reported that the Zeila mine is changing from the old to the new hoist. The hoist has been all ready, but the work of changing has been delayed on account of the flow of water. The mill will be shut down for two weeks while the change is being made.

Butte County.

The main tunnel of the Gold Bank quartz mine, at Forbestown, has been cleaned through its length of 2200 feet.

The Veigne ranch, 5 miles east of Honcut, consisting of 1430 acres, has been bonded by W. E. Crook for mining purposes.

Del Norte County.

(Special Correspondence).—It is reported that a 500-ton concentrating plant is to be put in at the Monumental mine at Monumental by T. W. M. Draper. The ore is soft and it is planned to concentrate twenty-five tons to one.

Monumental, Aug. 1.

Contra Costa County.

(Special Correspondence).—The new smelting and refining plant of the Mountain Copper Co., near Martinez, is about one-half finished. The lead tanks of the sulphuric acid plant have been put in and the building partly built. Most of the buildings have been completed and the furnaces and boilers are being put in.

Martinez, Aug. 3.

Los Angeles County.

A low-grade gold property in Millard canyon on Mount Lowe is being developed by a Milwaukee company represented by H. J. Pullen.

Inyo County.

The Great Western Ore Purchasing & Reduction Co. is running ten stamps at Keeler and five at Swansea. Slag from Cerro Gordo and the Swansea furnaces is being worked, and Darwin's furnace sites will also be worked.

Merced County.

L. K. Vaughan of Oroville is prospecting the bed of the Merced river, near Snelling, with a drill. The ground will be worked with a dredge, if prospects warrant.

Nevada County.

Superintendent F. L. Whipple has temporarily suspended operations on the Federal Loan mine, near Nevada City, while the surface improvements are being made, during which time only the pumps will be kept going and a small crew employed. The mine is down to the 1000-foot level and all ready for drifting and stoping. Since the present company took hold they have sunk 200 feet. —— H. German and Weinman Bros. of North San Juan, who are driving ahead the long tunnel at the Orient gravel mine, near Nigger Tent, found gravel while making an upraise. They connected with the shaft and have fine air for working in the main tunnel. The gravel is 60 feet above the tunnel, pitching at a steep angle into the ridge. To reach the bottom of the channel will require 300 feet of tunnel.

Superintendent W. H. Dunlap is putting in a 10-drill compressor at the Lecompton mine at Nevada City.—— The debris commission have granted permission to the Omega Co. to build another restraining barrier in the canyon below their gravel mine at Omega, near Washington. Superintendent W. M. Wilson expects to commence work as soon as the preliminary arrangements can be completed, as it is desired to have the barrier finished by next fall.——R. I. Thomas and associates have an option on the Hustler holdings, near Cherokee, on the Bloomfield channel.

Placer County.

The Hidden Treasure mine is working 140 men and making good progress on the air shaft near Forks House.——The Baltimore mine at Forest Hill is running with thirty men and putting in a 50 H. P. engine.—— At the Mayflower mine, near Forest Hill, they have struck the Orino channel.——At the Tadpole mine, at Secret House, four men are driving the main tunnel.—— The Jarvis mine, at Red Point, is being worked with twenty-five men.——About fifteen men are employed at the Red Point mine.——The Alameda mine machinery at Black Canyon is being put in order, electricity replacing steam, and forty men will be employed.——The Paragon mine, at Bath, is working twenty-five men on good pay dirt, two shifts a day.——James & Smiley have four men at work at the Prairie Flower mine, at Canada Hill, developing.——The Salvation mine, at Canada Hill, has closed down for a short time.——Drifting is to be started at the Santa Fe mine, at Canada Hill.——In the Golden West mine, at Canada Hill, the pay channel is said to have been reached.

The Acacia, or James mine, near Damascus, has been sold to a San Francisco company by G. and H. W. McAulay.

San Bernardino County.

W. V. Holley and J. Meyer of Los Angeles have bought from J. Nelson and A. E. Moore their claims, near Keswick Springs, on the desert, for $40,000. The ore showed high values on the surface, and at a depth of 150 feet increased in value. Machinery will be put in.

San Diego County.

Near Julian, the Julian Con. M. Co. is putting up a 50-ton roasting plant and also a 20-stamp mill and cyanide plant between the Helvetia and High Peak mines. New shafts are being sunk on both mines and the old ones are being retimbered, to be used for ventilation and escape. The Julian Con. M. Co. also owns the Warlock mine, between Julian and Banner, on which they are running a crosscut to tap the vein. This crosscut is 800 feet long. W. J. Proud is in charge of the High Peak mine, D. F. Lane of the Helvetia, D. S. McPherson of the Warlock and D. G. Juewitt is in charge of the milling and cyanide plant. W. W. Boswell is the general superintendent.

Shasta County.

D. McCarthy proposes to open up the Dry Slide mine above Keswick.

Sierra County.

(Special Correspondence).—The Forest City M. Co. have started men to work and this coming week will have eight men working. New cars have been taken to the mine and work will be crowded as much as possible, and as soon as there is enough money will put on six more men, and it will take but a short time to develop the channel.

Forest City, Aug. 1.

At Forest City work has been started on the Mabel Mertz mine, extending the West tunnel to tap the gravel channel, which was struck some time ago.—— Superintendent E. Kuhfield has been driving the tunnel at the South Fork mine, near Forest, and it is now believed to be under the gravel channel.

At the Mountain mine the tramway which was destroyed by fire last December is being repaired. It is in operation by means of a temporary chute from the level of No. 3 tunnel to the lower bin of the upper terminal. This arrangement is temporary, but will enable the mill to be started and supplied with ore until complete repairs are made. A gyratory crusher is to be put in at the mine. The rock crusher will be driven by a 50 H. P. electric motor, which will receive its current from a 75 K.W. generator at the mill. This plant will also furnish lights for both mine and mill, and later will be used to drive air compressors at the mine. L. H. Carver is superintendent.

Siskiyou County.

The Williams Point gravel mine, 10 miles above Happy Camp, has been sold by T. J. Nolton to Seattle, Wash., and Denver, Colo., parties, who propose to put in a power plant and pump water from the Klamath river for mining by hydraulic means. The experiment is said to have been tried successfully in Colorado, and it will be watched with interest, as there are many mines that could be worked but cannot be provided with ditches.

Stanislaus County.

T. Donohue, superintendent of the La Grange Ditch & Hydraulic M. Co., is building 8390 feet of flume, 5x7 feet. Work was stopped July 1 until this can be finished.

Yuba County.

It is reported that dredge mining is to be started, 4 miles east of Wheatland, by an English syndicate.—— Jas. O'Brien has bonded from T. Mahoney land in Linda township, 4 miles east of Marysville, for dredge mining purposes and also from John Raynolds.

COLORADO.

(Special Correspondence).—The "good roads' movement" which has occupied the attention of Denver the past week will undoubtedly bring forth good results. The question of good roads in this State is not one of comfort and convenience, but one of necessity. In the mountains, especially, the question needs agitation. The county, State and Government should work in harmony along this line and endeavor to make better roads. In many isolated districts and in places where the travel is heavy the roads are almost impassable, even during the summer months. It is to be hoped that the recent convention held in this city will do all and more than it has promised.——The Short Line Railroad, which was built by the mine owners and operators of Colorado Springs and Cripple Creek district, and which is reported as having been sold to the Colorado & Southern Railway, is to have an airing in the courts. James F. Burns, a heavy stockholder in the Short Line, has filed suit against the directors and charges secret manipulation in the sale of the stock. Burns has been refused, according to his complaint, the books and is bringing suit to compel them to allow him to examine the books. ——Activity is shown in several districts where the ores contain considerable zinc. On account of the high price for zinc, a large number of old abandoned mines and dumps are now working at a profit and many more are being started. In upper Clear Creek county this is proving true, as some of the old dumps are being worked at a profit, others are preparing to open up the old stopes as well as treat the dumps.

Denver, Aug. 1.

Clear Creek County.

(Special Correspondence).—The Independent M. Co. has recently purchased the old Griffith mine and are preparing to build a new concentrating mill for handling the old dump as well as the low-grade ores from the mine. The purchase price was $40,000 to be paid in seven months; twenty-five to thirty tons per month are being shipped at present. A new boiler will be put on the property. This company is also operating in East Argentine district. John Larson is manager, and Simon Anderson is superintendent.

Georgetown, July 28.

(Special Correspondence).—It is reported that the Empire Co. intend building a new smelter at Empire station, on Clear creek. A number of tests have been made, sufficient ore procured and the site of the smelter selected.——The Commodore Co., in which A. E. Reynolds is interested, is pushing its Commodore tunnel into Red Elephant mountain to develop mines in that mountain.——The Big 40 tunnel, being driven from Chicago creek to Clear creek by the Big 40 M. & T. Co. of Denver, has opened an ore shoot in the first lode.——The Two Sisters, or the American Sisters, are sinking a shaft to be sunk 200 feet.——The Joe Reynolds mine is shipping high-grade ore. A new ore washer has been put in at the mouth of their working tunnel to wash the dirt taken from the old stopes before it is sent to the concentrator. This mine is being worked through a tunnel driven by the company to drain the old workings, but may eventually be worked through the Big 40 tunnel and the Gold Valley tunnel.——The Mint lode at Empire is working.

Empire, July 29.

(Special Correspondence).—Stephens & McGroth have a lease on the old Mendota mill and dump and upper workings of the mine and are shipping 100 tons of concentrates per month. The dump ores run high in zinc. ——The new mill of the Dives-Pelican Co. is in operation, but they are putting in a larger size motor, as the one now in place is not of sufficient size to allow them to run full capacity.

Silver Plume, July 29.

(Special Correspondence).—On the ground on Chicago creek, where gold was first discovered in Clear Creek county, by George A. Jackson in 1858, is the new stamp and concentrating mill of the Waltham M. & M. Co., M. W. Tanner, president; A Anderson, treasurer. The mill contains twenty stamps, Elspass mill, two Wilfleys and one jig and has a capacity of 100 tons per day. The cyanide plant contains six steel tanks with a capacity of 100 to 150 tons each. Everything in the mill is automatic. The shaft on the property is down 150 feet and is to be sunk to the 500-foot level.——The Bonita mill, F. Read, manager, is adding 1000 square feet of canvas tables to better enable them to handle the ore they are receiving.

Idaho Springs, July 31.

A right of way through the Silver Gem tunnel at the head of Silver Age gulch has been secured by the Fostoria G. M. Co., which owns the old Hall ranch, an old agricultural patent lying north of the dividing line between Gilpin and Clear Creek counties, and the tunnel will be extended several hundred feet to reach the principal veins on the ranch. A 60 H. P. boiler and a 4-drill

air compressor will be placed at the mouth of the tunnel. The Silver Gem tunnel is in 917 feet and is expected to cut the St. Joseph lode, after which it will cut the Galatea vein. W. E. Campbell of Idaho Springs is secretary and manager.——At the Ward mine on Jackson's bar at Idaho Springs, men are sinking the present shaft, now 165 feet deep, an additional 100 feet, the work to be done with double shifts using machine drills. A large flow of water is coming in, but it will not interfere with operations at present, as the mine is equipped with both steam and electric plunger sinking pumps. The cyanide plant is handling the entire tailings output of the mill. ——Work was to be started August 1 on an electric road to the mouth of the Wilcox tunnel from Clear creek. The line will run around the face of Lafayette mountain on a 6% grade, and will be from 1500 to 2000 feet above Georgetown. The road will be used almost entirely for carrying the Waldorf ores to market. The road will be built by C. J. Wilcox, manager of the Waldorf M. Co.

The Georgetown Courier says that considerable development work is being carried on in the Daily district. T. Tyler of the Duluth & Colorado M. Co. states that many persons are in the field. The Continental tunnel is in 130 feet.——The Tam O'Shanter Co., operating claims adjoining the Puzzler group, is employing men in development work.——The Red Mountain Co. is employing two shifts and excellent headway is being made. The property is showing good values in gold and silver. The crosscut tunnel started a few months ago is in 200 feet.——The Helen-Harold Co. is developing. L. W. Aldrich is putting in an upraise to secure good air.—— The Butler M. Co. has put in its machinery. The shaft is to be given another lift of 100 feet.——The Dunton claims are being operated by the Vigilant M. Co., under the management of J. Lundstrom. The lower adit is being driven ahead.

Manager C. H. Morris has made arrangements for more work at the mines of the Charter-Raton M. & M. Co. on Breckenridge mountain, near Empire. The tunnel is in 150 feet.

Gilpin County.

The new mill of the Gold Dirt M. & M. Co. at Perigo has been completed and is expected to be running by August 10. The stamps are rapid drop, each weighing 1100 pounds. The plant will be lighted by electricity. The mill ore will be hoisted from the tunnel level through a 100-foot upraise to the rear and top of the mill by elevator. The process employed is plate amalgamation, concentration and cyaniding. J. R. Anderson is manager.

Development at the Snowdon property, near the head of Silver creek, is being done by the Missouri-Colorado M. & M. Co. under the superintendency of T. J. Stroud. They are drifting in the shaft at the 100 foot point and at the 50-foot point they are stoping. No effort is being made to ship ores at present. They expect to resume sinking the shaft.—— J. F. Colby, owning the Mary and Starling claims on the north side of Silver creek, is timbering the Starling tunnel, intending to work that tunnel to open up the Mary vein.—— It is reported that the Claudia J. vein has been cut in the crosscut at a depth of 100 feet. Arrangements are being made for a steam hoist. It is owned by W. Kelly of Apex. —— The Branham syndicate, with F. L. Branham in charge of operations, owns the Golden Crescent group on Black mountain on the south side of Silver creek. —— The Golden Rod M. & M. Co. have not been working for some time on account of the large amount of water in the main shaft which has reached a depth of 235 feet, the development in the mean time consisting of driving the tunnel to cut the shaft. This tunnel is in 70 feet, and when it cuts the shaft it will drain the surplus water, when operations will be resumed in the main shaft workings, as by that time it is believed that the water can be handled to advantage. —— At the Maine Louise group on the south side of Silver creek, J. Taylor and G. B. Wilkinson propose to extend the main tunnel to get under the old workings. —— The Little Lallie Mines Co., operating on the east side of Michigan hill, have W. E. Garver in charge of developments. —— The Pine Creek Con. M. & M. Co. has resumed work on its Barrick group of mines on Michigan hill, the work being in charge of W. S. Barrick.

Grand County.

The new mill of the Williams Fork M. & M. Co. is in operation near Empire. The 1400-foot tram from the mouth of the tunnel to the mill has been completed.

Gunnison County.

The Buena Vista M. Co. has put in machinery on its property at Hancock, and will resume operations on its tunnel into Mount Chapman from the northeast side. The company proposes to drive this tunnel 2000 feet, cutting through Mineral hill and into Mount Chapman. Several veins will be cut.——Regan & McCarthy of Cripple Creek have leased and bonded the El Dorado property, in Waunita park, and commenced operations. Machinery has been placed on the shaft, and it will be sunk deeper.——At Camp Sherrod the Sunlight G. M. Co., which has been driving a long tunnel into Mount Chapman from the west, has opened some ore that runs $50 per ton. Manager W. M. Bacon has a car of ore ready for shipment. The tunnel is in 200 feet.——The N. B. C. Co. has started a tunnel into Brittle Silver mountain, having let a contract for a 500-foot tunnel. ——The Camilla M. Co., representing W. G. Smith and other Denver people, will resume operations on its tunnel on Pomeroy mountain. It is now in 800 feet and has cut several veins.

The Golden mine in Paradise basin is being worked by L. Stanley and I. Brown of Gunnison.——Geo. Kellogg, of the Chloride at Pitkin, has secured a lease on the Mono mill on Ohio creek and has men repairing it, and will treat by cyanide all the low-grade product of the mine.

Lake County.

The Twin Lakes Miner says Hughes & Osburn are operating their Lincoln gulch properties.——J. M. Low is working the Young & Morgan claim at Red Mountain. ——Wm. Wheeler and T. Corlett are working the Iron-Gold group at Red Mountain.——The Manhattan M. & P. property has let a contract to Garfield Chilson for extra development work.——Arthur Kindel et. al will start extracting ore next month from the Kindel claims, in Sayres' gulch.——The Blaine Electric is making rapid progress in their tunnel in Willis gulch, and are employing a number of miners.——The tunnel of the Mt. Storm property is progressing rapidly since Frank Low and Steve Dodge have secured the contract.—— Operations have been resumed on the Dewar and Bowman properties at Red Mountain, by Harry Bowman. E. J. Dewar will arrive later.——Work has been resumed on the Byby group belonging to E. Ludwig of Denver, and G. Hoover has secured the contract on the new crosscut tunnel that will tap the several veins at depth. The property is on Taylor Pass.

In Leadville the Western M. Co. is sinking two shafts, one above the Penrose and the other to the south of it. The upper shaft is the Home Extension, under lease to the Cloud City Co., which is 600 feet deep and will be sunk another 200 feet, to be on a level with the bottom of the Cloud City, and when sinking is completed the two shafts will be connected. The other shaft to be sunk is the Bohn, which is down 550 feet and will have to go down another 350 feet to reach the ore shoot from the Penrose.

La Plata County.

(Special Correspondence).—At La Plata the May Day new tram is running. They are shipping twenty-five tons of good ore daily. The second tunnel, being run to cut the vein at a depth of 1000 feet, is in 1100 feet, with 1000 feet more to be driven. Machine drills and three shifts of miners are at work.——A third shift is to be put on at the New Hopes mine as soon as the road is cleared of snow. Wm. Price of La Plata is manager. The tunnel is in 1300 feet, which leaves 450 feet to be driven before the vein is reached. The tunnel is being driven with machine drills, making 6 feet daily.——The Lucky 4 mine, in Burnt Timber gulch, owned by Cripple Creek parties, recently became one of the shippers in this section. Manager Sye Roe is working two shifts and is turning out five tons of ore daily.——The Bonnie Girl mill is being built and the management think they will start up by Sept. 1. The mill is a 50-stamp concentrating plant and will be operated entirely by electric power. Superintendent Al Beason has charge of the work.——Eastern parties are looking at the Neglected mine and are thinking of starting it.

La Plata, July 29.

Mineral County.

At the Amethyst mine, near Creede, A 100-ton milling plant is being put up. The plant was designed by L. H. Norton, manager, and J. J. Fitzgerald, superintendent of the milling department of Creede United M. Co. The equipment includes a 9x15 Blake crusher, Bolthoff automatic feeder, two sets 14x27 rolls, four trommels, four 4-compartments jigs, tables and two 5-foot Chilean mills. A novel mechanism is the shaking launder for dewatering the jig middlings before delivery to the mills. Power is furnished by two 80 H. P. boilers and a 14x36 Corliss-Murray engine. It will probably be working within three months. Cyrus Miller of Denver is the general manager and Frank Ullman superintendent of the Amethyst Co.——The East Willow mill above Creede is in operation, treating forty tons of ore daily. Chas. Loughridge is general manager.

Ouray County.

The Joker tunnel of the Red Mountain R., M. & S. Co. is in 1700 feet, the depth at the breast being about 350 feet. In its course of 7000 feet it is expected to cut the Guston ground at a depth of 417 feet, the Robinson at 500 feet depth, the Yankee Girl at the sixth level, and the Genessee at the 800-foot. Mining has been handicapped by the acid surface waters, which will be removed through the Joker tunnel. During the six months ending June 11, the tunnel was driven 1300 feet. During March 282 feet were driven, the ground being broken 12x14 feet, the tunnel in the clear being 7x8½ feet. Leyner drills, size 5A, are in use. Back holes of 11½ feet and cut holes of 13½ feet were drilled. Including drillers, muckers, sharpeners, twenty-eight men were employed. The tunnel is mainly in a hard blue porphyry. The tunnel is timbered for 1000 feet, the timbers being square-setted. A 250-K.W. dynamo has been put in for electric lighting and haulage. W. C. Aston has charge of work, and G. Crawford is manager. The general superintendent is G. B. Craft of Ouray.

The mill of the Treasury Tunnel M. & R. Co. at Red Mountain has twenty stamps dropping, with twenty more ordered and to be put in as soon as possible. The Treasury mill is said to be now producing twenty tons of concentrate a day—a ton to the stamp. W. J. Hammond is manager.——In the Bachelor district the Calliope is shipping as well as the Bachelor and within three months the Neodesha, on which the Arps Bros. have started three shifts to drive a 400-foot tunnel, will be producing. John Kelleher has charge of the Neodesha and Bachelor.

Park County.

It is proposed to run a transportation and development tunnel from near Alma through London mountain of the Mosquito range to the Ibex mine in Lake county. The distance is over 4 miles, and will give a depth of over 2500 feet—cutting the London veins at a depth of 2550 feet, 850 feet below the present 1700-foot workings. R. M. Sherwood and W. J. Kurt, of the London Mountain Railroad, Tunnel & Mining Co., are interested.

J. H. Thorne has started work at the Snowstorm placer, near Alma.——The Hilltop mine on Horseshoe gulch, 4 miles from Fairplay, has been leased by John Geering.——Wm. Bean has been shipping copper gold ore from the May Queen mine, near Alma.—— Geo. Shelton is shipping 200 tons of sulphide ore monthly from the Kentucky Belle, near Alma.

San Juan County.

Tunnel work is to be resumed by the Golden Monarch M. & M. Co. at its claims, near Gladstone.——The 20-stamp mill of the Gold Prince mine is handling 40 tons daily. Work is to be started at the new 500-ton mill at Animas Forks.

The Sound Democrat claims and millsite at the head of Mastodon gulch, near Silverton, have been sold to J. B. Lazell and J. W. Walker for $100,000 by J. James and W. G. White.

San Miguel County.

It is reported that Alex. Greig will resume work at the Nevada mine, near Ophir.

Tests of vanadium-bearing rock found on the San Miguel river, near Newmire, are to be made by the Vanadium Alloys Co., with office at 25 Broad street, New York City. W. T. Rynard, manager, and H. A. Hillman have been at Telluride examining the deposit. It is stated that a 25-ton mill is to be built to concentrate the product.

Summit County.

The Wachter & Weaver property in McCullough gulch, near Breckenridge, is being developed by a tunnel.——F. A. Yauger, manager of the Beaver Creek Gold Mines Co. at Alma, has been getting machinery to put the Lucky mill at work on ore from the Beaver Creek Co.'s property.——The Wild Irishman, on Glacier mountain, Montezuma, and operated under the management of T. Connors of Leadville and Kokomo, is being developed by running a lower tunnel which is to be 2000 feet in length. A vein of ruby silver ore has already been cut.——Superintendent E. W. Fairfield reports the mining situation in the Silver Wing mine at Montezuma as good.

E. T. Brooks has completed his 1000-foot contract on the French Creek tunnel, in French gulch, for Lennox, Evans & Co. The tunnel has been driven 1358 feet.—— The Mary Verna and North American properties at Frisco are to be equipped with air compressors and power drills and the tunnels driven 3000 feet.

Teller County.

It is reported that a new ore shoot is being opened up on the 12th level of the Last Dollar mine on Bull hill, Cripple Creek.——A new cyanide plant is being put up at the Des Moines Co.'s property on Bull hill.——The new compressor has been started at the Blue Bird mine on Bull hill.——The Portland Gold M. Co. has opened up a new vein at a depth of 1350 feet, in the No. 3 shaft, located on the crest of Battle mountain, Cripple Creek. ——The experimental mill erected at Stratton's Independence has been closed after one year's service. The mill was built to test the low-grade ore in the great dump by the Cassell process. It is reported that the low-grade ores of the dump, which approximate 1,000,000 tons and possibly average $4 per ton, can be treated at a net profit.

The Winner Gold M. Co. has put in a 20 H. P. hoist, with blacksmith shop on its Winter Hill holdings near Midland. The company has seventy acres, on which development work is being done. A. M. Levy is general manager.——Edward Mayfield has leased the Van Fleet sampler, near Goldfield, and will probably run it as an independent plant. He proposes to use cyanide. The closing of the Standard mill of the United States R. & R. Co. at Florence has caused anxiety as to what will become of the large body of ore that was formerly shipped to that plant.——The cyanide mill built by the Exposit on Co. at the Los Angeles mine, on Bull hill, Cripple Creek, is now in operation, fifty tons of ore being treated daily. The plant has three 150-ton tanks and in time the full capacity of the mill will be treated. Larger crushing machinery is to be put in when necessary.

IDAHO.

Blaine County.

Vancil & Grimm have struck ore in their claims, 8 miles west of Hailey.——A vein of galena has been cut in the Oswego mines, near Hailey, by Superintendent Weaver.

Idaho County.

The Hogan mill at Oro Grande is being enlarged.

R. W. Purdun, general manager of the Sunnyside mine at Roosevelt, and Superintendent Treewick have been making tests of the ore preparatory to putting in a cyanide plant.——The Standard ore is increasing in value as the work goes on. This company will soon have its mill in.——The machinery for the Twentieth Century mine is coming in to Roosevelt.

W. O. Brown, manager of the Concord mine in Buffalo Hump, reports that good work is being done in the Hump this season and some excellent ore is being found. Extensive development work is being done on the Concord property, with good results.

Lemhi County.

W. S. Burton, superintendent of the Gold Dust mines, near Leesburg, intends remodeling the mill.

Shoshone County.

The Benton M. Co., of Burke, is developing claims on Gorge gulch. The last 50 feet of work on the No. 3 level has cut a shoot of good concentrating ore. The No. 3 level is in on the middle vein 900 feet, having a vertical depth of 400 feet. This level will ultimately gain a depth of 1000 feet on the edge. The principal owners of the Benton Co.'s stock are: John Callahan, of Burke, president and manager; J. F. Callahan, of Burke, Theodore Anderson, lessee of the Rex mine, and W. Smith, of Portland, Oregon. The mill equipment consists of one rock crusher and three sets of rolls, eight Wilfley tables, a magnetic separator, separate ore bins for lead and zinc concentrates and settling tanks. The mill will fine crush all the ore for the purpose of getting the best separation possible. None of the feed will pass the rolls until it can pass through at least a 30-mesh screen. This fine crushing and the electric separator are the features of the mill and its object is to produce both lead and zinc concentrates. It will have a capacity of 100 tons of ore per day. Were it not for the desirability of separating the zinc and the lead no milling would be necessary, as the ore is all high in either lead or zinc sulphides, as well as in silver. It is to treat ore from the Granite mine.

Shortage of water is already doing some damage on Nine Mile. The Rex mill has been closed temporarily this week on account of it. A fair amount of rain would supply enough water, and this is the only probable source of supply. T. Anderson, the lessee, states that a few men will be employed at the mine doing development work.——While the mill at the California and Black Cloud has not been materially affected as yet, there is no surplus of water.——The new mill of the Success Co., to

have been started by August 1, has very high pressure and it is hardly possible for the water to get so low as to interfere with its running.

At the Frisco mine at Gem there are three parties working leases in the upper levels and shipping five cars a month of ore and concentrates. Gus Ehrenberg employs ten men steadily and for the past four months has been averaging 150 tons of ore and concentrates a month from his workings. The mill is under lease to him and his plan of operation is to accumulate enough milling ore for a three days' run and then start up the mill and keep it going until he has cleaned up. The other two leasing outfits do not mill any of their ore. All they extract is sorted by hand and such as is not high enough grade to ship is left in the stopes or on the dumps.

MICHIGAN.

Houghton County.

President W. A. Paine of the Copper Range Con. says that the Champion does not contemplate the opening of a fifth shaft this year. The four shafts now developed —B, C, D and E—provide all of the ground that is needed at present. It is impossible to say when shaft F, to the south of E and toward the Globe property, will be started.——The Mass mine railroad extension to shaft C is being connected to the Mineral Range Railroad. The Mass has been shipping rock regularly from shaft C. This rock is hauled down the heavy grade by team to the railroad connections at shaft B. The length of the railroad extension will be 4000 feet. Shaft C is opened to a depth of 600 feet. The shaft is sinking on the Butler lode, but through crosscuts the Knowlton lode is also being developed. At shaft A sinking is now progressing below the fifteenth level and at B below the sixteenth level.

The Isle Royale exploratory drift on the Portage lode is 600 feet long at the 800-foot level. It equals the showing made below the 1000-foot level in crosscuts from No. 1 shaft. No. 2 shaft is down 1800 feet, sinking in copper above the mine's average. Section 11 shaft is 150 feet deep; 900 feet of drifting has been done. The shaft is bottomed in good ground. The Isle Royale mill is treating 650 tons daily. As yet the management has no plans for the Baltic lode.

MISSOURI.

Jasper County.

The Joplin News-Herald reports that the Maud E. mill at Chitwood, belonging to B. L. Van Hoose and S. J. Chitwood of Carthage, has been started.——The Boston-Springfield mine, on the Gordon ground, has been leased to a new company and the mine will be reopened. New pumps will be put in and the work of draining the ground begun.——Two mills are to be torn down and rebuilt—the Big Kate at Neck City and the Atlas at Carterville. The Big Kate is also to be moved onto the Cockleburr mine, on the Reliance lease, and the Atlas will be moved to the mine of the General Lead & Zinc Co. at Prosperity.——The Coil Co. are sinking their shaft near the Bumble Bee. J. J. Wickham is manager.

MONTANA.

Deer Lodge County.

In the Moose Lake mining district, 38 miles west of Anaconda, the Moose Lake M. Co. is opening up its claims. The company has a 10-stamp mill and a 40-ton cyanide plant is to be added. They own 1000 inches of water in Carp creek and intend to generate power with the flow.——Ore is being shipped from the Abe Lincoln, a claim adjoining the property of the Moose Lake.

Granite County.

Smart Creek mining district, near Philipsburg, is attracting attention since the bonding of the Red Metal and Copper State properties to Butte people, who are proceeding with development. The Eagle, owned by U. F. Hughes, is also being worked. A tunnel has been run 250 feet to cut the vein, upon which a shaft about 125 feet had been sunk.——J. Bush is also developing the Nancy Hanks in the same district.——Sherr & Looney are working the Nonparell in the Princeton district with a small force. The Nonpareil is a lead-silver proposition and ore will be shipped to the smelter at Pen d'Oreille, Idaho, for treatment. They have been working the mine through new shafts, but the old one, which is down 400 feet, is being retimbered and the hoisting plant at the shaft will be put into working shape.——At the Albion, above Princeton, Wagoner and his associates are developing. It is reported that a mill is to be put in. ——The Royal Gold is again shipping. The property is owned by Conrad Kohrs and others. The stamp mill now on the property is being put in repair and will soon start running on good milling ore.——The Scherr Bros. are working the Old Witch mine, in the Princeton district, under a bond and lease.

Jefferson County.

The Apollo claim, near Basin, owned by H. L. Frank, of Butte, is being worked by D. Driscoll under a bond and lease. He has several men working on the property and has built ore bins at the side of the road where it can be handled conveniently by the teams. The ore is free milling gold and is to be hauled to the 10-stamp mill on Basin creek, which is being repaired.

Madison County.

A. C. Sanders, superintendent of the Mammoth M. & P. Co., is putting in new machinery at the mine at Mammoth.

Silver Bow County.

The mill of the Montana Zinc Co. in Butte is ready for work, the improvements and repairs commenced a few weeks ago being completed. During the suspension a new revolving dryer was added and repairs made.

About a year ago changes were made in the Washoe smelter, to enable the plant to handle the fine ores and flue dust in a more satisfactory manner than the one in use. Under the old methods the contents of the ore cars were dumped bodily into the furnaces. The heavy ore smelted easily, but the fine ore collected at the bottom of the blast furnaces and it took a great deal of blast and heat to make it yield. In the ordinary blast furnace in use in Montana this heavy blast that was necessary to get a perfect pour caused the generation of large bodies of gas, which the company was unable to use. Reverberatory furnaces were installed which were confined solely to the handling of fine ores and flue dust. This enabled the blast furnaces, running on coarse ores alone, to increase their capacity largely and make an increase in the amount of product handled by each furnace of about 40%. In this way the Washoe avoided the briqueting of its flue dust, which is now merely put into the reverberatory together with the fine ores which they treat. Besides, there is much less of the flue dust in the large stack at the end of each day's run than was the case when the ore was treated unsorted. By running the coarse ore alone less fuel is required and the fusion is made more rapidly than is the case when a higher temperature had to be employed. Coke is used exclusively in the blast furnaces, while coal is used in the reverberatory. This makes a great saving to the company, as the gases which are generated by the coal and the ores are conducted in ordinary pipes under the boilers and used for the generation of steam for all the varied purposes of the company. The saving thus effected amounts to from 35% to 40% in the fuel charges of the furnaces. While the item of flue dust has been decreased, the direct method of handling this product represents a saving of $1000 a day. The changes that were made to effect these savings represented an outlay to the company of a little less than $15,000, and their total effect is that they have reduced the treatment charges 40%. The only briqueting now done at the Washoe is in connection with the saving of the slimes.

NEVADA.

Elko County.

A large pump has been put in at the Dexter mine at Tuscarora and the lower levels are being drained.—— Work has started on the Commonwealth and Queen, recently sold to New York and Denver people.

Esmeralda County.

Another attempt is to be made to extract the values from the 400,000 tons of rich tailings that lie on the dump of the old Bellville mine, 10 miles from Sodaville.

Drifts are being run both ways from the 350-foot level of the Florence mine at Goldfield. The copper values are said to be increasing. A station has been cut and a drift is being run southeast at the 310-foot level of the Dixie at Goldfield.——On the Honsinger lease on the February at Goldfield the shaft is being sunk 100 feet from the 100-foot level. A gasoline hoist is in use.——It is reported that the Bonnie Clair M. & M. Co. will put in a stamp mill and cyanide plant in the Tokop district.

Lincoln County.

Ore from the Chiquita mine at Good Springs is being milled at the Keystone mill at Sandy.——It is reported that Byron, Rupe & Armstrong will put in a mill to treat ores from the Red Cloud. A gasoline hoist has been put in.

In Pioche canyon landslides have buried a stamp mill belonging to the Southern Nevada Gold Ore Co., imprisoning two miners, who were rescued in an unconscious condition and taken to Las Vegas. They are not thought to be fatally injured. Many mining companies suffered heavy losses, but the railroads were the greatest losers.

C. E. L. Gresh, manager of the Black Hawk M. Co. of Eldorado canyon, has opened rich ore on mine No. 2 of the company's property, comprising the Wedge, Rand and Honest Miner claims. —— The Cyrus Noble main shaft at Searchlight is down 402 feet and sinking for the 500 level is being pushed. Water was struck at 351 feet. As soon as sufficient water is developed a mill will be put on the property.

Lyon County.

The Eureka mill, one of the oldest and largest reduction works on the Carson river, has been sold to J. E. Monroe of Reno. The deal embraces the mill building and all real estate, consisting of 640 acres, a railroad 2 miles in length and all its rolling stock, together with the cyanide plant.

Nye County.

It is reported the Congress M. Co. will start development work at the old Chespa mine, near Johnie, with John Ross as superintendent. H. Ramsay is general manager.

Washoe County.

Big strikes are said to have been made in the White Horse mining district by DeWitt Bovee, who is driving a long tunnel on the Ora group, ½ mile west of Olinghouse.

OREGON.

Baker County.

The 10-stamp mill at the Tabor fraction property at Bourne is almost completed. A. G. and R. H. Hanauer of Spokane, Wash., are interested. The owners say they intend to double the capacity of the mill and put in a cyanide plant for the treatment of tailings next winter.

Considerable development is being done in the Eldorado section south of Tipton. D. B. Stalter, manager of the Heppner M. Co., is making arrangements to put in a stamp mill to treat ore from the Mayflower group.—— Near Greenhorn, the Weston, owned by W. H. Gilbert and H. Shoemaker, has a shaft 50 feet deep. Work was stopped owing to influx of water. Now a hoist and pump have been put in. Sinking has begun again.

Grant County.

The owners of the Equity mine in the Quartzburg district have put on a larger force and contemplate building a 75-ton mill and hoisting plant. Much work is being done on the four levels and good ore reserves are being established.

Josephine County.

Considerable work is being done in the Mule Creek district, near Marial P. O. Mendenhall & Co. of Gold Hill will put in a 3-stamp mill at the Mendenhall mine, on the west fork of Mule creek, 2½ miles from Rogue river. T. Billings has charge.——A. E. Frye, F. Frye and E. A. Ruth have sold their gravel mine on Rogue river, 3 miles below Mule creek, to Eastern parties, who will put in two hydraulic giants to be supplied with water from East creek by a 26-inch pipe, 1½ miles long. ——At Big Bend a company of Minneapolis and St. Paul capitalists have bought 230 acres of placer ground and have had men preparing for a hydraulic plant. The water will be brought 4 miles, from Foster creek. The stream will be 1½ foot deep and 4 feet wide, and the water will go to two No. 4 giants under a head of 300 feet.—— H. J. Mattoon has been working the Mark placer at the mouth of Mule creek.——Manager Frank Fowler, of the Gold Pick mine, on Bolen creek, near Grants Pass, is putting in a 3-stamp mill and water wheel. A ditch, ¾ mile long, has been completed that will bring 250 inches of water from East Bolen creek and deliver it to the wheel under a head of 225 feet. This will furnish power for a large mill and, Bolen creek being fed from the mountains, the water supply will continue during the summer months. Lumber for the mill was hauled from near Selma to Sucker creek and packed in over the trail.——A. W. Gilbert and C. E. Platts are developing copper claims on Bolen creek.

Lane County.

The Great Northern Dev. Co., which bonded the Great Northern group, Blue River district, east of Eugene, from the Great Northern M. & M. Co. for $45,000, has taken up the bond. The 4-stamp mill on the property has resumed work. The new aerial tramway has been completed. It is 1200 feet long. The new water power plant and canal have been completed and the plant will be run by water with steam auxiliary.

SOUTH DAKOTA.

Fall River County.

The Black Hills Fullers Earth Co. has been incorporated to work a deposit 12 miles southeast of Hot Springs. The deposit is a cretaceous stratum in black lake bed shale. The earth is of dark blue slate color. E. S. Kelley of Hot Springs is president.

Lawrence County.

The property of the Minnie M. Co., which consists of a number of claims between the property of the Golden Crest and the Gilt Edge Maid, near Galena, has been leased and bonded to Fritz Weber, who intends to sink a two-compartment shaft.

The Victor G. M. & M. Co., working claims 4 miles east of Deadwood, have driven their 400-foot tunnel 150 feet. I. N. Lawrence is general manager.——The Mariposa Co. at Mystic, under the management of J. Wise, has put men on a long crosscut tunnel.——It is reported that work is to be resumed at the Clover Leaf mine in September.

UTAH.

Beaver County.

D. P. Rohlfing, manager of the Frisco Contact and Lulu properties at Frisco, has put a blower in the Frisco shaft to improve the ventilation. The shaft is down 285 feet. The shaft will be continued to the lime in case it is reached within 500 feet, and, if not, a crosscut will be made to it at that depth. At the present time over 800 gallons of water per day is making. Water is valuable on account of its scarcity. At the Lulu drifting is progressing on the 400-foot level.

Juab County.

Three shifts are sinking the shaft at the May Day mine, at Eureka, from the 300-foot level to the 500-foot level, after which the ground will be explored.——The property of the Martha Washington M. Co. has been sold to J. M. Taylor of Silver City.

The shipments from Tintic district for week ending July 29 were: Centennial-Eureka, 50 carloads; Gemini, 10; Bullion-Beck, 5; Yankee Con., 5; May Day, 2; Eagle & Blue Bell, 13; Swansea, 7; Eureka Hill (leasers), 4; South Swansea, 2; Victoria, 7; Ajax, 2; Carisa, 2; Mammoth, 21.

Salt Lake County.

Manager W. C. Orem of the Utah Apex M. Co., operating at Bingham, reports the lower tunnel in 300 feet. They intend to run 1000 tons of mill ore through the custom plant owned by E. A. Wall as soon as the mill can take it. Now it is running on ore from the Phœnix mine.

The Bingham Bulletin publishes the following data on Bingham mines:

Mine—	Men.	Tons.	Payroll.
Highland Boy	350	850	$32,000
Yampa (mine and smelter)	425	425	25,000
Utah Copper (mine and mill)	400	700	20,000
United States	300	425	12,500
Bingham Con	300	500	20,000
Boston Con	120	250	7,000
Bingham-New Haven	50	50	5,000
Ohio Copper (mine and mill)	95	225	6,000
Utah-Apex and Red Wing	60	45	4,500
Fortuna	45	50	3,500
Phœnix	60	100	7,500
Silver Shield	22	....	2,100
New England	20	25	1,500
Butler-Liberal	20	....	1,500
Other properties	150	25	10,000
Totals	2,417	3,670	$158,100

The Congor mine in Bingham is to be started up again after an idleness of several years, during which the lower workings were allowed to fill with water. G. G. Hall, the manager, has men putting in new equipment. A new hoisting plant has been ordered and is on the ground, and new boilers are being put in to replace the old ones. The lower workings of the mine are reached by way of an incline shaft 500 feet deep.

Tailings operations along the creek below Bingham are becoming important. The largest is that of Rogers & Lerwill at Lead mill. This is equipped with a device of Rogers' invention, which consists of an endless belt and designed to treat slimes. The owners have been troubled with a shortage of water.——Brooks & Locke have a plant above the smelter, consisting of two tables, two jigs, canvas tables, electric motor, etc.——Shackelford & Flig are putting in a plant above Lead mill. Their equipment consists of a Wilfley table, two jigs and a gasoline engine.——Manager H. M. Crowther, of the Continental Atlas mines at Alta, reports that his company

has begun concentration of molybdenum ores. While the equipment for the handling of this class of ores has not been perfected, Manager Crowther says the product being obtained has a value of $200 to the ton. With the existing facilities it is said that one ton of molybdenum concentrate can be turned out daily.

Uinta County.

O. Wilkins, who has spent several months in Vernal, reports placer mining at Green River, near Jensen, in the newly discovered district, steadily going on, although the high waters of the spring and summer have interfered with the work. Men are taking out $1.50 to the square yard with rockers.

WASHINGTON.

Ferry County.

Reports from Meteor camp, on the south half of the Colville reservation, tell of greater activity than for two years. The Meteor Co. is working seventeen men, and arrangements are being made to put on a larger force. A tunnel is being driven to crosscut the vein. A full crew is working on the Nonparell. This company is driving a long tunnel to tap the lead. It is reported that the shaft of the New York is in good ore. The Stray Dog is preparing to continue work.

Skamania County.

R. C. Lange, manager of the Spirit Lake Power & M. Co., which is operating near Spirit lake, intends to drive a 3000-foot crosscut to open veins and raise to the surface. The power plant and drills are to be put in.

Snohomish County.

(Special Correspondence). — Trustees have inspected the Bonanza Queen mine at Monte Cristo. The raise of 1000 feet from the crosscut to the old workings is nearly finished. Material for an aerial tram, 1 mile long, from the crosscut to the Monte Cristo railroad, has been purchased and will be put in.——The old slag dump at the American Smelting & Refining Co.'s Everett plant is again being run through the furnaces to extract the values left by previous treatment.——F. W. Peabody's Sidney mine at Monte Cristo is shipping ore to the Everett smelter. A pump has been put in to keep the mine dry until a crosscut to tap the vein at a depth of 180 feet is completed. The crosscut will be 500 feet in length. Sinking and stoping will be continued.——J. Pecalo, superintendent of the Lucky Day M. Co., has discovered a vein on Silver Tip mountain west of Monte Cristo, carrying a high grade of native copper.——A new air compressor is being put in at the Packard M. Co.'s mine at Monte Cristo.

Monte Cristo, Aug. 1.

Stevens County.

W. Connelly of Spokane has interested an Illinois company in the New England claims, 5 miles from Northport, on Deep creek, opposite the Last Chance. The New England is a zinc producer, and the Illinois people have taken a bond at $20,000, providing for two semi-annual payments and a year's continuous work. The owners are L. Cook, B. Stout, J. Johnson and I. Guzelius.——The owners of the Galena Queen, near the New England group, are sinking on the ledge. A depth of 60 feet has been reached. C. E. Plumbtree has the contract for sinking.

Whatcom County.

The Bonito G. M. Co. has been formed with W. P. Bell, of Everett, president; E. Lenfest, of Snohomish, vice-president; J. V. Bowen, of Snohomish, treasurer; W. Whitfield, of Snohomish, secretary; A. W. Hawkes, of Snohomish, general manager. The company will work the Eureka mine, in the Slate Creek district, and intend to start the plant on October 1. The company has a 10-stamp mill and a 2000-foot tunnel with 2600 feet of tram.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Boundary District.

For the week ending July 29 the Boundary ore shipments were: Granby mines to Granby smelter, 13,630 tons; Mother Lode to British Columbia Copper Co.'s smelter, 2272 tons; Emma to Nelson smelter, 418 tons; Oro Denoro to Granby smelter, 33 tons; Last Chance to Nelson smelter, 20 tons; total for the week, 16,373 tons; total for the year to date, 523,217 tons. Boundary smelters treated ore the same week as follows: Granby smelter, 13,850 tons; British Columbia Copper Co.'s smelter, 3960; total for the week, 17,810 tons; total for the year, 535,742 tons.

Work is being pushed on the new power plant at Bonnington Falls, on the Kootenay river, to supply power to mines in the Boundary district. Power will be transmitted from this plant as far as Phœnix, a distance of 80 miles.——Shipments are starting from the E. P. U., near Greenwood, as repairs to the tramway have been completed. Drifting is going on at the 200-foot level. Three shifts of men are at work in the main shaft of the Crescent, which is down 80 feet, and will be deepened to the 100-foot level, when drifting will be done.

Regarding additions to the machinery, plant and other equipment of the Granby Con. M., S. & P. Co.'s mines at Phœnix and smelting works at Grand Forks, the British Columbia Mining Record says that complete equipment, at a cost of $75,000, of a terminal for the branch of the Great Northern railway, entirely separate from that in use by the Canadian Pacific railway, has been provided, this including receiving ore bins, ore crusher with a capacity of 150 tons per hour, crushed ore bins and facilities for loading about 1000 tons of ore on a train of thirty-five cars in twenty-five minutes. No. 3 tunnel, which is about ¾ mile in length, has been double tracked and equipped with a 75 H. P. electric motor and 10-ton steel ore cars. The new main double-compartment incline shaft, which is being sunk to the 500-foot level, is nearly completed. A 200 H. P. electric hoist is to be put in. Balanced skips, each of a capacity of three to four tons, will be used. The size of shaft and capacity of equipment will admit of hoisting 3000 tons in two 8-hour shifts. The two 48x210-inch water-jacketed furnaces, now being put in at the company's smelter, are fitted with twenty-four tuyeres on each side. The automatic charging cars are the invention of the manager, A. B. W. Hodges. These cars are side dumping and each is divided into four compartments. This arrangement insures the proper distribution of the ore in the furnace, the necessary proportion of "roughs" going toward the center. Two of these cars, coupled, are run into each of the ordinary sized furnaces on side rails. For the larger furnaces three will be used. The cars are moved between bins and furnaces by electric motors. All slag is dumped hot, being handled from the furnaces in 6-ton pots. The new double-cylinder blowing engine for the converter room, in which there are two converter stands and ten shells, has a capacity of 6000 cubic feet of air per minute, thus bringing the total available air up to 10,000 cubic feet. A 300 H. P. motor operates the new engine. An automatic slag conveyor, similar to that in use at the Washoe smelter, Anaconda, Mont., elevates the converted slag. A second mixing mill, for converter linings, has been added. The new Connersville blower, driven by a 300 H. P. electric motor, has a capacity of 30,000 cubic feet per minute, as compared with the 12,000 cubic feet capacity of those previously installed. An addition of 800 feet has been made to the dust chamber, giving a total length of 2000 feet. Machine shops and blacksmith shops have been improved.

Cariboo District.

R. H. Hanauer of Spokane, Wash., and A. G. Hanauer have acquired a controlling interest in the Bear hydraulic mine, 11 miles from Barkerville, and are preparing to equip the property. Experimental work on the Bear has extended the channel for a width of 350 feet with both rims. The gravel is free, containing comparatively little clay. B. A. Lascelles is directing the work. Two ditches are being constructed. One of these will bring in the water from Cunningham creek, a maximum flow of 2500 inches being obtainable for ground sluicing. The second ditch will carry water from Antler creek, 3000 inches being available from this source for the two giants the owners will put in immediately. A cableway will be constructed to handle boulders and a sawmill set up on the property.

East Kootenay District.

The tests of Michel coal by the C. P. R. proved satisfactory and sustained the convictions of the coal company officials as to the quality of their coal for steaming purposes. The ordinary evaporative power of coal in the practical working of locomotives is from six to seven pounds water evaporated to one pound coal consumed. The tests conducted by Mr. McEvoy showed an evaporative power up to 10.6 pounds of water to one pound of coal consumed. The most interesting test was on the local express between Winnipeg and Brandon, with twenty stops between those points. It was found that 3820 pounds of coal was sufficient to make the trip of 137 miles. The Michel collieries, 23 miles northeast of Fernie, are operated by the Crows' Nest Pass Coal Co., R. G. Drinnam general superintendent.

Nelson District.

The Dundee M. Co. has decided to put in a compressor at the Dundee mine, near Ymir, and also to build a 5-stamp mill. A 140-foot tunnel has been driven into the mountain and better indications are reported. T. B. Sumner and E. Husted of Everett are president and secretary.

Rossland District.

The White Bear mine, which closed down on account of a shortage in its motive power on May 23, will resume operations on August 1. F. Demuth, manager, says that work will be recommenced on the rich shoot of ore on the 700-foot level. The drilling at first will be done by hand, awaiting the arrival of the 400 H. P. motor to furnish power for the mine and the concentrating mill.

The tonnages of ore shipped from and crushed at the Rossland mines for the week ending July 29 and for the year to date were as follows:

Mine.	Week.	Year.
Le Roi	1,975	72,106
Le Roi (milled)	210	720
Center Star	2,310	56 190
War Eagle	1,500	40,370
Le Roi Two	60	4,462
Le Roi Two (milled)	....	4,330
White Bear	....	1,100
White Bear (milled)	....	2,220
Jumbo	3,000	5,829
Spitzee	60	4,539
Velvet-Portland	....	1,977
Gopher	....	60
Homestake	....	30
Lily May	....	60
Totals	6,415	195,193

At the Center Star at Rossland electric haulage is to be substituted for man power in transporting ore from the mouth of the shaft to the bunkers and the waste from the shaft to the waste heaps. Workmen are strengthening the trestles so that they may be able to bear the increased weight. Horse power was tried for a time, but the horse used was killed.——E. Stevenson of Rossland has leases on the Crown Point, Hidden Treasure and the White Swan claims, on the slope of Lake mountain, 2½ miles southeast of Rossland. He has ten men working.

Slocan District.

There are 250 men working in the mines around Sandon. The leasing system has helped the camp. The Buffalo claim and the Lone Bachelor have been opened up.——At the Payne mine Walter Smith is working fourteen men and shipping ore.——The Slocan Star and the Lucky Jim are shipping.——The Hewitt group, 3½ miles southeast of Silverton, has been bonded to W. S. Logan of Nelson for $250,000.——At the Jackson mine, 5 miles from Whitewater station, the mill is running two shifts and turning out an average of fifteen tons of zinc and two tons of lead per day. The zinc is being piled up, there being 400 tons on hand ready for magnetic separation.——At the Last Chance eleven men are employed and development is proceeding with good results. Ore is being sent down daily.——The American Boy mine, near Cody, is working twelve men and Manager T. McGuigan expects to increase the force as soon as the workings dry out.

West Kootenay District.

W. F. Henderson has organized the Gold Park M. Co. to operate the Marquis & Gilbert properties at Poplar. The company will begin work at once.——It is reported that a mill is to be put up at the Swede group to treat ore from the recent discovery.

MEXICO.

Chihuahua.

Heffron & Piper have a 7-stamp mill on their Dos de Abril mine, 15 miles from Dolores, and expect to start the amalgamating mill August 15.——The Tres Amigos G. M. Co. is working mines at Guaynopa. B. L. Croff is president and general manager, and Murray Lee, superintendent of the mines.——The Watterson Gold, Ltd., at Ocampo, has received all of the material for its cyanide plant and is expected to have it ready for operation in two months.——At the Pinos Altos mines, in the Ocampo district, the work of remodeling the old 55-stamp mill is progressing well, and it is expected that twenty stamps will be in operation within a month.——At the Concheno mines at Concheno the mill is ready to be started now that the main shaft, 600 feet deep, has been enlarged from two to three compartments. Superintendent Murray enlarged the shaft and timbered it up in six weeks. The work of increasing the capacity of the cyanide plant from 60 to 100 tons daily is to be commenced.——At the Cruz mine, near Ocampo, a steam hoist has been put in by T. Williams of Chihuahua city, superintendent.

Guanajuato.

A cyanide plant, a stamp mill of 250 tons capacity, six pumps and other machinery are being put in at the Guanajuato R. & M. Co.'s plant. The machinery is to unwater the Valenciana mine. Joseph Slater and Orrin Thacker of Columbus, Ohio, associates of C. L. Kurtz, president of the company, are at the mines.

Jalisco.

John McGrath of Boston, Mass., formerly manager of the Buena Vista mines at Tepic, and F. J. M. Rhodes have surrendered their bond and lease on the Zuloaga mine in the Bolanos district.——T. C. Myers has purchased the interest of H. K. Meyers of Philadelphia in the Culebra mines, near Etzatlan, and will develop the property.——A steam hoist, capable of raising 500 tons of ore daily, has been purchased by Ferdinand Sustersic, manager of the Ampero M. Co. at Etzatlan, and will be put in the old Santo Domingo shaft of the Santo Domingo mine. The shaft will be made three compartment. The experimental reduction plant, near the Santo Domingo mine, is nearly finished. The company has on hand about 1,000,000 tons of milling ore, and as soon as the exact character of the treatment necessary is determined, a reduction plant with a capacity of 100 tons daily will be built.

Commercial Paragraphs.

BAILEY-SMITH MACHINERY CO. is a newly incorporated company, with office and salesroom at 91 Fremont street, San Francisco, Cal.

THE Independent Pneumatic Tool Co. has bought the plant of the Aurora Automatic Machinery Co. at Aurora, Ill., and are making a general line of pneumatic tools. Their offices are in the First National Bank Building, Chicago, with an Eastern branch at 170 Broadway, New York. John F. Brady is president.

ORDERS have been received by the Westinghouse Electric & Manufacturing Co. of Pittsburg, Pa., from Nelson Morris & Co. for nineteen type CCL induction motors, varying in sizes from 5 to 50 H. P. and totaling 410 H. P., and for eight motors of the same type from the Decatur Car Wheel & Manufacturing Co., Birmingham, Ala. The Illinois Steel Co. has ordered eighty direct current motors, having an aggregate capacity of 3920 H. P. The Hawaiian Electric Co. of Honolulu has contracted for two 1200 K.W., three-phase, 2200-volt, engine type generators, two 125 K.W. exciters and seven 500 K.W., oil-insulated, self-cooling transformers.

THE Cameron Steam Pump Works of New York City send two celluloid bookmarks, printed in colors from appropriate designs, substantial and admirable for the use for which they were intended. In each they have utilized their trade mark, an acorn-shaped air chamber, to furnish the base of the design, which is printed in black and on which in one design is shown a Scottish bagpipe player in full regalia, wearing the Cameron plaid and piping lustily as he marches across the heather. In the other design is shown in colors a winsome lassie, wearing the Cameron plaid and dropping a graceful courtesy, and the phrase, "Thank you kindly;" both are veritable works of art.

COLORADO IRON WORKS CO. of Denver, Colo., report the following orders: Carload of jackets for the Mazapil Copper Co., in Mexico; slag pots, ladles and moulds for the Ohio-Smelting Co., in Colorado; one 42x160 silver-lead blast furnace for the St. Joe Lead Co., in Missouri; two carloads of slag trucks and bowls for the Cananea Con. Copper Co., in Mexico; accessories and equipments for reconstruction of furnace for the Compania Minera la Quimica y Anexas S. A., in Mexico; additional equipment for the Minas Ferrocarril de Santa Maria de la Paz y Anexas, in Mexico; one 42-inch circular copper furnace and equipments for the Ohio-Mexican Mining Co., in Mexico. Milling orders are placed as follows: Machinery and equipment for the Hercules Mining Co., in Idaho, consisting of thirteen C. I. W. impact screens, two sets 36x16 Humphrey crushing rolls, etc.; one impact screen to the Annie Laurie M. Co., in Utah. Mining accessories: Ore cars, buckets, etc., to the London M. & R. Co., in Colorado, and one Bartlett simplex concentrator to the Denver Ore Testing & Sampling Co., Colorado.

Books Received.

Twenty-Third Annual Coal Report of the Illinois Bureau of Labor Statistics, 1904, from David Ross, Secretary, Springfield, Ill.

Report of the Royal Commission on the "Ventilation and Sanitation of Mines of Western Australia" contains the results of an exhaustive study into the subject. It is published by the Department of Mines, Perth, W. A., for 5 shillings.

"Gold and Tin Dredging Practice," by H. L. Lewis, is a pamphlet made up of republished articles on recent dredging practice in Australia, New Zealand and California. It is published by the Mining Journal, London, Eng., and will be sent by the MINING AND SCIENTIFIC PRESS for 50 cents.

Much of the disease of the average mining camp might be prevented by observing the precautions given by H. A. Bashore in "The Sanitation of a Country House." It deals with the location, hygienic construction, water supply and waste disposal. The treatment is practical and applicable to either permanent or temporary camps. It is published by John Wiley & Sons, New York City, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $1.00.

"Methods and Costs of Gravel and Placer Mining in Alaska," by C. W. Purington, Bulletin 263 of the United States Geological Survey. This contains an account of methods of prospecting and operating placer mines under adverse conditions. The material presented is of the utmost practical value as a guide under similar conditions, and should aid in opening up the country. The illustrations are particularly good. The whole represents a judicious compilation of practical data.

"The Copper Handbook," Vol. V, 1905, by H. J. Stevens, is devoted to the history, uses, terminology, geology, geography, chemistry, mineralogy, finances and statistics of copper. The book describes the copper mines of the world, 3489 in number. In the five years of its issue "The Copper Handbook" has grown from a strictly local publication, the first issue having been devoted exclusively to Lake Superior mines, to a standard reference book. The data given is essential, concise and apparently reliable. It is published by H. J. Stevens, Houghton, Mich., for $5, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS on receipt of price.

Vol. XXIV, No. 7, "Proceedings of the American Institute of Electrical Engineers," contains the following papers and discussions: High-Power Surges in Electric Distribution Systems of Great Magnitude, by C. P. Steinmetz; Water Powers of the Southeastern Appalachian Region, by F. A. C. Perrine; A New Carbon Filament, by J. W. Howell; Alternate Current Machinery—Induction Alternators, by W. Stanley, assisted by G. Faccioli; Note on a Simple Device for Finding the Slip of an Induction Motor, by C. A. Perkins; Notes on the Power Factor of the Alternating Current Arc, by G. D. Shepardson; Eddy Currents in Large Slot-Wound Conductors, by A. B. Field; Data Relating to Electric Conductors and Cables, by H. W. Fisher; An Experimental Study of the Rise of Potential on Commercial Transmission Lines Due to Static Disturbances Caused by Switching, Grounding, by P. H. Thomas; Constant Current Mercury Arc Rectifier, by C. P. Steinmetz; Synchronous Converters and Motor Generators, by W. L. Waters; The Organization and Administration of National Engineering Societies, by J. W. Lieb, Jr.; Light Electric Railways, by J. R. Cravath.

"Civil Engineering," by G. J. Fieburger, professor of engineering United States Military Academy, is designed for the instruction of cadets being fitted for a profession in which the principles of civil engineering are applied daily. As a short course for any one desiring a thorough grounding in these principles the book is admirable. It fully treats stresses, beams, columns and rivets, with both analytical and graphic determination of stresses and effects of fixed and moving loads. Two chapters are devoted to masonry arches, dams and retaining walls, followed by a brief treatise on the pressure and flow of water. The characteristics of timber, metals and stone are treated successively. The general principles of construction of masonry, foundations, bridges, trussed roofs and floors, highways, water supply and sewerage are indicated. While brief, the treatment is concise, logical and easily read. The methods and formulæ given are up-to-date and recognized as standard. With this text and a Trautwine there are few problems that a civil engineer might meet in his practice that could not be solved, even if he had forgotten the first principles. It is published by John Wiley & Sons, New York City, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of $5.

Trade Treatises.

The Searchlight Publishing Co. is organized at 24–26 Murray street, New York, to forward the publishing and advertising interests of manufacturers, publish the "Searchlight," keep the Searchlight information library up to date, and to publish books.

The Bartlett "Simplex" concentrator is illustrated and described in detail in a neat pamphlet from the Colorado Iron Works, Thirty-third and Wynkoop streets, Denver, Colo.

Dividends.

Bunker Hill & Sullivan M. & C. Co., dividend No. 95, $150,000, payable August 4; total paid since Jan. 1, 1905, $2,475,000; total to date, $4,746,000.

Latest Market Reports.

SAN FRANCISCO, August 4, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27¼d (standard ounce, 925 fine); New York, bar silver, 59½c, refined (1000 fine); San Francisco, 59½c; Mexican dollars, 46c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.50; Lake, 1 to 3 casks, $15.37½@15.50; Electrolytic, 1 to 3 casks, $15.50; Casting, 1 to 3 casks, $14.87½@15.12½. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £68 6s 3d spot per ton.

Copper has taken a slight upward turn, showing that the market remains firm under increased summer production. There is said to be practically no floating supply, which will have a tendency to maintain the price at the present figure, if not to increase it. There has been a slight falling off of price in London during the past week, the present quotation, though higher than that of last week, being somewhat lower than that of two or three days ago.

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.42½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £14 ₱ long ton.

SPELTER.—New York, $5.70; St. Louis, $5.18; London, £24 ₱ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $32.80@32.85; San Francisco, ton lots, 33¼c; 500 lbs., 34c; 200 lbs., 34½c; less, 35½c; bar tin, ₱ lb., 35@37½c. London, £151 10s 10d.

PLATINUM.—San Francisco, crude, $18.50 ₱ oz.; New York, ingot, $20.50 ₱ Troy oz. Platinum ware, 75@$1.00 ₱ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ₱ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 18.50c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb, .04c.

NICKEL.—New York, 55@60c ₱ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ₱ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.60; gray forge, $16.00; San Francisco, bar, 3c ₱ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $23.00@$23.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ₱ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ₱ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ₱ bbl.

CEMENT.—Imported, $2.15@2.65 ₱ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ₱ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 12c; Hallett's, 13c; San Francisco, 1000-lb. lots, 11c; 300@500-lbs. 12c; 100-lb. lots, 13c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ₱ set; 14 oz., 40s., 9¾c.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c;. in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c ₱ lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.10@1.20 ₱ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ₱ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ₱ lb.; nitric acid, carboys, 8c ₱ lb.

OILS.—Linseed, boiled, bbl., 64c; cs., 69c; raw, bbl., 62c; cs., 67c; Lucol oil, boiled, bbl., 56c; cs., 61c; raw-bbl., 54c; cs., 59c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 7@8c ₱ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

BONE ASH.—Extra No. 1, 5@6c ₱ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ₱ lb.

MOLYBDENUM.—Best, $2.75 ₱ lb.

CHROMIUM.—90% and over, ₱ lb., 80c.

URANIUM.—Oxide, ₱ lb., $3.50.

MERCURY.—Bichloride, ₱ lb., 77c.

TUNGSTEN.—Best, ₱ lb., $1.25.

PHOSPHORUS.—American, ₱ lb., 70c.

SODIUM.—Metal, ₱ lb., $1.

RED LEAD.—500 lbs. and over at one purchase, ₱ lb. 7¾c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ₱ lb., 2¾@4c.

MAGNESIUM.—Pure, N. Y., $1.60.

BISMUTH.—Subnitrate, ₱ lb., $2.10.

SILVER.—Chloride, ₱ oz., 90c@$1.00; nitrate, 55c.

FIRE BRICK.—Domestic, carloads ₱ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ₱ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR WEEK ENDING JULY 25, 1905.

795,471.—ORE REDUCING APPARATUS—W. T. Armstrong, San Jose, Cal.
795 473.—ANNUNCIATOR—S. B. Bankson, S. F.
795,385.—AIR BRAKE—N. V. H. Bergenheim, Oakland, Cal.
795,487.—PUZZLE—C. B Courtney, Weston, Or
795,584.—GUN SIGHT—C. S. Daniel, Hoquiam, Wash.
795,586.—CATTLE GUARD—W. E. Dement, Blaine, Wash.
795,589.—STOCK FEEDER—J. J. Dowell, S. F.
795,792 —FRUIT PRESS—J. G. Fassett, Pasadena Cal.
795,590.—BICYCLE SUPPORT—E. H. Foster, Baker City, Or.
795,795.—ACCORDION—J. Galleazzi, S. F.
795,700.—MEAT SUPPORT—Heidenreich & Fontaine, Lagrande, Or.
795,610.—RAILWAY SPIKE—B. F. Herndon, Florence, Ariz.
795,702.—WATCH—Hohmann & Kaatz, San Diego, Cal.
795,770.—COAL LOADING APPARATUS—J. L. Howard, Oakland, Cal.
795,619.—WARDROBE, ETC.—J. Jones, Oregon City, Or.
795,707.—PENHOLDER - C. A. Klein, S. F.
795,723.—MUSIC LEAF TURNER—J. McNeil, Oakland, Cal.
795,405.—FENCE POST—C. J. B. Moore, Calistoga, Cal.
795,409.—OIL BURNER—F. E. Nelson, Santa Barbara, Cal.
795,729.—PACKAGING FRUIT—L. Olzen, S. F.
795,417.—EXCAVATING BUCKET—R. H. Postlethwaite, S. F.
795,450.—DRILL—W. D. Rankins, Modesto, Cal.
795,734.—PRODUCING BODIES—J. E. Seeley, Los Angeles, Cal.
795,656.—RAILWAY SIGNAL—W. B. Smith, Redlands, Cal.
795,739.—WATER LEVEL INDICATOR—R. H. Stollar, Longbeach, Cal.
795,667.—PUMPS—W. Wallace, Bakersfield, Cal.
795,323.—ELECTRIC APPARATUS—D. M. Watson, Portland, Or.
795,672 —HARVESTER—F. H. Willms, Knights Ferry, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

ORE REDUCING APPARATUS.—No. 795,471. July 25, 1905. W. T. Armstrong, San Jose, Cal. This invention relates to an apparatus for reducing ores and separating and recovering therefrom the valuable metallic and other ingredients. Its object is to provide a simple portable roasting-furnace for use of prospectors and others The apparatus consists of a tube of uniform diameter threaded at the ends, removable closures for said ends and rendering the tube substantially air tight, said tube having an inner lining capable of being reduced to a carbonaceous form by heat, a condenser and a pipe leading from the tube to the condenser, said tube adapted to contain a body of carbon forming material mixed with ore, and said pipe having the end within the condenser provided with a check valve to prevent backflow into the tube.

DEVICE FOR PACKAGING FRUIT AND THE LIKE —No. 795,729. July 25, 1905. L. Otzen, San Francisco, Cal. The object of this invention is to provide an integral and continuous former and means by which such a former may be removed from the fruit without hinges or joints. It consists in a fruit pressing device, a box with open top and bottom and a pressure plate fitting therein, a plunger and a platen movable therewith, a guide by which the box is alined with the press mechanism, means for transmitting pressure from the plunger to the pressure plate in the box, means for lifting the box after compression has been completed, and springs acting between the plunger and pressure plate to hold the latter down while the box is raised.

COMBINATION CLOTHES RACK, WARDROBE AND BATH CABINET. —No. 795,619. July 25, 1905. John Jones, Oregon City, Or. The object of this invention is to provide a light, simple, portable device that can be easily adapted as a clothes rack, a wardrobe, or bath cabinet, which can be set up anywhere, and which can be easily knocked down for shipment or transportation, and which in the setting up requires neither bolts or screws nor outside tools. The invention comprehends a suitable support and a series of arms pivoted thereon and adapted to turn in vertical planes, so as to lie parallel with each other and close to the support or to be extended fan-like into horizontal position.

SIDEHILL HARVESTER.—No. 795,672. July 25, 1905. F. H. Willms, Knights Ferry, Cal. This invention relates to an apparatus for the cutting of grain and like products. It is particularly designed to maintain the thrashing and cleaning portion of the mechanism in a substantially horizontal position, both transversely and longitudinally, and independent of any variations in the grade of the land which is being passed over by the machine. It consists in the combination of devices by which the body of the machine is allowed to swing by gravitation while the wheel frame and other parts are subjected to movement caused by inequalities of the land.

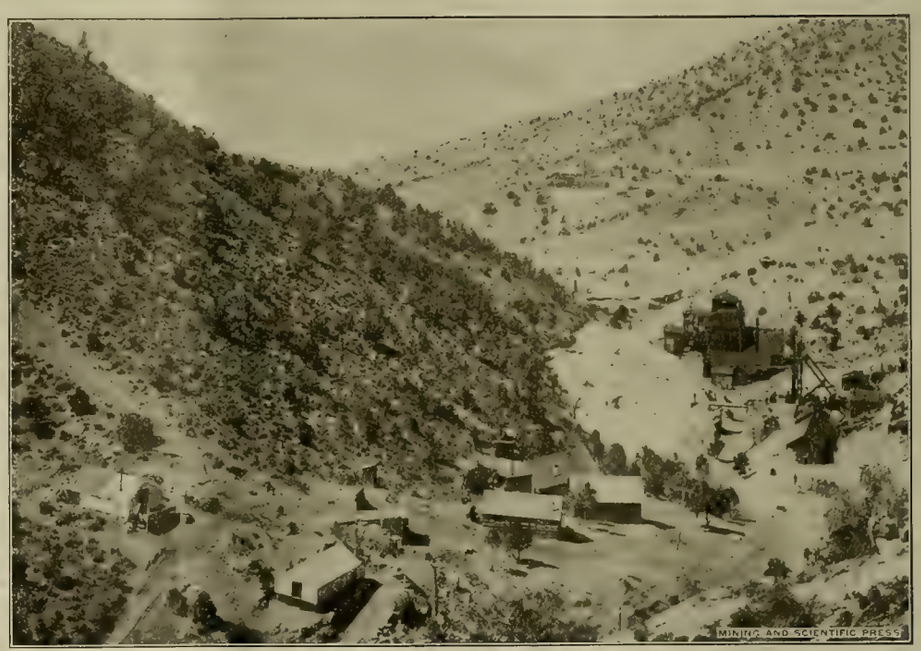
MINING AND SCIENTIFIC PRESS.

Whole No. 2351.—VOLUME XCI. Number 7. SAN FRANCISCO, CAL., SATURDAY, AUGUST 12, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

The Relation of Plant to Mine.

Notwithstanding the oft-repeated warnings of the mining press, and the spectacle of the numerous monumental blunders—to call them no worse—in mine equipment, the practice of building reduction plants entirely out of proportion to the capacity of the mine, and of installing plants in which one portion is wholly out of balance with the others, continues. A newly organized company has come into possession of several small mines in an old district of the Southwest, where the industry has been fagging for some years past, owing to a number of causes. The new company evidently intends to put some vigor into things, as it is stated the expectation is to build a 20-stamp mill and roasting and cyanide plant of fifty tons daily capacity. The ores of the district in question are remarkable for their free-milling qualities. The sulphides present in the ores are chiefly pyrite, with small amounts of chalcopyrite, blende, galena and mispickel. Free gold, visible to the eye, is of frequent occurrence. The rational process in the treatment of this ore is the crushing of the quartz in a stamp mill, concentration after amalgamation (and this, by hydraulic classification and division of the product to concentrating machines of proper design, should be readily and cheaply accomplished), and subsequent treatment of the concentrates. The method of treatment of the concentrated sulphides, in a district such as this, remote from convenient and inexpensive transportation facilities, is one requiring careful study and experiment. The chlorination process is available and it is known that a high percentage of values can be extracted by this means. The cyanide process is also a possibility here, and very probably it would work satisfactorily on these sulphides after roasting, but that a 50-ton roasting and cyanide plant would be necessary where the capacity of the 20-stamp mill is not likely to greatly exceed this amount, and where the quantity of sulphides does not exceed 2%, is not the first thing that comes to mind. It seems improbable that it is the intention to roast the entire product of the mine where the conditions are as here described. It is possible, however, that the local papers have erred in stating the company's intentions. It would be far more satisfactory to know that the latter suggestion is the case than to contemplate the result of another folly in a district previously unfortunately handicapped by inexperienced management and several installations of improper machinery.

The Cactus Mill and Trestle, Newhouse, Utah. (See Page 109.)



The Cactus Mine, Near Newhouse, Utah. (See Page 109.)

Concentration Mill of the Waltham Mining Co., Idaho Springs, Colo. (See Page 114.)

A GREAT many prospectuses descriptive of mining properties, shares in which are being offered the public, reach the editor's desk. Some of these are gems of typographical art and literary excellence, others are less so. The magnificence of the prospectus is not, however, a fair measure of the merit of the property described, any more than is the ordinary folder throughout which ignorance is stamped on every page. One of the latest pseudo-scientific effusions to be presented contains some remarkable statements. Among them is the following: "The hanging wall is porphyritic-limestone-quartz. The foot wall has not been found." One can not help speculating what frightful combination of wall rocks will be encountered when the footwall is reached. Further on this scientist informs his readers that "the ores of this region were formed undoubtedly by metasomatic alteration including pyritic mineralization and oxidation, and its attendant phenomena of transportation and enrichment. * * * The Malpi rock and volcanic formation prove beyond a doubt that the ledges go down and are true fissure veins." Prospectuses often contain exaggerated misstatements, and the intent to deceive is evident to the experienced, but this latest prospectus is evidently an effort at the honest presentation of some of the facts as observed by one of small scientific attainment—verily, "a little knowledge is a dangerous thing," particularly when it takes the form of a mining prospectus purporting to present conditions as they actually exist, to obtain money to develop a new property. The average investor is generally unable to distinguish between the genuine and spurious article.

MINING engineers and others whose business it is to examine and pass judgment upon the present value and future possibilities of a mine, while guided to a great extent by the results of their sampling, nevertheless, allow judgment to be influenced in no small degree by intuition. After all, intuitive judgment, which comes of actual experience, may not be so bad as that which blindly follows the results obtained by a mechanical operation, no matter how carefully performed.

NEARLY every mining State, from the Rocky mountain region westward to the Pacific, has abundant mineral resources, which are not only undeveloped, but which remain undiscovered. Gold, silver, copper, zinc, lead, tin, antimony, iron, mica and oil each receives abundant attention and prospectors are constantly alert to the signs of any or all of these familiar metals and minerals, but there are other minerals which have a present and growing value by reason of their scarcity and the increasing demand for them. That the rare metals and earths are not abundant it is scarcely necessary to mention, but such do occur, and it is more than probable that if prospectors generally were more familiar with these minerals their discovery would be of much more frequent occurrence. To this end it has been suggested by Prof. V. C. Alderson, president of the Colorado State School of Mines at Golden, in that State, that schools of mines and State mining bureaus be equipped with departments of research, the work of investigation and discovery being given into thoroughly competent hands. The present summer two professors of the Golden school have been in the Dolores region of Colorado exploring for vanadium and uranium minerals. Other minerals, other than the metallic, are later to receive attention. This is merely suggestive of what may be accomplished in almost any of the Western mining States through the channel of properly directed effort. Rare minerals are known in Colorado, South Dakota, Wyoming, Utah, California and throughout the West generally, and all, seemingly, that is required is that competent men be employed by the several States to search for these minerals and, discovering them, possibly lay the foundation for a number of new industries. As a matter of course, these things cannot be done through unaided individual effort, but through the aid of the States, much of value may be accomplished in this direction.

Merit of Small Importance in Speculative Investment.

Mines are not always taken up and developed on intrinsic or relative merit. Good prospects are not uncommon in some districts where mining has become an every-day business, divested of the glamour incident to days of rich strikes and the consequent excitement, but their attractiveness is gone. When mining settles down to a business basis comparable with other industrial pursuits, much of the allurement is dispelled, and the tendency to speculate is dampened. It is regarded as a sure thing, too definite in its results to make it an object to those seeking sudden fortune by hazardous investment, to "take a chance."

It is a strange but noteworthy fact that in the operation of mines on the Comstock Lode of Nevada, shareholders will uncomplainingly put up assessment after assessment, as long as a shaft is being sunk, or a long blind drift run, and there remains a speculative chance of striking a bonanza Under these repeated calls for more, and still more money, the shares will have an upward tendency in the stock market, but as soon as an ore body is developed, and a dividend paid, the "bottom drops out," and the stock falls, the speculators finding a better opportunity in gambling in the uncertainties of adjoining and possibly worthless property. This has been proven time and again on the Comstock. The investing public wants a stock that moves rapidly—either up or down—they do not seem to care much which. When a new district is discovered and rich strikes are daily reported, stock companies are quickly organized on mines in the new district, and shares are offered "at prices within the reach of all," accompanied by abundant but usually irresponsible promises of large returns. The public eagerly buys. All other districts are for the time being forgotten, or cast aside, their stocks being regarded as poor investments. One may invest in a substantial stock in a dividend-paying mine. At the end of a year the mine is still paying, but the stock is quoted at about the same price as before. There seems too little of the element of chance in these substantial stocks. In the meantime stock in the "Solomon's Temple" mine has rapidly fluctuated between 3 cents and $1.50 per share. Hundreds of thousands of dollars have been lost and made by those playing the game, and yet the "Temple" has never paid a dividend, and in all probability never will When the investing public—and particularly the army of small investors—clamor so earnestly for lively stocks it seems too bad not to accommodate them, and consequently a large number of obliging promoters and stock manipulators fix up and deal the game regularly and profitably to themselves.

Meanwhile in other old, substantial and well developed producing districts are numerous prospects lying idle for the lack of necessary capital to equip and develop them—properties which would in all probability yield a good percentage return on the investment for a long period of years, but these have no attractiveness for the small speculator, and such real opportunities remain unnoticed.

In former years mines were generally equipped and developed by individuals, or unincorporated associations, the act of incorporation often taking place some years later when the value of the mine had been proven. Then the investors visited the property personally, and often took the management themselves. Now, many investors in the stock of mining companies not only do not visit the property, but often have only a vague idea of its situation, unable to state in what county it is located, and sometimes even the State is a matter of conjecture. Not infrequently the amount invested in operations of this character by single individuals reaches many thousands of dollars. The investment has been made on the representations of a stranger who is a good talker and whose promises of rich returns are generous. Men invest in such concerns who are ultra conservative in their ordinary commercial business affairs, but the opportunity to quietly speculate without injury to their standing in the commercial world seems irresistible, and they enrich the enterprising promoter to the extent of any loose thousands that may be available. From this large merchant investor, the list runs down to clerks, small storekeepers and laboring people, of both sexes, each anxious to make much out of little. The result is too familiar to all to need comment.

Ventilation of Mines.

Considerable interest has been taken recently in the problem of mine ventilation, particularly at Butte, Mont., where many of the lower levels are hot, and where the air is laden with noxious vapors, exhalations and gases. Some of these mines are on fire—that is, the sulphide ore is slowly burning, the sulphur in the ore supplying the necessary fuel, and the little remaining oxygen in the vitiated mine atmosphere keeping it going. Fortunately, these fires exist in only a few places, and no doubt in time the ore will be entirely removed from around the burning sections, and fires will then burn themselves out for lack of material upon which to feed, when the ore may be removed. Many of the mines of Butte, like those of other large mining camps, are already connected by underground workings, or such connections may easily be made, but in numerous instances doors or bulkheads have been placed in these connections to prevent trespass. It has been suggested that mine ventilation might be vastly improved by substituting doors of iron bars for the airtight wooden ones, thus allowing fairly free passage to the air current, while defeating the cupidity of envious or unscrupulous neighbors.

Of great interest in connection with this subject of mine ventilation and sanitation is the report of the royal commission of Western Australia on the ventilation and sanitation of mines. This commission was directed to make inquiry as to the condition of ventilation and sanitation of the gold mines of Western Australia, the effects of the said conditions on the health of the persons employed in the mines, and the measures which should be taken, where necessary, to bring about an improvement thereof.

This inquiry was one of the most thorough and extensive ever officially undertaken in reference to metal mines. In the operation of coal mines the question of ventilation is a most important one, and for many years has received abundant attention; but while conditions of ventilation in metal mines in many districts—particularly in those where the mines are dry—are bad, no such far-reaching investigation had been previously undertaken. It was determined by the commission that the principal causes of ill health among underground workers were rock dust held in suspension in the air, due to rock drilling and the handling of ore in the mines, and the presence of too large an amount of carbonic acid and gases resulting from the explosion of nitro-glycerine and other explosive compounds. The greatest number of fatalities were due to the fumes from these explosives.

The findings of the commission as to the causes of foul air in the mines, and the suggestions for the improvement of existing conditions, are most interesting and important, and will be referred to at greater length hereafter.

IN some of the important coal mining districts of the eastern United States the operators are complaining of the numerous holidays demanded by the miners and men working at the coke-making plants. During the year 1905, it is stated that in the Pittsburg district of Pennsylvania there were 150 holidays, occurring through the observance of Russian, Slavonic, Italian and Hungarian holidays, and the National, State and other holidays of the United States. In addition to these, some of the men demand time to observe certain saints' days. This frequent breaking up of working crews has become a most exasperating feature of mine management.

CONCENTRATES.

WATER in a state of rest exerts pressure equally in all directions.

✻✻✻✻

OIL at 6 cents per gallon and coal at $5 per ton about balance as to cost.

✻✻✻✻

THE gold production of the United States for 1904 is stated to have been $84,551,300, an increase over that of 1903 of nearly $11,000,000.

✻✻✻✻

A STEEL HEADFRAME may "attract the lightning," but no record of the destruction of a steel frame from this cause has been published. Wooden frames are more likely to suffer from lightning than steel.

✻✻✻✻

THE question of the relative efficiency and cost of mine ventilation by fans or air compressors must be determined by existing conditions. It is very expensive to ventilate mine workings by means of a small compressor plant.

✻✻✻✻

WHETHER or not it will be profitable to strip a piece of mineral ground depends entirely upon the cost of operation and the relation of this cost to the result in working the ore body, gravel or other mineral deposits beneath.

✻✻✻✻

VERY few of the gold dredgers now at work in California are taking the gravel from the true bedrock. It is mostly obtained from a false, or higher, bedrock—a layer of volcanic tuff or mud covers the real bedrock, and also probably older gravel.

✻✻✻✻

GOLD occurs in sandstone as well as in metamorphic and eruptive rocks. In some instances the occurrence of gold is not accompanied by intrusive rocks, though usually dikes are present or in proximity to the occurrence of ores in sedimentary rocks.

✻✻✻✻

FRESH zincblende just from the mine, and which is but little if at all oxidized, has no appreciable effect on cyanide solutions, but that in the oxidized zone, or which has been for some time on the dump and subjected to oxidizing influences, decomposes cyanide solutions.

✻✻✻✻

THE capacity of a blast furnace for either lead or copper ores depends to a great extent upon the ores, but no furnace can be successfully or economically run with a capacity of less than thirty tons daily. The larger furnaces are much more economical in fuel, labor and general expense to the ton of ore handled.

✻✻✻✻

WHERE ladders are placed in a vertical shaft there should be platforms laid at least every third set, usually every 15 feet. This insures the safety of men who may be obliged to climb out long distances——a difficult and dangerous task where there are long stretches of vertical ladder unbroken by platforms or other resting places.

✻✻✻✻

THE occurrence of dark colored figures, resembling moss and trees in the fracture planes of many rocks, and commonly called "forest rock," is due to the capillary infiltration of mineral oxides into these planes. Usually, these dentritic infiltrations are iron and manganese oxides, though after oxides and salts of the metals make similar deposits.

✻✻✻✻

THE superficial parts of some of the copper mines of Butte, Mont., were first worked for placer gold by sluicing. Later, in depth, the ores were milled for gold and silver values, and still later for the copper contents of the ores. The Alice, Lexington and other veins on that lode are of a different character from most of the copper mines of Butte district.

✻✻✻✻

RAPID running increases the wear of hoisting ropes and it is, therefore, better to increase the load than the running speed. In doing this the limit of safety must be considered. A ¾-inch plow steel rope has a breaking strength of twenty-five tons. The safe allowable load is five tons. This includes the weight of skip or cage, the rope itself, and the rock placed in the skip.

✻✻✻✻

THEORETICALLY, one ounce of zinc shavings should precipitate six ounces of gold or three ounces of silver from cyanide solutions containing them, but in practice a very much larger amount of zinc is required than is indicated by the theoretical reactions taking place in the precipitation boxes. It has been shown, however, that the richer the solution in gold the less the amount of zinc required per ounce to precipitate it.

✻✻✻✻

IT is the custom in nearly all the deep mines throughout the West where a large number of men are employed for the men to take their lunches underground with them on going on shift, or to have them sent down at the proper time, the food being eaten underground. At some of the larger mines it would require an hour or more to raise the men, give them thirty minutes on the surface and send them back to the working places. This is ordinarily considered an expensive loss of time.

✻✻✻✻

MOST black sands from placers and the beaches of lakes, bays and the ocean, contain more or less magnetic iron, but all of the grains of iron ore present in such sands are not magnetic. There is often present titanic iron, hematite, and limonite, pseudomorphs after pyrite. The magnetic iron results from the degradation of basic rocks in which magnetic iron abounds, both as an original constituent and of secondary occurrence resulting from the alteration of iron bearing minerals, such as hornblende.

✻✻✻✻

THE question of the right of an apex owner of a vein to follow his vein on its dip beneath the patented land of a senior agricultural locator has never been directly determined by the Supreme Court of the United States. A case involving this question was presented to the Supreme Court several years ago in the case of the South Spring Hill G. M. Co. v. Amador-Medean G. M. Co., but the properties involved in the suit passed to the ownership of the same persons, and the case was thereupon withdrawn from the courts.

✻✻✻✻

THE water rushing through the head gates of a dam may be prevented to a great extent from cutting by the construction of an auxiliary rough dam across the stream below the gates. By allowing the water to pass through the gates under control, opening the gates slowly until the lower basin is filled, the gates may then be left wide open as long as there is a sufficient flow of water to fill them. When the low stage of water comes the gates will be closed, but with coming again of the flood season the same thing may be repeated.

✻✻✻✻

WHERE plows and scrapers can be employed on ditch work, the cost of excavation can be reduced considerably over shoveling by hand. In digging a ditch along a hillside, under ordinary conditions, a man will loosen with a pick and shovel out from 7 to 9 cubic yards of material in 10 hours. In mountainous places narrow and deep ditches are more satisfactory than broad and shallow ones. The former cost less and require generally less repairs. Surprisingly little damage is due to washing of the sides on steep grades in the mountain sections of ditches.

✻✻✻✻

IN iron smelting the blast is heated by the inflammable gases resulting from combustion of the materials in the furnace. This inflammable gas is chiefly carbon monoxide. Very little of such gas is evolved in copper or lead smelting in cupola furnaces, and consequently the blast must be heated by other means. In reverberatory practice there is always abundance of heat from the fuel used and from the burning of sulphur in the ore, and this heat can often be utilized for heating air for the blast furnaces or for steam making and for other purposes.

✻✻✻✻

ARCHÆAN and Algonkian rocks are both pre-Cambrian in age, but the two are often confounded, particularly where the area of rock exposed is comparatively small. Geologists consider those rocks only Archæan which are the oldest rocks known, with no limitation in depth, being, in fact, the original crust of the earth. It seems somewhat doubtful if such rocks actually exist exposed on the surface. In some instances, the Archæan appears to grade into the Algonkian, though the latter are supposed to be clastic rocks derived from the degradation of the older Archæan crystalline rocks.

✻✻✻✻

THERE are those who believe that the growth of certain kinds of vegetation is promoted by the presence of the oxides of various metals in the soil. Thus, there is said to be a "lead plant," the presence of which is thought to indicate the existence of lead ores in the rocks beneath the surface. Certain other plants are supposed to indicate the presence of other minerals. These are known as "indicative plants." The idea is an old one, but has been heard little of in late years. It is scarcely likely that there is anything of importance in it, or these indications would have been more closely observed and followed to a definite conclusion long ere now.

✻✻✻✻

BY metamorphism normal rocks lose their identity more or less completely. A limestone is often found changed into a crystalline marble, or if it were originally an impure limestone it might be altered into hornblende schist, in which barely a trace of the original calcium carbonate remains. A siliceous iron carbonate may be changed to an actinolite schist in which is an abundance of magnetite. Carbonaceous shales are altered to graphitic schists; dikes of basic magnesian rocks are altered into magnesian schists; sandstone becomes mica schist, or a dense hard quartzite. There are many other forms of metamorphism, of which the above are the most commonly seen.

✻✻✻✻

A STOCKHOLDER in a mining corporation cannot relocate a mining claim owned by the company in which he is a stockholder because of the failure of the company to perform the annual assessment required by law on unpatented claims. Nor can he perform the work himself and "advertise the company out" If, through neglect to attend to the assessment, the company loses the claim, the stockholders who lose thereby may sue the company for the damages sustained. Any other person not a stockholder in the company may relocate the claims for such failure to perform the annual assessment work, and there is no law which prevents such third party from giving an interest in the relocation to a stockholder who has sustained loss through negligence of his company.

IT is seldom that the best oil wells are obtained at the place where the oil seepage occurs, for the reason that at the place where the oil oozes from the rocks is the outcrop of the oil bearing stratum, though in some instances the seepage may be due to a fissure which extends down to the oil-bearing formation beneath. The former, however, is the more common occurrence. It is the wells which penetrate the oil sand some distance below its outcrop that is the most profitable. In many oil fields there are several strata containing oil separated by a greater or less amount of rock in which the oil occurs sparingly, or not at all, and in such case a bore hole sunk at the point of seepage of an upper layer of oil-bearing formation might penetrate a lower stratum and produce a profitable well.

✻✻✻✻

THE ideal condition of bedrock in a placer mine is a soft, somewhat decayed rock having many irregularities, such as is afforded by the upturned edges of mica schists and slaty rocks. When this rock is so decomposed that it may be shoveled up from 1 inch to 6 inches deep, it usually catches and holds the gold passing over it in the stream. The condition is improved if the stream crosses the strike of the formation and the grade is light. Where the grade is steep and the channel narrow, the bedrock is usually found smooth and gold only lodges in the cracks of the jointing planes of such rock. It sometimes works its way several feet downward into such cracks. To secure this gold the bedrock must be taken up. The best pay is usually on bedrock, though there are many exceptions to this.

✻✻✻✻

WHEN an engine, air compressor or other similar machine is worked beyond its capacity, it ceases to be an economical machine, as it costs more, for the work accomplished, than it would if a machine of proper size were employed. The use of a machine much too large for the work to be done is equally bad, as it is expensive to operate and the wear and tear amount to proportionately more than where the machine is suited to the work. For this reason it is inadvisable to install a large and expensive hoisting plant to sink the first 1000 feet of a deep shaft. A smaller machine of proper size is more economical in cost, operating expense and power required, and the larger engines, to be put in place later, are not worn out before they enter upon a period of activity for which they were designed.

✻✻✻✻

WHERE ore bodies outcrop along the surface of a vein it is not always good business to run a long crosscut tunnel to reach these ore bodies in depth while still undeveloped, unless development on adjoining property proves that the ore goes down. Long tunnels run for this purpose are frequently disappointing in their results, as often no ore is found. In a case such as that stated above, it would be better judgment to develop the superficial portion of the vein first, and either mill or ship the ore for the profit that may be derived from the operation, using the proceeds in the running of the tunnel. In other words, make the mine pay for its own development. It is often said that "this ore is only on the surface, with depth it will get richer." There is no rule nor experience in mining which justifies such a conclusion, though there have been instances where such a condition has been found. Enrichment of this character is of local occurrence.

✻✻✻✻

BY using 5¼-inch piston drills on the Henderson Point rock work in Portsmouth harbor, New Hampshire, holes were drilled in hard trap to depths varying from 50 to 79 feet. The drills were operated in series, seven machines being bolted to a frame of heavy timbers, set in the bottom of a pit behind a coffer dam. Two hundred and three lifting holes were thus drilled, which were 6 inches diameter at the start, decreasing to about 2 inches diameter at the bottom of the deepest hole. Thirty-eight tons of dynamite were used in exploding the entire series of holes bored, there also being numerous down holes. The blast dislodged 35,000 cubic yards of solid trap rock. The sticks of powder used were made to order and ranged from 2½ to 4 inches diameter and 24 to 30 inches in length. About one-half the powder was 60% nitro glycerine, the remainder being 75%, or somewhat stronger than the ordinary No. 1 powder. Nine hundred exploders were required for the work.

✻✻✻✻

THE nickel and cobalt consumption of the United States and Canada is practically controlled by the International Nickel Co., which owns and operates extensive mines in Canada and also in New Caledonia. The metallurgical works at Orford, N. J., also handle nickel and cobalt ores, also American Metal Co., 52 Broadway, New York. In view of the above, it is difficult to state what percentage of nickel and cobalt in pyrrhotite or other ores would pay. The lowest percentage of copper in sulphide ores that will pay is that percentage which will yield a return in excess of the cost of production. This is variable, depending upon conditions and circumstances which must be fully known and understood. Ordinarily a copper ore to be profitable under favorable conditions, and where shipped to a custom smelter, should carry at least $10 worth of copper. This should pay for the cost of mining, transportation and reduction, together with the usual discounts. Where the same person and company owns both mine and smelter and the ore is self-fluxing, the value of the ore may under favorable conditions pay when containing only $4.

Problem in the Storage of Granular and Lump Material.*

Written by W. E. Hunter and J. S. Meyers.

It is a well-known fact that certain kinds of material, dropped from a fixed point of discharge, will—depending upon the material—assume definite angles of repose which are notably uniform in slope over the surface of the pile, rendering the computation of a close approximation to the contents of the pile or weight of the material an easy matter.

This angle of repose P (Fig. 1) is for anthracite coal 27°, for bituminous coal 40°, for dry sand 33°, etc. Often, however, the piles—whether in the open or under cover—are confined at the base by vertical retaining walls, thereby destroying the symmetry of the natural conical shape, and the amount of this confinement may vary from the single vertical wall placed at one side to complete enclosure of the base by four such retaining walls forming a rectangle. To compute the contents of the pile of material under these circumstances becomes one of some difficulty if necessary to resort to an elementary calculation, consequently it is customary to use approximation methods for the purpose, and while it may be conceded that the approximation methods are sufficiently accurate, the diagrams herewith exhibited have the merit of not only greater accuracy, but also of affording greater expedition in practice. The probability of error is likewise minimized.

In Fig. 1, which is the representation of a conical pile enclosed at the base by four retaining walls, with the apex O midway between the walls C' C and B' B, it is seen that the solid within one quadrant is made up of a parallelopiped having the base O L C D and altitude I H, and also that portion of the quarter cone within the walls having its apex at O in plan and O' in elevation and altitude J O'. It is, therefore, necessary to obtain the contents of the two portions of the quarter cone cut off by the walls C' C and C B, having the bases C L F and D C E and altitudes H G and J K, so that these volumes may be subtracted from the contents of the quarter cone.

The mathematical treatment in a condensed form is as follows, referring to Fig. 2:

Let a = altitude of cone;
r = radius of base of cone:
z = distance from axis of cone to cutting plane; given in figure as Z_1. Subscript dropped for simplicity;
V = volume of entire cone;
v = volume of portion cut off by plane.

We have

$$z^2 + y^2 = R^2, \text{ and } R : x :: r : a;$$

$$\text{therefore } y = \sqrt{\frac{r^2x^2}{a^2} - z^2} = \frac{r}{a}\sqrt{x^2 - \frac{a^2 z^2}{r^2}}$$

$$\text{and } v = \frac{2r}{a}\int_{\frac{a\,z}{r}}^{a}\int_{z}^{r}\left(x^2 - \frac{a^2 z^2}{r^2}\right)^{\frac{1}{2}} dx\, dz =$$

$$\int_z^r\left[a\,(r^2 - z^2)^{\frac{1}{2}} - \frac{a\,z^2}{r}\log_e\frac{r + \sqrt{r^2 - z^2}}{z}\right]dz =$$

$$\frac{a\,r^2\,\pi}{4} - \frac{2\,a\,z\sqrt{r^2 - z^2}}{3} - \frac{a\,r^2}{2}\text{ arc sin }\frac{z}{r} + \frac{a\,z^3}{3\,r}\log_e\frac{r + \sqrt{r^2 - z^2}}{z} - \frac{a\,r^2}{6}\text{ arc cos }\frac{z}{r}.$$

The characteristics of each of these terms of v are given in diagram A, both positive and negative terms, for economy of space, being placed above the zero line. The curve designated $\frac{v}{V}$ gives the proportion of the volume severed from the cone to the volume of the entire cone. This ratio is constant for the corresponding ratio $\frac{z}{r}$, irrespective of the dimensions a and r, consequently it is only necessary to obtain the volume of the whole cone and multiply it by this ratio as given in the table or from the curve, and the volume of the portion severed is arrived at. For instance, if it is desired to obtain the contents of that portion of a cone remaining from which has been removed a part exterior to a cutting plane situated midway between the axis and the outer extremity of the base, we first ascertain that the ratio $\frac{z}{r} = .50$, and a reference to the diagram shows that the ratio of the part cut off is, to the entire cone, .110.

Diagram A and the table accompanying it were not worked out with more accuracy than may be obtained by means of the ordinary slide rule, as the writers, desiring a diagram more suitable to rectangular bins, were agreeably surprised to find that a combination of two cutting planes, as shown in diagram B, very much simplified the formula for purposes of calculation. This formula was obtained by means of the proper substitutions, displacing z by its value as a function of the angle ¢ in the following:

$$\frac{v}{2} - v_1 - v_2 = \frac{a\,r^2}{3}$$

$$\left[2\sin 2\phi - \cos^3\phi\log_e\tan\frac{90° + \phi}{2} - \sin^3\phi\log_e\cot\frac{\phi}{2}\right]$$

Making a and r each equal to unity in the above formula gives the formula for the unit semi-cone. This unit value C_1 was used in plotting diagram B, and is shown thereon. The solution was made for the semi-cone, as it is not always practicable to have the apex at the geometrical center of the bin. The formula and curve may be as readily used in the case where the apex is not placed centrally in either direction by taking one-half the reading of the curve, which then applies to a quarter cone. Formula C_1 may also be transformed to give tons or bushels, as

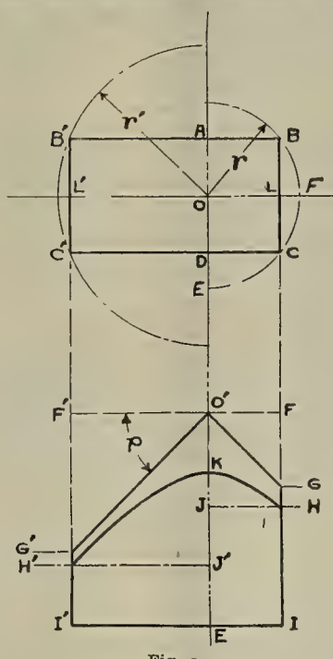

Fig. 1.

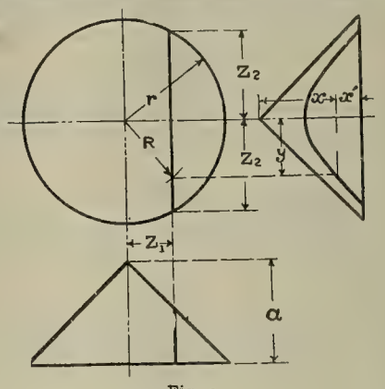

Fig. 2.

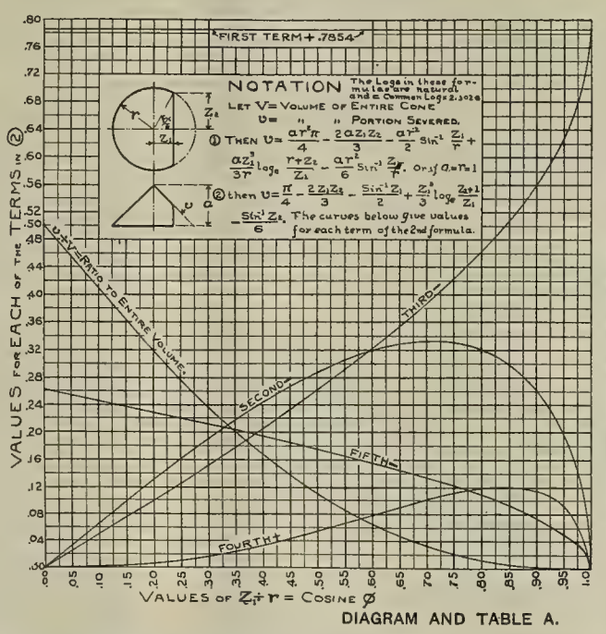

DIAGRAM AND TABLE A.

CO-ORDINATE DISTANCES

For each of the terms in the expression for the volume of the portion of a cone severed by passing a cutting plane parallel to the axis, from Formula 2. By inserting all the coefficients in formula 2 the 3rd and 5th terms summate. Let a = r = 1 as before, let ϕ = angle in degrees; formula 2 then becomes $v = .7854 - \frac{\sin 2\phi}{3} - .00582(135 - \phi) + 2.3026\frac{\cos^3\phi}{3}\log\frac{1+\sin\phi}{\cos\phi}$. ③ Logs in ② are common logs.

CONSTANTS FOR VOLUME OF SEMI-CONE ABOVE THE PLANE x x
HAVING RECTANGULAR BASE PRODUCED BY CUTTING PLANES PARALLEL TO THE AXIS.
VALUES OF C_1
VOLUME OF SEMI-CONE REMAINING = $a r^2 C_1$.
VALUES OF $\frac{Z_1}{r}$ = TANGENT ϕ.
AXIS OF CONE
THE VALUES OF C_1 WERE CALCULATED FROM THE FOLLOWING FORMULA, USING 7 PLACE LOGS.
$C_1 = \frac{1}{3}\left[2\sin 2\phi - \cos^3\phi\log_e\tan\frac{90°+\phi}{2} - \sin^3\phi\log_e\cot\frac{\phi}{2}\right]$.
THE LOGARITHMS IN THE ABOVE FORMULA ARE THE NATURAL LOGS. TO USE COMMON LOGS MULTIPLY THEM BY 2.3026 OR ADD .3622157 TO THE LOG OF THE LOG IF PERFORMING THE OPERATIONS BY LOGARITHMS.

Diagram B.

*Engineering News, July 27, 1905.

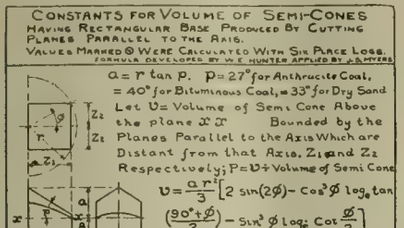
desired, by multiplying it by the proper constants for the material forming the cone. The values of C_1 given to five decimal places were calculated, intermediate values being readily interpolated from the curve.

Table B gives values of C_1 corresponding to values of $\frac{Z_2}{Z_1}$ = .36 to 1.00, advancing by .02 interpolated from the curve. The column headed P gives the proportion of the volume remaining to the volume of the semi-cone. The column headed C_2 gives the coefficient by which to multiply r_3 to obtain volume when the material stored is anthracite coal, the angle of repose of which is 27°. This table covers the range for practical purposes, as it would not be economical to construct bins under ordinary circumstances with a width less than about 0.5 to 0.6 of the length. In use the reading of diagram A should be multiplied by

CONSTANTS FOR VOLUME OF SEMI-CONES

HAVING RECTANGULAR BASE PRODUCED BY CUTTING PLANES PARALLEL TO THE AXIS.

VALUES MARKED ® WERE CALCULATED WITH SIX PLACE LOGS. FORMULA DEVELOPED BY W. E. HUNTER APPLIED BY A. MYERS



α = r tan p. P = 27° for Anthracite Coal,
= 40° for Bituminous Coal, = 33° for Dry Sand
Let V = Volume of Semi Cone Above the plane X X Bounded by the Planes Parallel to the Axis Which are Distant from that Axis, Z1 and Z2 Respectively; P = V ÷ Volume of Semi Cone
$V = \frac{\alpha r^3}{3}\left[2\sin(2\phi) - \cos^2\phi \log_e \tan\left(\frac{90°+\phi}{2}\right) - \sin^2\phi \log_e \cot\frac{\phi}{2}\right]$
or V = C1 α r³; For P = 27°, V = C2 r³ C2 = .509525 C1

VOLUME OF SEMI-CONE (WHEN α r² = 1) IS $\frac{2}{3}$ = .6666

Table B.

the contents of the complete cone and the product subtracted from the entire contents. The reading of diagram B should be multiplied by the product of the altitude and the square of the radius of the base; the result will be the contents of the semi-cone within the bin, and this result divided by two will give the contents of the quarter cone within the bin.

EXAMPLE.—A bin for anthracite coal is 230 by 160 feet and the apex of the cone is at the center of the building and 80 feet 8 inches from the floor. Required the capacity of the bin:

$z_1 = 115$, $z_2 = 80$, $r = \sqrt{z_1^2} + \sqrt{z_2^2}$, and $a = r \tan 27°$.

$(115)^2 = 13,225$
$(80)^2 = 6,400$

$r^2 = 19,625$
log r^2 ..... 4.2928079
log r 2.1464040
log tan 27° 9.7071659

$\frac{z_1}{z^2} \frac{80}{115} = .695$, hence C1

from curve = 4332 and
log C_1 ..... 9.6366884

Log V_2 ..... 5.7830680 and V_2 = 606,830 cu. ft.
and 2 V_2 = 1,213,660 cu. ft.
log r 2.1464040
log tan 27° 9.7071659

log a ..... 1.8535699 a = 71.379

80.667
71 379

9.288

log 9.288 9184479
log 160 ..... 2.2041200
log 230 ..... 2.3617278

5.4842975

therefore, contents of parallelopiped is equal to ..... 305,000 cu. ft.
contents of conical pile ..... 1,213,660 cu ft.

contents of the bin ..... 1,518,660 cu. ft.

This amount multiplied by $\frac{52}{2000}$ = 39,485 tons, the required capacity in tons of 2000 pounds, taking the weight as 52 pounds per cubic foot.

Available Supply of Platinum.

The Electrical Review says that the Croselmire & Ackor Co., 42 Walnut street, Newark, N. J., platinum, gold and silver refiners, announce that the situation in Russia is becoming so serious, and the supply of available ore so scarce, that it is possible, and not at all improbable, that before the first of the year it will be almost impossible to purchase platinum in quantities of any account. Prices are advancing almost daily, and in the next month or so the price of platinum will be very high. Platinum to-day is worth from $21 to $21.50 per troy ounce, according to the supply.

A Mine Superintendent's Difficulties in Nicaragua.

Written for the MINING AND SCIENTIFIC PRESS.

An impending sense of coming trouble forced itself on my just awakened susceptibilities one morning early in the first month of the current year.

The writer was the superintendent of a mine in Nicaragua, and that day the "Jefe Politico," or sheriff, after having attended the festivities of proclaiming a neighboring pueblo, was to pay our mine a visit.

In a moment of weakness I had consented to entertain this official with his numerous retinue; to provide them with a light "almuerzo," and show them underground. Well, we live and learn.

In the first instance, such a proposition meant, of course, the complete disorganization of the working staff, and no work being done that day.

The enthusiastic mine boss had fixed the main entry to the mine with native and home flags; and, in addition, had embowered it with a young forest of saplings, so that our ordinary business-like adit now had the appearance of being fixed for a school treat, or some such popular festivity.

On the flagpole at the office floated the blue and white emblem of native patriotism; although, I am bound to confess, I had no evidence of anyone even noticing this, our offered tribute.

The first contingent arrived during the morning, but these seemed to comprise most of the unofficial hangers on. The big man himself was reported "hors de combat" from the very strenuous undertaking of attempting an all-night "baile" copiously supported with certain well-known stimulants.

After a weary wait of most of the day, at about 4 P. M. the Jefe Politico and staff, accompanied by a heterogeneous crowd of followers, and that indispensable adjunct, the brass band, without which no government official would so demean his dignity as to preside at any function, no matter how insignificant, arrived.

As time was pressing I at once made inquiries as to whether the colonel and staff desired to go underground. On the reply being in the negative I was immensely relieved, as the very evident incapable state of all hands would make such a visit highly exciting, if not positively dangerous.

The modest luncheon that had been prepared early in the day was now called for, and with suitable apologies served. The cook had been somewhat generous in the quantities of mustard with which he had sought to impart a suitable "gusto" to the otherwise insipid sandwiches, and to the most callous palate they were, indeed, a trifle "piquante."

The first contingent, whose palate was more or less normal, after a trial had positively refused to suffer further; and so our apprehensions were great as to the favor with which our further efforts in this regard would be received. Apparently the pungent relish acted as an antidote to the jaded palate, and in many cases seemed to pass unnoticed—although to the normal innocent tears would start unbidden to the eyes. And so the lunch proved an unqualified success.

Almost at 5 o'clock, when the men, who had been in readiness all day, were preparing to leave, the big man felt sufficiently recovered to remember the object of his visit and expressed a wish to undertake the journey underground.

Numerous objections were offered, and I even brought to bear some manifest fabrications, alleging the mine to be full of powder smoke owing to the nearness of "shooting time," which would be highly dangerous to their excellencies. However, nothing would avail; in fact, they rather thought they might relish the smoke, and supremely despised any intimated danger.

So, as there was no alternative, without giving grievous offense—which in those autocratic countries would be extremely impolitic—the order was given to go below.

Although the main entry was but a stone's throw distant, it was not compatible with the honor of "caballeros" to walk, and so the whole party mounted and went clattering down the hill. The colonel, in fact, thinking possibly he was leading some desperate charge, cantered across the bridge and was half way up the opposite hill before he could be halted and ignominiously brought back.

The party were manifestly in no condition to go underground on foot, and so the accommodation provided was there. Timber trucks fitted with platforms and seats came into service very handily.

The mine boss, who had himself grown a trifle hilarious by this time, undertook a little pyrotechnic display on his own account, and also to demonstrate the efficiency of the particular brand of powder used, scattered with a free hand amidst the horses and riders whole sticks of powder with a short lighted fuse. The detonations were soon something fierce; but happily, beyond a little trouble with the horses, there was no damage done. Altogether the prospects looked a little unpropitious, with such an unruly crowd, to attempt the entry of the mine. However, in we went, the three automobiles with their mozos in the van, and the stragglers following as best they could. The mine was profusely lit with candles placed in the levels, crosscuts and rises, so that there was no lack of light. All went well until we reached the main shaft, when the mine boss would insist expatiating on the glories of the undertaking, which so interested the Jefe Politico that nothing would suffice but that he must get out and see these wonders for himself. So impressed was he that in honor of the project he called for his band and insisted on having a tune.

Great was his disgust when he found that the instruments had been left outside. After some maneuvering I managed to get the party aboard again and gave orders for full speed ahead to the end of the drift, some half a mile farther.

My sole anxiety now was to get the party through and out again without loss of limb or life. On arriving at the "breast," with little more adventure than a dump or two around the curves all hands alighted.

In two crosscuts near the breast six rounds had been drilled in each and loaded. After sundry efforts on the part of the boss to practically demonstrate how the holes were drilled, in which I had to discontinue his efforts as he was operating perilously near the charged holes, the Jefe declared his wish to see the holes fired. I can picture the scene very vividly now—the Jefe at the entrance to the crosscut within a foot or two of the spitting fuse, yelling at the top of his voice "Fire! Fire!" and waving his arms over his head, apparently in blissful ignorance that there were a half dozen shots in close proximity, and spitting for all they were worth. Seeing the state of affairs, I yelled to the other men not to spit their shots and devoted my efforts in getting the enthusiastic party into some place of safety. We had barely retreated to the switch when off went the shots, one after another; and, as a consequence, the entire party was left in darkness, as all the candles were blown out by the rush of air in the drift. The martial sound of the shots evidently awoke the latent patriotism and warlike sentiments, and "Vivas" galore were yelled by the crowd for the president, evidently with much gusto.

Now the proposition was to get the crowd out again.

The members of the band took a fancy to be trammed out in the mine cars; accordingly, they were hustled aboard into three cars and trammed out at a good lively gait, as the grade of the track is in places considerable, and the mozos did not spare their victims.

It was a matter of considerable congratulation that none of the cars were derailed and the occupants seriously injured; for as a matter of fact they must have come out of that drift seemingly like a shot out of a gun. As a matter of fact the entire party emerged in perfect safety—the members of the band a little sadder, but possibly wiser men.

By this time it was quite dark. After the inevitable delay the Jefe, followed by the cavalcade, headed for the office. On arriving there he evidently felt it encumbent on himself to deliver a speech, as it appears customary in Spanish countries on every possible occasion to speechify. Earlier in the afternoon we were given the benefit of some very lofty flights of oratory, which, boiled down, I expect, meant very little, if anything.

However, it seems inherent in the Spanish nature to express sentiment in the most ornate manner, whether called for or not; and so in this case the happy period of departure was thereby dragged out to such a length, assisted by a few supplementary drinks, that I was beginning to think if we ever should see the end of it—or whether some unfortunate occurrence might not cause some little six-shooter practice, as all the guests were, as customary, armed; when eventually the whole party, headed by the jubilant Jefe, drew off into the darkness and the night and left one individual, at least, devoutly thankful for their safe departure and vowing never again to volunteer or consent to entertain any Government official on any pretext whatever, in any part of the Spanish Americas.

Portable Trams in Mine Stopes on the Rand.

In stopes of small inclination the use of some form of conveyor has become the general practice, says the Government engineer of the Transvaal Department of Mines.

A form of conveyor has been found successful at the Lancaster G. M. Co. It is the invention of J. Faull, the manager, and takes the form of a double line of tramways on which a pair of skips are operated by gravity under the control of a brake. The two skips are joined by a wire rope which passes round the brake drum at the head of the stope. The full skip pulls up the empty one. The skips are self-dumping at the lower bin, this being effected by a door at the lower end of each skip which opens automatically when the skip lands on a buffer at the ore bin.

The claim to novelty consists in the portable nature of the apparatus, sections of parallel rails being fastened at gauge to light sleepers, in suitable lengths, which can be connected and disconnected readily,

and which also can be folded over on to one another for the purpose of removal or storage. Besides the facility of handling which the hinging affords for folding purposes, it also allows the rail track to accommodate itself to the uneven contour of a stope floor, and in practice it has been found that this flexible track is admirably adapted for the purpose for which it is designed.

It has been found desirable to construct the track in sections of different lengths, the shorter sections of 3 feet being found to follow sharp undulations of the floor more closely than the 9-foot sections, which are suitable for stretches that are less uneven.

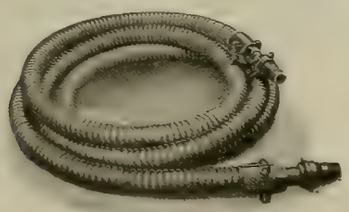
In the narrow stope between the second and third levels of the Botha mine about 70 feet of parallel double tracks are laid, made of 3-foot sections of 18-inch gauge. On these tracks are two skips of 9 cubic feet capacity each.

In another and wider stope between the sixth and seventh levels similar tram lines are being worked, only in this case the tracks are of 2-foot gauge, and the sections in lengths of 9 and 3 feet, while the skips are of 16 cubic feet capacity. The number of boys engaged in serving these two skips, which convey a ton of ore from the front face to the ore chute, a distance of some 70 to 80 feet, every two or three minutes, is eight, viz., six at the loading station, one operating the brake, and one clearing the discharge. The installation of this folding track allows ten shovelers to be dispensed with, besides more rapidly performing the work.

Regarding the portability of the tram lines, 4 feet of single track was folded up and transported in four minutes and relaid in six minutes. These times need to be doubled to obtain the rate for rigging and unrigging the double track. It has been recently definitely proposed to use belt conveyors, in 600-foot lengths, to handle the ore on the main incline (complementary to the main vertical shafts) of the deep level mines of the eastern section of the Witwatersrand. The inclination of the reef is not expected to be greater than 20°, while it may be as flat as 8°, and it is felt that some method of continuous mechanical transport will prove more economical than ordinary methods of skip winding.

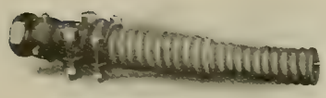
Flexible Steel-Armored Hose.

Mining superintendents and others will be interested to know of a new product in the line of armored hose, the construction of which prevents any collapse, as the armor binds the rubber lining so tightly that even after the rubber part becomes useless the loss of steam or air is so small that the machine may be continued in operation until it is convenient to replace the damaged hose. If from any cause a section of the hose is cut out, the remaining two pieces can



Coil of Flexible Steel-Armored Hose.

Splicing Clamp.



Re-enforcing Bushing.

be coupled together without interfering with its efficiency. The armor incases the hose completely so that no part of the rubber lining is exposed to external injury. The efficiency of the hose is increased, as it is practically impossible for the hose to kink or flatten, thus maintaining a uniform internal diameter which is essential to perfect circulation of steam or air. It is obvious that a hose of this character is not continually in the repair shops.

The steel-armored hose consists of a high-grade rubber hose closely covered with an exterior metal armor composed of interlocking strips of galvanized steel wound spirally in such a manner as to give extreme flexibility. Special couplings and fittings have been designed, and can be supplied for mechanically connecting the armored steam or air hose in the most reliable manner to various makes of drills.

This new product is manufactured by the Sprague Electric Co., 527 West Thirty-fourth street, New York City, who will be pleased to send a descriptive bulletin, No. 50,537, upon request.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

NUMBER III.

Written by T. H. OXNAM.

This clayey portion, which we term "slimes," is allowed to dry as much as practicable, and is then treated by agitation in a separate plant, as will be described farther on in this paper.

Figs. 2 and 3 show the arrangement of the cyanide leaching plant in plan and in elevation.

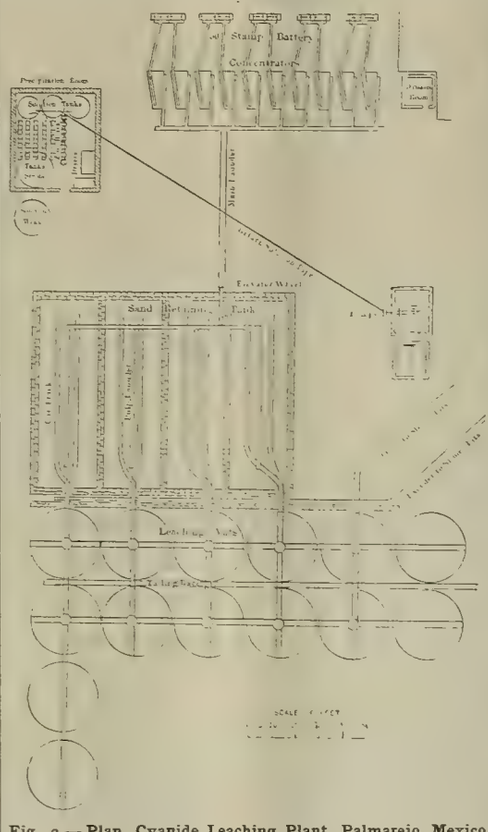


Fig 2.—Plan, Cyanide Leaching Plant, Palmarejo, Mexico.

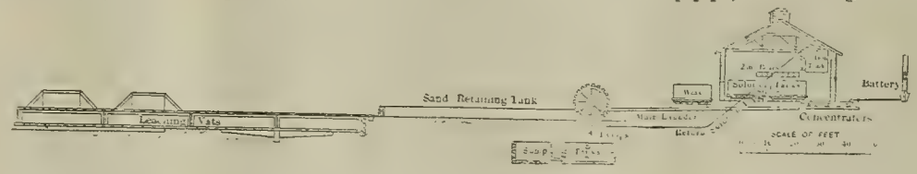

Fig. 3.—Cyanide Leaching Plant—Elevation.

CYANIDE TREATMENT OF SANDS.—The sands retained in the compartments of the large masonry sand retaining tank, after being allowed to drain as long as possible—usually from 36 to 48 hours—are trammed by half-ton cars to the cyanide leaching vats, twelve in number and each 30 feet in diameter and 4.5 feet deep. The filter bottom, which reduces the available depth to 4 feet 2 inches, consists of a wooden, lattice framework covered by a layer of cocoa matting, over which is stretched a filter cloth of 8-ounce duck. Two heavier grades of duck have been tried as filter cloths, but it was found that they tended to reduce the rate of leaching and gave less satisfactory service than the 8-ounce cloth. Ten of the leaching vats are constructed of No. 9 sheet steel; the other two were built here on the premises and are made of 3-inch native pine. Two additional vats of the same dimensions and capacity, made of 3-inch redwood throughout, are now in course of erection.

The sands, as charged into the leaching vats, carry from 14% to 16% of moisture. Each vat is charged with the equivalent of 100 tons of dry sands. While being trammed to the leaching vats, slaked lime is added to each car, usually in the proportion of from 4 to 5 pounds of lime per ton.

The vats are filled and discharged by contract for $19 a vat, which is equivalent to 19 cents per ton.

Two strengths of stock solutions are employed, the weak solutions averaging between 0.25% and 0.30% of KCN, and the strong solution averaging from 0.75% to 0.80% of KCN. The working strength of the solutions is always taken as that indicated by titration with silver nitrate in presence of a few drops of 10% solution of potassium iodide, as an indicator, 10 c.c. of the cyanide solution being taken for titration. For the sake of convenience, we still express the strength of our working solutions in terms of potassium cyanide, although for over a year we have been employing sodium cyanide exclusively. Titration with silver nitrate shows that the sodium cyanide being used is, on an average, equivalent to about 125% of potassium cyanide. Our experience at this place with sodium cyanide leads us to believe that it is fully as efficient as potassium cyanide for the dissolution of the values contained in the ore. It also appears that, since commencing the exclusive use of sodium cyanide, our solutions become rather less fouled than was previously the case. Freighting expenses are always a considerable item with us and by the adoption of sodium cyanide, equivalent, as above stated, to 125% of potassium cyanide, a saving of 20% of the freighting expenses on this article has been effected. Granted, as our experience seems to confirm, that sodium cyanide is equally as efficient as potassium cyanide, it would seem probable that it will gradually displace the latter, which, until recently, has been almost universally employed. Besides the direct saving in transportation expenses, the sodium cyanide appears to possess other advantages. From a metallurgical standpoint, other things being equal, it would seem preferable to use a salt as nearly pure as is to be obtained. Absolutely pure sodium cyanide being equivalent to about 132% of potassium cyanide, a product testing from 125% to 130% of potassium cyanide is manifestly nearly pure. It by no means follows, however, that the ordinary commercial cyanide, rated as 98% to 99% pure, and which by the usual silver nitrate titration will stand up to this strength, contains but 1% to 2% of impurities. That this commercial cyanide frequently carries a varying percentage of sodium cyanide is a well-known fact, and it of course naturally follows, on account of the relatively greater proportion of the CN radical contained in this salt as compared to potassium cyanide, that the greater this percentage of sodium cyanide contained in the ordinary 98% to 99% of potassium cyanide, the greater will be the percentage of impurities.

In view of these conflicting results, it is to be hoped that the managers of other plants, where sodium cyanide has been tried on a large scale, will follow Mr. Oxnam's example and publish the details of their experiences. From a chemical standpoint there seems to be no reason why a molecule of NaCN in dilute solution should act differently to a molecule of KCN, nor why the gold double cyanide of the one should be more or less stable than that of the other. Possibly the alkaline carbonate, present as an impurity in varying percentages, may have had some influence in the case of certain ores. Fuller information on the subject is certainly desirable.

As soon as a vat is charged, from 20 to 25 tons of weak solution, carrying as just stated from 0.25% to 0.30% of KCN, is introduced from the bottom by means of a 2-inch drop pipe, terminating in a Tunderneath the filter. This solution is introduced slowly in order to avoid channeling of the charge, and it usually makes its appearance on top of the sands about six or seven hours after being turned on. When the solution stands 2 or 3 inches above the top of the charge it is turned off and the material is allowed to soak for six hours, during which time the material will usually have settled from 3 to 4 inches. The weak solution discharge valve at the bottom of the vat is now opened and leaching is commenced. During the next two, or sometimes three, days, weak solution is added from the top as rapidly as permitted by the leaching rate of the charge until a total of from 100 to 130 tons has been applied. From 60 to 70 tons of strong solution, averaging between 0.75% and 0.80% of KCN, is now run through the charge at a somewhat slower rate, the usual time consumed for this operation being about forty-eight hours. Weak solution is now run through the charge as rapidly as possible, until within about twenty-four hours before the time it is to be discharged, when wash water to the amount of from 15 to 20 tons is added in lots of about 5 tons each. The residue is now ready for sluicing, which is accomplished by two men in about six hours, each using a 2-inch hose, equipped with a 0.5-inch nozzle and operating under a head of 72 feet. After finishing the sluicing out the canvas filter is usually swept clean with a broom, it being found that if this is not done the filter cloth frequently tends to become clogged with very fine slimes and the rate of filtration is lowered. Each vat is equipped with two 10-inch by 10-inch square bottom discharge doors.

The quantity of wash water used is regulated principally by the balance of the solutions on hand. Although a separate zinc box is provided for waste solutions, it is very seldom used excepting during the rainy season, as very rarely during other times of the year is any solution run to waste. Only two of the leaching vats are under cover, and during the rainy season it frequently becomes necessary to run a certain percentage of the solution to waste, as during

*Trans. Amer. Inst. Min. Engrs.

each heavy rain the exposed vats will collect a very appreciable quantity of water.

It has so far been my experience that as thorough oxygenation as possible of the material being treated is a very desirable feature in the cyanidation of most gold ores, and, in the case of the Palmarejo ores, it appears to be absolutely essential in order to obtain the best results. Due to the fact that the major portion of the value of the material being treated is in the silver content, the actual weight of fine metal to be acted upon is much greater than is ordinarily the case with gold ores.

In order to permit of as much air being supplied to the sands as possible, the solution during the treatment is frequently allowed to drain down several inches beneath the surface of the charge, air being thus allowed to penetrate the material to this depth. It is our custom to assay each charge every 24 hours, after the first 5 days of treatment. Before each sampling, the solution is also usually allowed to drain down several inches below the surface of the sands, thus allowing additional opportunity for the entrance of air into the upper layer of the charge.

Under the most favorable conditions, however, the air drawn into the top layer of the charge can have but little effect on the lower half. It is doubtless due, at least largely, to this difference in aeration to which the upper and lower portions of the charge are subjected, that practically without exception, when ready for discharging, the lower half of the charge will run from 1 to 2 ounces of silver higher than the upper half. Frequently this difference is even more marked, and occasionally a difference of as much as three or four ounces will be obtained between the upper foot and the bottom foot of the charge.

To overcome this difficulty to a certain extent, after many experiments, the practice was adopted some time ago of transferring as many charges as possible from one vat to another during the treatment. To transfer a vat means the loss of practically 24 hours of its available leaching time, as it is necessary to drain the charge for about 12 hours before commencing to transfer it. Also it is necessary that one of the adjoining vats be empty at the proper time to receive the transferred charge. By careful manipulation, at present, about one-third of the total number of charges treated are transferred. When the two additional vats, which are now in course of erection, are completed, a greater number of charges can be transferred and the additional capacity afforded will also permit of a longer treatment to offset the time lost in transferral. The transferring is done by contract for $16 a vat, which is equal to 16 cents per ton. While being transferred, the material is of course given a thorough exposure to the air, any existing lumps are broken up by the shoveling, and, roughly speaking, the bottom layer of the original charge becomes the top layer of the transferred charge. The period during the treatment at which the transfer is made naturally depends upon the time at which an adjoining vat can be empty and ready to receive the transferred sands, but operations are usually so timed that the transfer takes place while the strong solution is in contact with the material. During the transfer, about 100 pounds of slaked lime are evenly distributed near the bottom of the vat receiving the transferred charge.

The charge is sampled just before and just after transferral, the latter sample being nearly always about 1 ounce higher in silver than the former, a result which is doubtless due to the fact that in taking a sampling the almost unavoidable tendency is to obtain a larger percentage of the top half of the charge than of the lower half; and, as above mentioned, the lower half of the original charge, after the transferral, becomes practically the upper half of the transferred charge.

The first solution added after the transfer is introduced slowly from the bottom, after which the regular routine treatment is continued. The value of the effluent solution from a charge is invariably found to increase immediately after the charge has been transferred, such increase being usually from 2 to 3 ounces of silver per ton of solution.

In general, all heads and tailings samples of the sands treated are taken with a 1.5-inch auger at from 12 to 16 different points of the charge.

Table I gives a part quantitative analyses of two samples taken some time ago of the mill product after concentration and ready for cyaniding. The composition of the sands now being treated will doubtless vary but little from that of these samples:

TABLE I.—PART QUANTITATIVE ANALYSES OF SANDS.

Composition	Sample No. 1.	Sample No. 2.
	Per Cent.	Per Cent.
Insoluble (chiefly SiO_2)	88.40	81.90
Iron	1.20	1.05
Sulphur	Trace	0.17
Manganese	2.37	1.87
Lime	2.88	6.00
Magnesia	0.61	1.38

NOTE.—Qualitative analyses of the ore before concentration show the presence of small quantities of antimony, arsenic and bismuth, and occasionally traces of zinc and copper are found.

Tables II and III give a complete record and analysis of the results obtained on a charge which was transferred during treatment. Although dealing with but a single charge, these results represent those regularly obtained in ordinary operations.

TABLE II.—DETAILED RECORD OF SANDS TREATMENT.

Charge No. 744. Net tonnage, 100. Moisture, 15.5%. Lime added, 0.25%. Assay value per ton was $2.08 of gold and 15.40 ounces of silver.

The effluent solution from the leaching vats is carried to the sump tanks by means of two separate lines, one for the weak, the other for the strong solution. These tanks are of masonry and are three in number. Two of them, having a combined capacity of 65 tons, are connected together and serve as a weak solution sump; the other, having a capacity of 25 tons, is used for the strong solution. All solution draining from the leaching vats is passed through the zinc boxes before being returned to the vats.

The proper tonnage of strong solution is maintained by frequently determining the strength of the effluent solution from the leaching vats, and when this strength reaches about 0.35% of KCN the solution is turned into the strong solution sump. As a working guide for maintaining the proper alkalinity of stock solutions, they are titrated every day with the addition of about 5 c.c. of strong lime water, 10 c.c. of cyanide solution being used in all titrations. If the addition of the lime water causes a difference of more than 0.5 pound in the indicated strength of the solution, the quantity of lime added to the sands charged into the leaching vats is increased.

From the sumps the solution is elevated by means of a 3-inch centrifugal pump, running 900 revolutions per minute, a vertical distance of 29 feet, through a horizontal distance of about 150 feet, to three storage tanks at the head of the zinc boxes. These tanks are each 10 feet in diameter, 8 feet deep and have a capacity of nineteen tons. Two of these tanks are used for the weak and one for the strong solution. The solution from the vats now passes through the zinc boxes, from which it is led to three storage solution tanks beneath the boxes. These storage tanks are made of No. 9 sheet steel, each one being 15 feet in diameter, 6 feet deep and of a capacity of thirty-three tons. Two of them are used as strong solution storage tanks, the other as a weak solution storage tank. The strong solution is brought up to the required strength by adding the necessary quantity of cyanide to the last compartment of the strong solution zinc box, which is reserved for this purpose. No cyanide is ever added directly to the weak solution.

(TO BE CONTINUED.)

Vulcanized Fiber for Friction Clutches.

The construction of a dredger that can stand up to the unusually severe work required in dredging river gravels for gold has been a task that has been but lately accomplished. The first dredgers built were continually breaking down, and for a time it was feared that economical running would be prohibited by the high cost of repairs. Continual experimenting has proved that manganese or other hard steel is necessary for the bucket plates. The bearings have at last been practically perfected and the manufacturer now has time to give attention to minor details.

One of the latter has been to find a suitable material for the surface of the friction gearing used in some makes, for transmitting the power. Rolling cylinders are frequently used to transmit force, and constitute what is known as friction gearing. In such cases the axes are arranged so that they can be pressed together with considerable force, and, in order to prevent slipping, the surfaces of contact are made of slightly yielding material, such as wood, leather, rubber or paper, which, by their yielding, transform the line of contact into a surface of contact, and also compensate for any slight irregularities in the rolling surfaces.

Considerable difficulty has been experienced in finding a material that would safely hold the heavy load of lowering dredger buckets from 40 to 60 feet below water level. The experience of a large San Francisco firm in this matter has finally led them to adopt either Eastern maple or a vulcanized fiber, giving preference to the latter, as the maple will burn if subjected to great frictional force.

This vulcanized fiber is produced by treating specially prepared vegetable fiber with chemicals, whereby the outside of each separate fiber becomes glutinous, and while in this condition the whole mass is consolidated and becomes homogeneous. After the chemicals have been extracted the mass is rolled, pressed and cured, so as to give the vulcanized fiber of commerce.

It is claimed that it is insoluble in all ordinary solvents, and that it is not injured by contact with alcohol, ether, ammonia, turpentine, naphtha, benzine, petroleum, or any of the animal or vegetable oils. It absorbs water, but is not injured thereby. The hard, vulcanized fiber is prepared in sheets 44x66 inches and from 0.005 to 2 inches thick. Sheets from $\frac{1}{8}$ to $\frac{3}{4}$ inch are usually used by the dredgers. It can be worked in a lathe, drilled, riveted, sawed and punched. It is not brittle nor easily broken, and possesses great strength, elasticity and durability. The Electric Railway & Manufacturers' Supply Co., 68 First street, San Francisco, Cal., carries a large stock of this material.

THE new abrasive alundum is the result of the fusion of the mineral bauxite in the electric furnace. Bauxite is a hydrated oxide of alumina, and is in some respects similar to corundum. The latter contains no water and less aluminum than bauxite. It is a new material sold in competition with carborundum, which is also made in the electric furnace from the fusion of silica and carbon.

Placer Mining in Alaska.

In consideration of the importance of the placer mining industry in Alaska, an exhaustive investigation of the mines and mining methods in vogue in the far North was undertaken by the United States Geological Survey, the results of which have been published in Bulletin No. 263 by C. W. Purington, and from which the following has been abstracted:

OPEN-CUT MINING.—Under this heading will be discussed the various methods of mining by which gravel is taken out of open cuts—either simple pick-and-shovel methods or methods involving the use of mechanical contrivances. The simplest of the open-cut methods dominated throughout the province up to within a few years, to the practical exclusion of all others except winter drifting. To-day probably 60% of the placer mining operations in Alaska are confined to open-cut methods, and this investigation has proved that, when combined with proper mechanical devices, these form often the most economical mode of exploitation.

Open-cut methods can be conveniently grouped under various headings, but the underlying principle of excavating and transporting the material to the washing apparatus, either by hand labor or by some mechanical means, remains the same.

ROCKER AND LONG TOM.—The simplest method of work which the miner adopts after he has passed the stage of panning is that of shoveling from the bank and washing the gravel in a rocker. The form of rocker employed in the Klondike, where its use has been nearly discontinued in mining, is shown in Fig. 1. Two men are necessary to use the rocker properly, while only 3 to 5 cubic yards of gravel can be washed in ten hours. At no place was the long tom seen in use in the North, although it was formerly employed to some extent in washing the Nome beach placers.

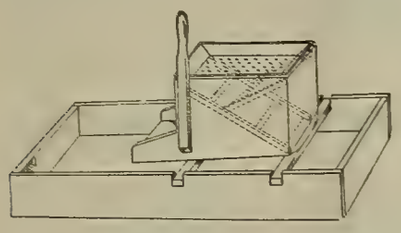

Fig. 1.—Klondike Rocker.

SHOVELING INTO SLUICE BOXES. — Conditions throughout many of the Northern placer districts favor this method of placer mining, for in many localities the pay streaks are thin, ranging from 2 to 4 feet in thickness, rarely exceeding 5 feet. It is often applicable where conditions of transportation prohibit the installation of more elaborate plants.

When the total depth to the bottom of the pay streak does not exceed 12 feet, the overlying barren material can generally be "ground sluiced" off, even where the grade does not exceed 1%, at an expense varying from 7 to 20 cents per cubic yard. The frozen muck which composes this overburden is from 50% to 75% water, and the solid residue of silt or fine clay is easily carried away at any time of slight rise in the stream.

On Anvil creek five strings of boxes with 120 shovelers give a twenty-four-hour capacity of 1080 cubic yards.

The handling of water is important. Even when the gravel has been solidly frozen previous to stripping and sun thawing, there are generally from 15 to 25 miner's inches of seepage water, which works into the pit floor. This must be disposed of either by draining or by pumping. If sufficient water (50 miner's inches) is available, a "China pump" can be rigged up. This device is not economical in its use of water, for the water is generally of more value for other purposes in Alaska mining.

DAMS.—As in all other forms of creek mining, great care must be taken to keep the creek water out of the working pits by means of dams. Dams constructed of sod walls lined with sacks have been found cheaper in the Klondike than those built of sod and brush. Pile driving is not advisable in the North, but in case timber is abundant cribbing is desirable. In a dam built across Discovery Fork of American creek the ends of the logs were set in frozen ground on both sides and the muck was allowed to refreeze around them. The dam, 40 feet long, consists of 12-inch timbers, from 9 to 18 feet long, laid up in two rows 5 feet apart, earth and rock filled, and braced with cross timbers. The dam, self-dumping gate and accessory flumes were built by two men, and are said to have cost, in labor and time, only $300.

A self-dumping gate was introduced on Discovery Fork during June, 1904, in "booming" the overburden from the area of pay ground which it was desired to uncover. Swinging on its horizontal axle, set two-thirds the distance from the top to the bottom of the gate, it releases the water when the reservoir becomes full and regains its closed position when the reservoir is nearly empty. During a period of three weeks a block of overburden consisting of muck and barren gravel, 5 feet thick by 25 feet wide by 900 feet in length, had been removed by the booming process before the shoveling operations commenced, the total cost, including the construction of the dam and gate, not exceeding 7 cents per cubic yard.

The process of booming by means of automatic water gates was formerly generally in use in California. As a rule it is inapplicable to mining or stripping in Alaska, because the stream grades are gentle and because the debris carried down by the torrential stream will damage property situated farther down the creek.

On Hunker creek, in the Klondike, a dam of moss, brush and gravel, 90 feet long and 18 feet high, built for the purpose of keeping the water from an open cut, cost $500. Dams in Seward Peninsula are successfully built of sod, the material which overlies the frozen muck to the depth of 2 feet. Sacks of sand are also successfully used.

DRAINS.—Below the proposed pit a backwater dam, generally 4 feet in height, is built across the creek, and the end of the sluice is extended beyond this dam a few feet. Assuming that the ground is to be worked upstream, the method of laying off the drain, commonly called the "bedrock drain," is as follows: In 12-foot ground take a level and sight downstream from the prospect pit to a point where 12 feet vertical distance above the water in the stream is obtained. The sight should be taken at a point 2 feet above the surface of the ground, to allow for the height of the backwater dam. The point where the drain is to be started is the distance downstream obtained by the sight plus 12 feet, allowed as a safety factor. On a 2% grade this would necessitate a drain 612 feet long. The drain is dug and left open until after the first cut is made. Its dimensions are generally 2 by 2 feet and it is lagged inside with poles horizontally, these being held by posts with 4-foot centers, into which shoulders are cut for caps. After the first cut the drain must be covered by logs and moss laid on top of the caps. For small operations a box drain made of sawed 1-inch lumber, the inside dimensions being 12 by 10 inches, is used. There should be a standpipe bored with auger holes in the drain at the lower end of every cut. The drain should have a very slight grade, as low as 1½ inches to 100 feet being used. At first the drain will handle only seepage water, but if one cut of 100 feet in length after another is successively worked upstream, sluice water may have to be run through it to prevent backing up. Some operators recommend keeping the main drain large and giving it the bedrock grade, while a smaller drain, 8 by 8 inches, is kept parallel to it on a less grade. This will handle the seepage water and will gain depth upstream, thus allowing for inequalities in the bedrock, which are very frequent.

On Mastodon creek, in Birch Creek district, a bedrock drain, 500 feet long, dug 4 feet wide, lagged inside with 4-foot cord wood, making it 2 feet in the clear, and covered with poles and moss, was dug through cemented and frozen gravel and bedrock, and cost $7000, its construction consuming all of one season. In the Fairbanks district an open drain, not lagged, 3 feet deep and 3 feet 6 inches wide, took the labor of two men six weeks, costing nearly $900.

In excavating for drains the ground should be cut in terraces, so that when it commences to thaw it will not run and clog the canal. Pumping seepage water from the pit is to be condemned in general as

Placer Miner's Cabin in Alaska.

Rocking on the Beach at Nome, Alaska.

Open Pit Mining in Alaska.

strongly as pumping water for sluicing. In Bonanza creek, Klondike, an operation involving the handling of several thousand yards was said to be more expensive by 40 cents per cubic yard when pumping of the seepage was done than when the water was handled by drain. The pumping of seepage water by any form of pump may be estimated to add at least 25 cents per cubic yard to the expenses of handling the gravel. The use of overshot wheels operating China pumps is cheap where water is plenty. A small one was using 20 inches of water to lift about one-third this amount a height of 10 feet. Such a pump in the Klondike, with 5-foot wheel, costs $100 to build.

Cost of Shoveling.—The cost of a plant, including that of constructing a seepage water drain, sod dams and a string of ten sluice boxes, with a ditch to lead the water to the sluice, varies from $500 to $2000, according to the conditions. The expense of handling gravel by this method is from $1.25 to $2.50 per cubic yard, reaching $5 to $7 in remote districts.

The duty of a man shoveling is variously estimated in different districts of the North. This form of mining having been nearly discontinued in the Klondike region, very little information concerning it was obtainable. In one case, where a platform was used, two men shoveling in two stages a total of 9 feet lift, 2 feet of pay were shoveled into the boxes at the rate of 3½ cubic yards per ten-hour man.

In Birch Creek district the duty of a man shoveling, from an average of twelve operations, is 5 cubic yards in ten hours, the depth of pay averaging 4.41 feet, and the lift never exceeding 6 feet.

In American creek, where the boulders were large and men had to stop work to get them out of the way, the duty was 2¾ cubic yards. On Discovery Fork of this creek the duty was 4 cubic yards, the depth being 5 feet.

In the Nome region 5.76 cubic yards duty is probably very near the average on a bank from 5 to 7 feet in height. In the case of the large operations of the Pioneer Mining Co., on Anvil creek, the work has been so systematized that on the 3-foot bank handled the duty is 9 cubic yards per ten-hour man.

The method of working shallow placers by shoveling into boxes has much to commend it, especially when the water is drained from the cut, either with or without a covered drain. In Alaskan gravels exceeding $3 in gold tenor to the cubic yard of material handled by shoveling, frequently from one-half to two-thirds of the gold lies in the crevices of the upper 18 inches or 2 feet of the bedrock. Men directly shoveling this material can thoroughly clean the bedrock by the shoveling-in method. On the other hand, if horse scrapers, steam scrapers or steam shovels are used the bedrock is frequently not cleaned, and a gang of men must go over the ground a second time to pick up the auriferous material which has been left. This point is of the first importance. No operator should contemplate the installation of mechanical excavators for working gravel without taking full account of it.

In considering methods of mining by water or mechanical power, the cleaning of bedrock by men may be permissible from an economic standpoint in exceptional instances, as, for example, where a thick overburden is cheaply removed by hydraulicking and a very thin rich pay streak remains. When, however, a mechanical method of removing overburden and low-grade gravels costs from 50 cents to $1 a yard, and the whole area has to be gone over again by men to wheel the rich pay to the sluice, the gravel must be extraordinarily rich to pay a profit. The lowest cost of handling gravel by the method of shoveling in was found to be $1 per cubic yard on one of the creeks of Seward Peninsula, while the cost may reach $5 on some of the isolated interior creeks of Alaska. From 10 cents to $1 per square yard of area worked must be generally added to the shoveling cost to cover the cost of stripping muck or overburden. Ground which exceeds 12 feet in depth of combined stripping and pay will rarely pay if handled by the method of shoveling into the sluice.

(To be continued.)

Gold in the Philippines.

Gold is found in the Philippine Islands in a number of localities. As recently as May 14, 1904, there were reports of a rich gold strike—128 ounces in a short time under primitive methods—by an American prospector in the provinces of the Camarines. The capital is Nueva Caceres, a city of 12,000 inhabitants, about 207 miles from Manila. Silver, iron, copper and lead are also known to exist in the same mountains. Specimens of quartz from another point—Paracale—assay 38 ounces of gold to the ton. In Benguet (the highlands of the Philippines), where the summer Government station is to be erected, the gravels of the river Agno carry gold. In another district, years ago, natives produced 150 ounces of gold per month, using only cocoanut shells as dishes. Copper also is reported from many localities. Copper ore was smelted by the natives before Magellan discovered the Philippines. Assays show over 16% of copper in the surface ores, and the ore bodies are of good size and form a valuable undeveloped resource.

The Cactus Mine, Beaver County, Utah.*

Written for the Mining and Scientific Press

On the eastern edge of Wah Wah valley, in the San Francisco range of mountains, in Beaver county, Utah, and 230 miles in a southwesterly direction from Salt Lake City, is located the new mining camp of Newhouse. This camp is reached via the San Pedro, Los Angeles & Salt Lake railroad, Newhouse being the terminus of a branch of this road from Milford. The property is better known as the Cactus mine, which has been worked in a small way for several years. Since the present management has taken control a large amount of development work has been done and many improvements made. The tunnel is in over 6000 feet and they have drifted on the second ore body. A crosscut has been run 135 feet from wall to wall, and approximately 200 feet in length, all in ore. A shaft 614 feet deep from the surface to the tunnel level has been sunk and levels made each 100 feet. The ore from the upper levels is dropped through the shaft to the tunnel level and from there brought out by means of electric motor, there being twenty-one cars handled at a trip. Each car holds approximately 3½ tons of ore. The ore is then put through crushers, situated close to the mouth of the tunnel, and from this point loaded into railroad cars and sent to the mill for treatment. The company has built a branch road from the mill to the mine, something over a mile in length. The engravings on the front page and accompanying show the mine and interior and exterior views of the mill.

The Table Floor of the Cactus Mill, Newhouse, Utah.

Three 10x20 Blake crushers at the mouth of the tunnel are used in crushing the ore, and the bins have a storage capacity at the mine of 600 tons. At the mill the ore is brought up a 4% incline to the top of the mill, where it is dumped into bins. These bins have a capacity of 1000 tons. The ore bins are made of steel. The cars which transport the ore from the mine to the mill are hauled directly over the bins and dumped. The mill is built in two sections, which are similar in every respect.

The ore is drawn off from the bins onto belt conveyors by means of the plunger feeders, and from the conveyors delivered to the elevators. There are two elevators in each section of the mill. The belt conveyors deliver the material to the dry elevator, which takes it to the top of the mill. The elevator is 70 feet high and the cups are 6x12 inches. The material from this elevator goes to a 14-millimeter mesh trommel and the oversize to 15x36-inch rolls, where it is crushed to about 14-millimeter size and returned to elevator. The undersize from the 14-millimeter goes to a double trommel consisting of a 7 and 3½-millimeter screen. The oversize from the 7-millimeter goes to the No. 1 jigs; the oversize from the 3½-millimeter to the No. 2 jigs. The product from the Nos. 1 and 2 jigs is taken out through a side discharge. All tailings and hutch products are returned to the wet elevator—16-inch belt and 6x16-inch cups. This elevator delivers the material to the 3½-millimeter trommel, and the oversize from this trommel is returned to another set of 15x36-inch rolls for recrushing, and from jigs to wet elevator, and again to a 3½-millimeter screen until all material will pass through a 3½-millimeter. The undersize from this 3½-millimeter and the other trommel mentioned above is delivered to a 10-mesh No. 20 wire trommel. The oversize from this trommel goes to the No. 3 jigs; the undersize to a 16-mesh No. 24 wire trommel and the oversize from this trommel to the No. 4 jigs. The undersize goes to a system of Calumet water sizers, which are arranged in series. The first compartment of the sizer delivers the coarse material that will pass through a 16-mesh screen to a set of jigs running 325 strokes per minute. The next compartment delivers to a set of four Wilfley tables, the next compartment to another set of four Wilfleys, and the next compartment to two tables. The overflow from these sizers goes into a system of settling tanks. The settlings from these tanks are treated by four tables and the overflow from these settling tanks passes to sump tanks in the bottom of the mill where the slimes system proper begins. The water that flows across the heads of all the tables is also returned to the slimes system in the same manner. From these sump tanks the slimes are pumped to a set of fifteen settling tanks in the upper part of the mill. These tanks are 8x8 feet and the bottoms are in the form of an inverted cone. The purpose of these tanks is to give the slimes a chance to settle and thicken, when they are drawn off through the bottom of the tanks and delivered to a set of slime tables. All the water in the slimes settling tanks is collected in one tank and used to supply the tanks with water. On the Nos. 3, 4 and 5 jigs the tailings are discharged and sent out of the mill. The product through the first and second jigs is returned through the elevator for retreating. The middlings from the tables are continually returned to the head of the same table for retreatment. The product from all the jigs and tables are delivered through a system of shaking launders into push cars, which are elevated and dumped into the concentrates bin. The railroad cars are loaded from these bins ready for shipment. The overflow from the shaking launders is also dumped back to the slime system. At present they are handling about 600 tons per day through the mill. The water for the mill and town comes from Wah Wah springs, about 10 miles to the west of the camp, and is carried across the desert or valley in 12 and 14-inch pipe.

Gold ore has been mined and milled in California for less than 50 cents per ton.

King Solomon Mine, Frisco, Summit County, Colo. (See Page 114.)

The Hancock Jig at Penn Wyoming Co.'s Mill.

Written for the MINING AND SCIENTIFIC PRESS by R. B. LAMB.

The new Australian jig, more generally known as the Hancock jig, installed at the mill of the Penn Wyoming Copper Co. at Encampment, Wyoming, has proved a decided success. The jig is handling feed from three different trommels, one of which is 8-mesh, one 4-mesh and one 3-mesh. The ore is crushed to pass through a $\frac{5}{8}$-inch opening. The feed varies from $\frac{1}{4}$ inch to $\frac{5}{8}$ inch. The jig is handling 380 tons of this product daily.

The jig screens are, from the head downward, 8-mesh, 4-mesh, $\frac{1}{2}$ inch punched, $\frac{5}{8}$ inch punched and $\frac{3}{4}$ inch punched respectively. The rolls are fed direct from the jig.

The three products made are concentrates, middlings and tailings. The middlings are returned to the jig to feed the bed.

A notable feature of the machine is its simplicity, and the perfect control the operator has over a feed, varying within very wide limits.

The special merits of this jig are high capacity, simplicity, light screen wear; it will treat material of varying sizes within certain limits; requires little labor to operate; makes clean concentrate, and is cleanly. It requires a constant speed and regularity of feed. It requires about the same quantity of water as other jigs per ton of ore treated.

The points to be guarded against are: (1) That all moving parts be kept entirely free from lost motion. (2) Large pieces of rock must not be allowed to enter the jig, as the bed becomes immediately disturbed. (3) The speed must not vary. (4) The moving parts must be strong and free from spring. (5) The discharge must be regular.

The machine briefly described consists of a box made of 4-inch lumber, properly braced with angles and rods, as shown in the accompanying engraving. This box is approximately 25 feet long by 4 feet 2 inches wide by 5 feet 9 inches high, and forms the hutch of the jig. It is supported by cast iron legs, in order to raise the body of the jig sufficiently for the operating mechanism. This makes the total height of the jig nearly 10 feet, which is one of its objections. However, as it is customary to put the foundation of the jig underneath the operating floor of a mill, this brings the bottom of the hutch box about at a level with the operating floor.

In this hutch box, and submerged in the water, works the screen frame, or sieve of the jig. The sieve is 20 feet long by 2 feet 8 inches wide, and is divided into a series of pockets extending across the screen. These pockets are intended to maintain and hold a "ragging," or bed, through which the concentrates are drawn into the hutch. This screen or sieve is carried on two cast iron cross bars fastened to the screen. These cross bars are supported by four upright arms, two on each side. The arms or rods are connected at the bottom to rocking arm shafts, which are connected to levers, the ends engaging a three-way cam on the main drive shaft of the jig. The main drive shaft revolves at 60 revolutions per minute and the result is a reciprocatory movement imparted to the sieve, which can best be described as an upward and forward movement and downward and backward movement. The upward and forward movement is produced by the rocking arms; the downward movement of the drive by gravity, and the "bump," or backward movement, by the radial bar, which is connected to the end of one cross arm. The up and down motion is about $\frac{3}{8}$ inch; the backward motion, or "bump," is only sufficient to advance the feed properly along the screen. Both the amount of the up-and-down motion and the "bump" are controlled by proper adjustment, so that this movement can be regulated to suit different kinds of ores. The number of reciprocations of the screen is 180 per minute. Some of the special and particular features of this machine are:

1. A large production, due to the fact that the feed is carried along the screen by what is practically a reciprocating motion, and not by a current of water, another reason being the size of the machine and sieve.
2. It handles an unsized feed.
3. The jig will handle 100 tons per day as well as 500 to 600 tons.

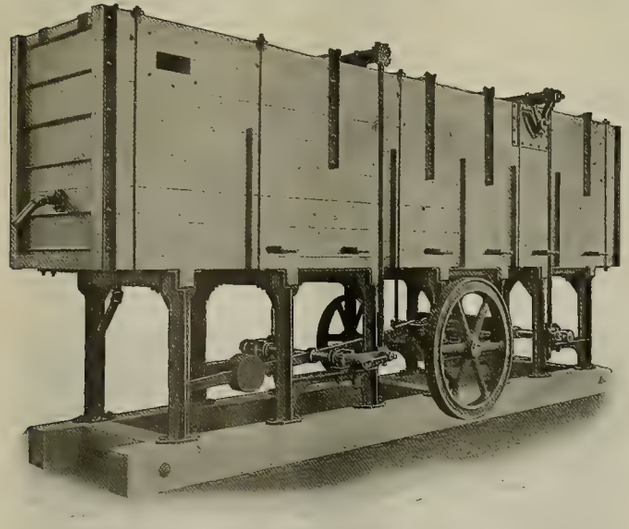
This suits the machine for a small concentrating plant, say 100 tons in twenty-four hours, as well as a large one. The Hancock jig simplifies the arrangement of launders and transmission of power.

All concentrates are made in the hutch, although it can be arranged to take off a clean concentrate from the top of the screen, if this is necessary.

In operation the fine material in the feed is taken down through the screen into the hutch at once. The finest mesh screen that the jig uses is over the first hutch compartment. The coarser part of the feed forms a ragging, or bed, for this fine concentrate. The next hutch compartment receives the medium-sized concentrates, and the third hutch compartment the coarse concentrates. In the last part of the jig, commencing where the coarse concentrates come down, the screen consists of plates punched $\frac{1}{8}$ inch larger than the largest size material the jig is handling. In this section of the jig, an artificial ragging, such as round iron punchings of proper size, is used as a bed.

In the last section of the jig, the action of hydraulic classification carries along the fine sands, while the coarse concentrates are being taken down into the hutch, an important feature of the jig. The last two hutches are usually used for middlings, all the free mineral contents of a feed being stratified and taken down into the hutch in the first three compartments. If all the middlings can be taken down in the fourth hutch, the fifth hutch is usually used for a tailings discharge. The hutch compartments can be changed as to their dimensions in order to suit different propositions by moving the cleats which hold the hutch divisions.

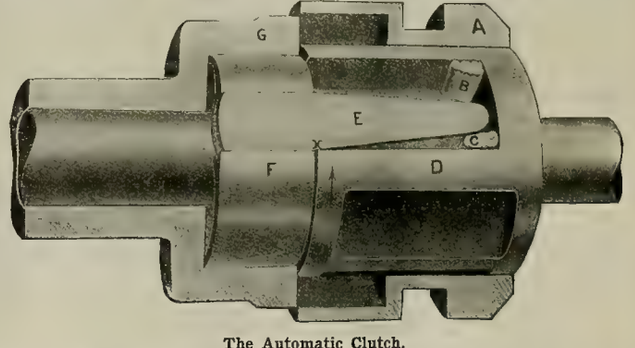
It would appear from the experience at this place that the jig would not be very successful on feed below 10 or 12 mesh, though elsewhere I am told it handles fine material with as satisfactory results as those obtained on coarse here. The jig requires a bed holder, which is made of 4-inch pieces set 4 inches apart for the entire length of the screen. These pieces must be renewed for about every 10,000 tons of ore treated. Otherwise when they become too much worn they get springy, which imparts a motion to the screen and the bed cannot be held. If the jig is solidly constructed its operation gives no trouble whatever.



The Hancock Jig.

Automatic Clutch.

Herewith is illustrated an automatic self-adjusting clutch. A is the operating sleeve which carries the pins B and C, shown in section, which fit between the faces of the cavity in the keyed member D. Loosely placed between the pins B and C is a lever E, which extends between the ends of the expansion ring F, which is surrounded by the cup or loose member G. If the keyed member D be rotating in the direction indicated by the arrow, the ring is freely revolved by the lever E, which is driven at point x, as pin C is free of the lever; and pin B operates on the lever only when the member D is revolving in the opposite direction. When the clutch is engaged the sleeve A is moved to the left, and pin C gradually relieves the bearing point x on lever, and the member D drives the ring by the lever through the pin C. This causes the lever E to expand the ring F within the cup G, with such pressure that the friction caused exceeds the force on the lever, so that "the greater the load the tighter the grip." This clutch is manufactured and furnished by the American Automatic Clutch Co., Akron, Ohio.



The Automatic Clutch.

Notes on Hydraulic Mining.*

NUMBER II.—CONCLUDED.

Written by R. L. GRIDER.

RIFFLES.—There are many different kinds of riffles in use—poles, rails, wooden blocks and angle steel riffles. The iron riffle saves gold better than the wooden and requires little or no washing, but is generally more expensive. Where sluices are not less than 200 feet in length and timber is cheap, blocks of wood are preferred. For economy in wear and increased gold saving area, place the heart side of the block up stream. Near the head of the sluices (first 120 feet) space the blocks 1 to 3 inches apart and decrease the width of space toward the dump. Never drive wedges between the sides of the flume and the blocks, because the swelling of the blocks will rip or split off the side boards from the bottom of the box, rendering it unfit for use. This is a common mistake made by miners. The blocks are prevented from floating by using a side lining of 2x6-inch or 2x8-inch scantlings which are spiked to the side of the flume. After having washed gravel four or five days, charge the sluices with mercury by pouring it into the flume from side to side in a zigzag manner up or down the flume once or twice a day. Do not strain the mercury into the flume through drilling or buckskin, as some recommend; this flours the mercury, rendering it buoyant and loss occurs. One to four pounds of mercury constitutes a charge per 50 feet of flume and alternate 50-foot sections are charged daily.

In order to obtain unamalgamated specimens, do not charge the first two or three boxes and never put mercury in the race. If the flumes are long or large and the gold fine, one to ten tanks of mercury are used per run.

DUMPS.—All dumps over 60 or 70 feet in height give little or no trouble, but lower dumps require much attention and a great amount of water to aid in spreading the materials. Spreading dumps is also facilitated by means of branch or Y sluices. When the dump at the end of one branch is full, the water is turned by means of a swinging hinged gate into another branch and a sluice box is added to the former. Consequently no time of actual mining is lost by this method.

THE CLEANUP.—The bedrock is cleaned with the pipe into the race and the race into the flume. Muddy water aids in cleaning the gold from the bedrock, and if the rock is too rough and full of seams, hand cleaning may be necessary. When the race is clean, turn the water out of the sluices, rip off and wash the slats (lining), take out the riffles or blocks, which should be thoroughly washed and laid on the side of the flume, loosen the materials adhering to the bottom of the flume with shovels or hoes, and turn on water enough (about 2 inches deep in the sluices) to wash the material down the flume. The mercury and amalgam drag along behind, and are scooped up with an iron scoop. A small auxiliary sluice leading from the side of the main sluice facilitates in cleaning up, and should be used unless there is an undercurrent or grizzly connected with the flume. The undercurrent or grizzly, however, is not economical unless the flume is short and there is plenty of water. Long flumes are always economical gold-saving contrivances. In some cases where the sluices are too short, where the grades are too high, where the sluices are poorly constructed, or where the ground contains much clayey material, the loss of gold and mercury is quite great, probably 10% to 40%. The loss of mercury depends upon the velocity of the current, the length of the sluices, the length of the run, the temperature of the water, and the character of the material, as well as the method of charging the flume. From 90% to 98% of the gold should be saved, and if the gold is coarse or heavy there is no reason why 98% to 100% should not be saved. Pipe clay and leaky flumes are the greatest sources of loss.

HYDRAULIC ELEVATING.—The action of the hydraulic elevator is like that of a steam injector. There are three kinds of these machines in general use—the Hendy, the Evans and Campbell elevators.

Place the elevator in the lowest part of the mine and deep enough in the bedrock, so that feed sluices

*Abstract of Colorado School of Mines Bulletin.

may be extended up to the workings. An hydraulic water lifter, an auxiliary to a gravel elevator, should be permanently installed by the side of the gravel elevator to keep the pit free from water when it becomes necessary to stop the elevator to make repairs, change nozzles, relieve it of obstructions, or clean up. A better method, however, is to install a double elevator, so that in case one needs repair the other can be used, and in case the volume of the water varies its capacity can be regulated to the quantity of water at command. An abundant supply of air to the upcast is necessary for good work with the hydraulic elevator, since the materials will pack and not enter the upcast if air is not admitted. Furthermore, the air, after passing the throat, is immediately compressed, so that it aids the water in raising the material. The upcast—i. e., the pipe leading up to the outer flume—discharges the material against a striking plate or grate, which deflects the material downward into the outer sluice. This plate gives much trouble when the boulders are hard, heavy and large, since they are impinged with great force against the plate or grate. A grate of steel bars, bent to the proper form, gives a better resistance than a plate, wears longer, and is more easily repaired. These bars are securely anchored in the top of the first box of the outer flume. This box must be covered, clamped, rigidly constructed, and weighted with boulders. Usually no grade is given to the first box of the outer flume, since the materials are discharged into it by the elevator with such force that they are carried from 10 to 40 feet down the flume. The grade for the second box should be 1 to 2 inches, that of the third 2 to 4 inches, and so on until the maximum grade for the outer flume is reached. The construction and equipment of the outer flume is identical with that used in hydraulic mining operations. The elevator should be fed regularly, and it works better when fed by a bedrock feed flume. To attain good results, the maximum amount of gravel should be elevated with a minimum amount of water, since the cost of lifting water is as much as or more than that of lifting gravel. The proportion of the distribution of water to the elevator is about two-thirds of the estimated volume, the remainder being used by the giants for piping.

Grizzlies are arranged in the bedrock feed flumes to prevent cumbersome boulders or other large material from entering the elevator and choking it. As soon as an opening is enlarged, cut the bedrock feed sluices upward from the elevator pit toward the bank for economy in the transportation of the material to the elevator, in the feeding of the elevator, and in the catchment of the gold. Much experience is necessary for successful mining with the hydraulic elevator. It not only requires engineering skill to install a successful elevating plant, but it requires technical engineering ingenuity to keep the machinery working to the best advantage.

Hydraulic mining, as a whole, requires scientific methods of work before success can be hoped for. No matter how favorable all the conditions may be, good business management will still be an indispensable requisite to success in such an undertaking. The ground contains large amounts of precious metal, but it is scattered through a vast amount of barren material. To collect it, immense quantities of dirt must be very quickly and very skillfully worked. Any carelessness in the technical part will result in large losses, but want of business management will result in larger. Economical management is, therefore, an essential requisite to success.

Galvanized Iron.

The first method of coating iron with zinc was electrolytic, says the American Manufacturer, that is, a solution of zinc such as zinc sulphate or chloride was employed through which an electric current was passed, the work to be zinced forming one pole and a sheet of zinc the other. The wet or electrolytic process was soon abandoned in favor of the hot or molten process, as there were no efficient low tension dynamos which are essential for the economical working of such a process, and the coating applied was found to be unreliable. The hot molten process consists of dipping the article into a molten bath of zinc (at a temperature of about 800° F.) covered with a suitable flux, such as sal ammoniac. From time to time various improvements, relating to the mechanical details, have been introduced into the working of the hot process, having for their object the reduction of the amount of zinc consumed for a given area of iron, but, unfortunately, such a reduction results in a corresponding decrease in the durability of the galvanized articles. Sheets are passed through squeezing rolls as they leave the bath; wire through asbestos rubbers or sand; nails and similar articles are placed, when the zinc is still molten, in centrifugal machines to remove as much zinc as possible. Another improvement of some moment has been the introduction of close annealing to reduce the amount of oxide formed, and the subsequent removal in acid. Sand blasting—that is, projecting sand at a few pounds pressure on the article to be freed from scale—has been substituted for the wet acid process for some classes of work.

THE PROSPECTOR.

The mineral specimens from Burnt Ranch, Cal., are: No. 1 granular quartz, with an abundance of pyrite—iron sulphide. No. 2 is massive quartz, with a little pyrite and some talc on one side; the brown and yellow color is due to iron oxide. No. 3 is an eruptive rock (diorite-aphanite) and is evidently the wall rock of a vein; the black color is due to the multitude of microscopic grains of magnetite. No. 4 is quartz containing pyrite. Nos. 1, 2 and 4 probably are gold bearing.

The rock sample from Truckee, Cal., consisting of a small sack of broken pieces, is a good grade of copper ore. Most of it is chalcopyrite in quartz gangue. The mineral is altering to bornite, which occurs as a film of oxidation, showing iridescent colors — blue, purple, green, reddish and bronze shades. It is a good concentrating ore, as it consists almost wholly of quartz and copper sulphide. A small amount of pyrite is present.

The rock samples from Tres Piedras, N. M., are determined as follows: No. 1, light brown, fine grained rock, a typical rhyolite, showing quartz blebs, a few somewhat altered hornblende crystals and an occasional crystal of feldspar, with a few scattering crystals of black mica (biotite). No. 2 is a basic rock (porphyrite), having a slightly schistose structure. No. 3 is a much decayed crystalline rock, originally syenite.

The rocks from Nogal, N. M., are: No. 1., a silicified country rock, possibly originally granite, or some similar rock. It also formerly carried a considerable amount of iron sulphide, and doubtless other sulphides of the base metals, the only ones at present remaining being finely disseminated pyrite. The pyrite has nearly all been altered to iron oxide. This ore may be gold-bearing. It has that appearance. No. 2 is similar to No. 1, but is not so much oxidized. It shows crystals of lead, iron and copper sulphide. No. 3 is an ore, apparently somewhat richer than Nos. 1 and 2. It contains the sulphides of iron, copper, lead and zinc, and has abundant quartz, also a little iron oxide as a result of decomposition of the pyrite. Gold and silver are also probably present in this ore. No. 4 is similar to No. 3, but is less oxidized, and contains a higher percentage of galena (lead sulphide), and chalcopyrite (copper sulphide). This is an ore which should concentrate readily. No. 5 is a siliceous ore, containing much iron oxide—the result of the decomposition of sulphides. No. 6 is syenite, in which occurs iron, copper and zinc sulphide. No. 7 is an altered and silicified crystalline rock, probably something like No. 6. The rock has been altered since its original silicification, by the oxidation of the sulphide minerals. All of the specimens of this lot probably contain gold and silver as well as the other metals mentioned.

The rock specimens from "R," Marysville, Mont., are: No. 1, fine-grained granite, in which there is abundant quartz, both orthoclase and plagioclase feldspar, hornblende and biotite. It would probably be more proper to call this rock grano-diorite. It contains considerable iron-sulphide, which indicates that it is near a mineral vein, as granite seldom contains pyrite at a great distance from a vein, or zone of mineralization. No. 2 is apparently a dike rock—diorite—and is somewhat decomposed. The visible minerals are quartz, feldspar and hornblende. No pyrite is seen in this rock.

The white crystallized rock sample from Randsburg, Cal., is calcium carbonate, commonly called "lime spar."

The sample of ore from Pollock, Idaho, is principally quartz, stained green with copper carbonate. The greater part of the dark mineral is an aggregate of chlorite scales. In several places are small amounts of bornite, a purple colored metallic mineral (sulphide of copper), and at one place a small amount of copper glance, also a copper sulphide. The brownish stains are due to iron oxide.

The rock from Jacksonville, Cal., is quartz with much decomposed ankerite (iron-lime-magnesia carbonate). The dark colored, bright, metallic mineral is specular iron, a variety of hematite. The smooth, greasy-feeling, scaly mineral on one side is chlorite schist.

The rock samples from Dorleska, Cal., are as follows: No. 1, chiefly quartz, carrying pyrite. The structure and general appearance of the rock suggest a zone of mineralization in a granular eruptive rock, probably quartz-diorite or grano-diorite. No. 2 is very similar to No. 1, but somewhat more mineralized. The bright sulphide is pyrite (iron sulphide); the dark mineral is zinc sulphide (zincblende). In No. 3 the sulphides are pyrite and mispickel, with a few very small crystals of galena, zinc and copper sulphide. These latter can only be detected by high magnifying power. Package No. 5 contained two pieces of rock. The float is quartz porphyry. The dark colored piece is a much altered, but more basic, rock, probably originally diorite. It contains much iron sulphide and very little quartz, whereas the float piece contains a large amount of free quartz. No. 5 is granite of rather coarse texture. In this same rock mass, doubtless, different varieties and phases of the rock may be found, but in the samples submitted the entire absence of hornblende removes it from the diorites. No. 6 is a metamorphic rock—graphitic-mica schist. Originally it was a fine sandstone, or mixture of fine sand and clay.

The rocks from Running Water, Wyoming, are: No. 1, mica schist, with a little malachite (copper carbonate). No. 2 is quartzite. It also contains copper carbonate, and in one place a small amount of native silver.

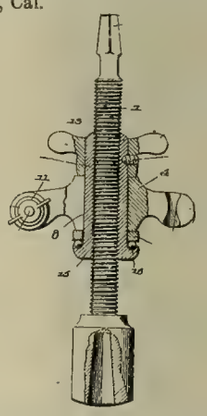
The mineral specimens from Sonora, California, are: No. 1, a dike rock with veinlets of quartz. No. 2, marble (crystallized limestone). It shows free gold. No. 3 is mica schist and calcite. This also shows gold. There are several localities, near the Tuolumne river, in the vicinity of Groveland, where similar ores are found. No. 4 is diorite, almost unaltered. No 5 is quartz, containing a small amount of telluride of gold.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 1, 1905.

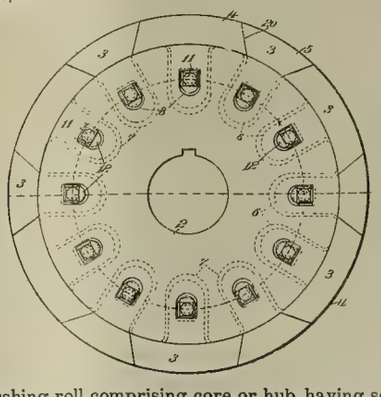
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

DRILLING APPARATUS.—No. 795,450; W. D. Rankins, Modesto, Cal.



Implement of class described comprising threaded shank, collar arranged thereon and provided at lower end with bearing, clamping head entirely encircling and mounted for rotation upon collar and resting at one end upon bearing, lateral arms carried by head, one of which is provided with one of pair of holding chain-receiving recesses, and other of which is cleft through to collar opening, members formed by cleft having opposing faces rabbeted to form second holding chain-receiving recess, and bolt and nut combined with cleft arm to clamp head upon collar, bolt serving as means for connecting holding chain with implement.

CRUSHING ROLL.—No. 795,331; W. Brinton, Highbridge, N. J.



Crushing roll comprising core or hub having series of pockets extending inwardly from periphery thereof, such periphery having concaved formation transversely thereof, plurality of segmentally formed shoes each having transverse convex inner face fitting into concaved seats of core, and inwardly extending lug, and means for securing such shoes individually to core, shoes having beveled coacting end faces, certain of shoes being formed as wedges and others as thrust members, wedges assisting to main tain thrust members in position.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Including the production of coke from by-product retort ovens, which in 1904 amounted to 2,608,229 short tons, the total output of the coke ovens of the United States during 1904, according to the report made to the United States Geological Survey by E. W. Parker, 23,621,520 short tons, against 25,274,281 short tons in 1903. The decrease in 1904, as compared with the preceding year, was 1,652,761 short tons, or 6.54%. The total value of the product declined in much greater proportion, from $66,498,664 in 1903 to $46,026,183, a decrease of $20,472,481, or 31%. At the close of 1904 there were under construction 4430 new ovens, of which 832, or 18.8%, were of the retort or by-product type.

ALASKA.

The Ketchikan Mining Journal reports that the new smelter at Coppermount is now running at full blast and is handling over 250 tons of ore daily. This smelter has been constructed by the Alaska C. Co. The power is derived from Pelton water wheels of 600 H. P. The water is taken from Lake Mellen in the hills back of Coppermount. The company has 30,000 tons of ore in the bins ready for the smelter, and a large force are getting out ore from the mines sufficient to keep the smelter going. From the time the ore leaves the mines till it reaches the hearth of the smelter it is handled by gravity. A railroad 1400 feet long transports the ore from the mine along the ridge of Copper mountain to the top of the aerial tram, which delivers it down to the ore bins above the smelter. From the bins it is conducted by chutes into the furnace. One hundred and fifty men are employed in the smelter and mines. At present the ore is taken from Indiana claim, the ore body of which has been stripped for over 250 feet. H. W. Mellen is president and manager; D. D. Stewart is foreman of the mines, and C. W. Fuller is foreman of the smelter. Besides their property at Coppermount, the company has leased the Rush & Brown property at Kasaan bay, and the ship Richard III is loading 700 tons at that place for shipment to the smelter.

Seward, Alaska, has been connected with the outer world by telegraphic communication. With the completion of the Seward-Valdez cable, the Government has 2300 miles of cable in Alaskan waters. There are hundreds of miles of overland wires, aside from the wireless system perfected by L. D. Wildran between Nome and St. Michael. Messages for Seward over the new cable have to be relayed twice. Going north from Seattle, the first break is at Sitka, where there is a relay to Valdez. At that point the message is repeated to the operator at Seward.

A. Geffeler, manager for the Helvetia and Little Basin companies at Windham Bay, will build an aerial tram to the Windham Bay Co.'s stamp mill, which has been leased to the Helvetia M. Co.

ARIZONA.

Cochise County.

At the Denn-Arizona, at Bisbee, the gallows frame has been finished. One boiler has been placed and another is on the way. The shaft is down 250 feet and progress is being made at the rate of 100 feet per month. The general formation through which the shaft is going at present is an altered sandstone, and it is not expected to get into mineralized ground until several hundred feet more depth is reached. As the diamond drill reached ore at the 900-foot level it will probably be six months before that zone is reached by the shaft. B. M. Pattison is superintendent.——The supplies for the Vantia mill, in the Yellowstone district, have been hauled to the mine, and the mill will be completed within a month. Work underground is not being pushed until the new hoist is running.

Gila County.

The Arizona Silver Belt describes the new concentrator at the Old Dominion, at Globe, as of the progressive crushing type. The first operations begin in the crushing plant at the new shaft where the concentrating ore from the mine is brought into two of the six steel bins. The ore is drawn from these bins onto a belt and from thence passes automatically through the coarse crushers over a picking belt, from which the first-class ore can be sorted, and through a fine crusher and a set of rolls and from thence it drops to another belt where it is carried to the two concentrator storage bins, each holding 210 tons of ore, and there stored. The ore is drawn mechanically from either of these two storage bins by automatic feeders which feed onto another belt regularly, and at any given rate that the mill may demand. The latter belt conveyor takes the ore up a steep incline to the top of the mill and there discharges it into a mixing box where the ore is mixed with water and from thence passes into revolving screens. The ore is classified into various sizes in the revolving screens and in classifiers below them and is distributed according to its size to the various machines on the roughing floor. The two coarsest sizes, viz., the sizes rejected by the §-inch and ⅜-inch screens, respectively, drop into two bull jigs and after the very coarse metal is extracted, the tailings pass automatically to the finishing rolls and are again elevated until they pass through the ⅜-inch screen. All sizes of material from the ⅜-inch size down, excepting the finest slimes, are sized and passed to the main roughing floor of the mill where they are concentrated in seven jigs and the six Wilfley tables. The concentrates from this main roughing floor discharge automatically and unite with the concentrates from the bull jigs and pass to the storage bins for concentrates. The tailings rejected by the machines on the roughing floor are collected and crushed finer, if necessary, in two 6-foot Chilean mills. The reground tailings are then classified and are passed to the machines on the finishing floor for final treatment. Automatic devices are used to remove the water from the coarse tailings and to thicken the slime pulps before they pass to the finishing floor and the water thus obtained is returned for use in the mill. The finishing floor is equipped with nine Wilfley tables for the coarser sands and eighteen Frue vanners for the finer sands and slimes. All concentrates from this floor pass by gravity to an elevator and are elevated and thrown into the stream of concentrates from the upper floors and pass to the storage bins from which they will be drawn into railway cars and taken to the smelter. From this description of the process it will be seen that from the time the ore is thrown onto the upper belt until the time that the tailings are turned out of the mill and the concentrates delivered into the storage bins, everything is automatic and there is no shoveling or wheeling of any kind. The mill building is of steel with steel shaft supports and steel supports for the revolving screens. The foundations are of concrete and all heavy machines are set close to the ground upon strongest foundations. The mill is designed to have a capacity of 300 tons per day. Feed was turned on the mill on the afternoon of July 30 and it ran steadily until the end of the shift. There was no time to regulate the flow of water and it has taken a few days to get the mill started to work regularly.

Mohave County.

(Special Correspondence).—The West Gold Road Co. has resumed active operations. New mine and office buildings will be put up, a new hoisting plant installed and a double-compartment shaft begun. Considerable new hoisting and sinking machinery will be bought this season. Jno. M. Wright is manager, J. D. Spargo superintendent.

Acme, Aug. 8.

At the Minnesota-Connor mines, at Chloride, seventeen men are at work. ——G. H. Hooper is working the Midnight and Pinkham mines at Chloride.——Near Pilgrim camp, at the Dempsy-O'Dea property fifteen men are at work on the mine and the shaft is down 275 feet. ——At the Azalia mine seven men are at work.——R. C. Walker, superintendent of the Cerbat Mountain M. Co., reports that sinking below the 175-foot level is under way.

Pinal County.

Development at the Buckeye mine, in Twin Butte district, is progressing rapidly, the shaft being now down 375 feet. The company is making preparations to start the smelter. —— A Pittsburg company has taken over the Midday copper claims in Saddle Mountain district. T. F. Weeden, the superintendent, has received instructions from the company to purchase ground at the river along the line of the Phœnix & Eastern Railroad for a site for a 500-ton smelter and concentrating plant.

Santa Cruz County.

R. E. Doan, of Los Angeles, has bought the Gringo mine of J. Parks, in Temporal gulch, 3 miles from Patagonia. He proposes to put up a 50-ton mill to treat the low-grade gold ores.

Yavapai County.

(Special Correspondence).—It is reported that Dr. E. B. Perrin, owner of the onyx quarries 45 miles northwest of Prescott, has made a contract with the Denver Development Co. to do $80,000 worth of work on them, and other contracts with Chicago people to take the entire output. A narrow gauge railroad is to be built from Seligman to the quarries.

Prescott, Aug. 8.

(Special Correspondence).—The Harryhousen claims, adjoining the United Verde on the north, have been taken under bond by D. N. Bartholdi and associates, who are making preparations for the development of the property.

Jerome, Aug. 7.

The 10-stamp mill at the Golden Idol at Cherry creek is said to be nearly finished. C. K. Tibbetts is superintendent.

A gasoline blower and 1000 feet of air pipe have been put on the Buffalo M. Co.'s mines on Berry creek. The tunnel, which is now in 1000 feet, will be driven 500 feet farther.

The Jeanette-Arizona Gold M. Co. is working claims on the Santa Maria, 8 miles southwest of the Sultan mine, near Hillside. Superintendent Carbaugh has two shifts drifting from the shaft, which is down 400 feet. ——At the Mineral Hill camp, near the Jeanette-Arizona Co., a steam hoist has been put in.——The Eagle Gold & Copper M. Co. is working southeast of Martinez under the direction of O. Jennings.

Yuma County.

The 20-stamp mill at the Soccorro mine, at Harrisburg, is working twelve hours per day. B. J. Quinn has temporary charge of the mine, and also has charge of the cyanide plant at the Harqua Hala, employing six men. It is reported that the water is to be taken out down to the 600-foot level and the mine developed.——J. B. Martin has leased the Desert Queen mine to the C. H. Pratt Co., and Hall Bros. are doing some work on it.—— The Winzedale M. Co., under the management of Hanna & Young, are putting up sampling works at Winzedale and are developing a water supply. Water has been found at a depth of 129 feet. Mining properties near Cunningham pass, 8 miles from their works, are being developed.

CALIFORNIA.

Calaveras County.

(Special Correspondence).—There is more interest being taken in the ancient river beds in this district than in many years heretofore. There are several channels under and near the town of Mokelumne Hill which are mostly buried by the lava caps. In early days these channels are reported to have yielded large returns and to have given employment to several thousand men. There remain remnants of old channels unworked and the upper gravel of channels worked in the 50s which was considered too poor to work at that time, but which will pay well now. These channels are mostly buried under Stockton ridge to a depth of 250 to 300 feet. The old workings are for most part inaccessible, but new shafts have recently been sunk and the gravel channels again exposed. Some new work is planned, and it is intended to explore and drain several of these old channels through the medium of a tunnel from the west side of Stockton ridge. This tunnel, known as the Hector, is already in several hundred feet. The principal channels under Stockton ridge are the Stockton ridge channel, Chile gulch blue lead, the Corral flat, or French hill channel, and further south the Duryea and Concentrator channels. In addition to these there are believed to be some other channels, of which but little is known at present.

Mokelumne Hill, Aug. 7.

El Dorado County.

At the Mt. Pleasant mine, near Grizzly Flat, the mill is running on fair ore and the mine is looking well.—— It is reported that the first payment has been made on the Zimmermann mine, Pacific district, and that work will be resumed soon.——At the Alcimento mine, Smith's Flat district, Superintendent C. Henson has opened up and repaired 700 feet of tunnel.

Kern County.

At the Butte mine at Randsburg it is reported that a 14-foot ledge has been struck at the 600 level, a part of which shows assay values of $100 a ton.

The Baltic mine, near Randsburg, has been sold to an Eastern syndicate. E. R. Abadie will have charge. They have ordered a 25 H. P. gas engine for hoisting and will sink 500 feet on the ledge. They have also ordered a 50-ton cyanide plant. The water will be developed from Cuddaback lake.

Nevada County.

Superintendent Kendall expects to have the machinery in place at the Banner mine, near Nevada City, by August 15th, when pumping will be commenced. The company has put in steam powor, being unable to get water. It is possible electricity will be put in later. The shaft is to be sunk from the 700-foot level to the 1200-foot. C. C. Weisenburger has charge of the placing of the plant.——The mill at the Grey Eagle mine, near Maybert, has been started again.

At the Empire mine at Nevada City, the crew at the 3000 level struck the main ledge, for which it has been running a crosscut for several months. Drifting will at once begin and an ore chute will be put through. It is the intention also to equip the level with a more powerful pump.

Mariposa County.

The Exchequer M. Co., which owns mines above Merced Falls, is about to put in machinery and build a dam on the Merced 7 miles above the falls and put in a power plant.——At the Houghton mine, north of Hornitos, a new 10-stamp mill is being put up.

Placer County.

(Special Correspondence).—The recently completed shaft of the Hidden Treasure gravel mine at Bullion is being timbered. A sawmill is to be put up at the collar of the shaft, and hereafter all timber will be supplied through the shaft. The tunnel is being straightened and 35-pound rails are being laid to replace the lighter ones formerly in use. A new electric locomotive to be put in will increase the output. H. T. Power is superintendent.

Bullion, Aug. 9.

A fire at the Whisky Diggings mine, northeast of Lincoln, August 4, destroyed the hoisting works. It is reported that work will be resumed soon.

Shasta County.

It is expected that the new 5-stamp mill of the Middle Creek G. M. Co. at the Dowbrowsky mine, near Shasta, will be running by September 15.——D. J. Phelps has been making arrangements to resume work on the Mt. Shasta mine on Clear creek, west of Shasta.

Sierra County.

At the Alaska mine at Pike City the company has decided not to open the old shaft, but will sink a new one close by. The old shaft is 700 feet deep, and the old company had trouble in contending with the flow of water. The present company will have pumps that will be able to handle the water. There is a new 20-stamp mill on the mine.

The Alaska mine at Pike City is being opened up under the direction of Superintendent George St. John. The company has decided not to open the old shaft, but will sink a new one close by. The machinery will be put in as quickly as it arrives. The old shaft is 700 feet deep, and the old company had trouble in contending with the water.

The Forest City M. Co. is developing Chipps Ridge, between Wolf and Kanaka creeks.

At the Rainbow mine, near Alleghany, the old flume is being replaced with a new one preparatory to starting up the mill. J. Clinton is in charge of the work.——The Marguerite mine, 2 miles west of Sierra City, is being reopened by a company headed by J. E. Westall, who is is charge of the work. The 4-mile Marguerite flume is being rebuilt and will furnish power for pumping and milling.

Siskiyou County.

Lack of water has caused a large number of Siskiyou county mines to close down until the fall rains come on. ——In the Oro Fino district D. Carter is sinking on a ledge adjoining the Gardner mine.

Trinity County.

Superintendent Charles Dobler has seventy-five men at the Fairview mine and mill at Minersville. Mill Foreman A. H. Philbrook is keeping twenty stamps dropping.——Dr. Johnson and M. W. Stover, who have a bond on the Beaudry property at Minersville, will put in a hydraulic elevator on the low ground. The ditches give a pressure of 350 feet.

Yuba County.

Four new mining dredgers at the Yuba Consolidated Gold Fields are being equipped with machinery and will be in operation this fall. The hulls have been com-

pleted and floated. The pit is ready for two more and timbers are being framed for them. The two dredgers being built for the Marysville Gold Dredging Co. are well along and all ten of the machines, including the two already operating, the four now being equipped, the two just commenced and the two being built by the Marysville company will all be working on the training walls on each side of the river for the Government by November 1.

COLORADO.

Boulder County.

The Lulu B. mine and mill, operated by the Utica Hill M. & M. Co., has been working near Ward under the management of J. McKimmery. The shaft is now down 450 feet. Levels have been run at each 75 feet, all of which show large bodies of ore. Their 10-stamp mill, 1½ mile north of Ward, is running steadily.——J. L. Lee is unwatering the Morning Star mine, near Ward.——The Old Humboldt mine at Ward is being worked under the direction of W. T. DeCamp.——The Sound Currency M. Co. has been sinking a shaft on their property north of Ward. They will put in a hoisting plant. —— The Myrtle M. & M. Co. has received word that its new Howell-White roaster will be shipped by Aug. 11.

Denver County.

The Western Association of Technical Chemists and Metallurgists hold a general meeting in Denver, Sept. 5 to 7. H. C. Parmalee is secretary.

Clear Creek County.

The new concentrating mill of the Waltham M. & M. Co., on Chicago creek, near Idaho Springs, is in operation. The plant was briefly described in the issue of Aug. 5. An illustration of this mill and its surroundings appears on the front page.

At Idaho Springs the holdings of the International Gold Mining Co., the Banner Development Co. and the Colorado Development & Investment Co., which were taken over by the Banner Consolidated mines, have been consolidated. The three companies owned forty-nine claims on the ridge, between Clear creek and Trail creek. The property will be opened up at depth by means of the Rockford tunnel. Boilers, air compressor, blower and drills are to be put in at once. The tunnel has been driven 1000 feet and will be continued to the Donaldson vein, where it will attain a depth of 1600 feet. H. A. Reidel will have charge of the operations.——The Crowfoot crosscut, of the Capital Prize group, is in 1900 feet on Griffith mountain, near Georgetown. Manager W. Cooper intends to put in two more machine drills. ——A. M. Hill, owner of the Julian property, on Lincoln mountain, near Georgetown, having arranged for the resumption of work, will drive the tunnel on the Julian claim, which is now in 100 feet.

The Newhouse tunnel has placed an order for ten new tram cars and a motor.——The Sun and Moon and Saratoga are getting ready to use a large increase of power and will push their development work through the tunnel. The Ora M. Co. has begun work with air drills, drifting on the Edgardine lode in a lateral from the Newhouse tunnel.——The Queen Francis Co. has put miners to work, cutting a station and switch off from the tunnel, preparing to drive a lateral on the Queen lode; and work will begin on the Adduddell lode early this month in the Newhouse tunnel.

The Little Richard M. Co. is running its tunnel to cut the Lexington vein, near Idaho Springs. This tunnel is now under the Lexington territory, but the vein, which has a northward pitch near the surface, has turned and pitched toward the south, making it necessary to drive the tunnel much farther than was expected at the start. Work has b en hindered by bad air, but this has been overcome by a suction fan. W. J. Morgan of Milwaukee, Wis., is manager. G. L. Bingham of Idaho Springs has charge of work. —— The Frances M. & M. Co. will work the Queen vein, near Idaho Springs, through the Newhouse tunnel. —— At the Torpedo tunnel, in Spring gulch, operated by the Idaho Springs Gold Producing Co., J. C. Hull of Idaho Springs manager, hand work has been discontinued and machiney put in. —— W. M. Kirke of Idaho Springs, who has been working the Castleton mine since the first of the year, is putting in new ore plates preparatory to a heavier output. —— Operations have been started at the King mine on Fall river, near Idaho Springs. W. H. Moore has charge.——J. G. Roberts, W. G. Arkills, J. Nelson, M. C. Potter, E. R. Lumley, J. W. Anderson and R. R. Graham, all of Idaho Springs, have leased a block of ground on the Columbia mine on Little Mattie mountain, and are preparing to sink the shaft another hundred feet.

Gilpin County.

The Hot Time Transportation, Tunnel, Drainage, Mining & Milling Co. has been formed with W. L. Bush as president; J. R. Spear, vice-president; G. K. Kimball, secretary-treasurer and manager; all of Idaho Springs. The company will work mining property lying between the line of the Newhouse tunnel and the Old Town mine, and drive the lateral connecting the Old Town workings with the Newhouse tunnel. Work has been started with machine drills. The distance to be driven is 4000 feet and will require eighteen months to complete. The driving of this lateral will benefit the Russell Gulch section, as its course will be almost directly under the lowest part of the gulch the entire distance. It is believed that it will ultimately drain every mine in the immediate section through which it traverses. The Old Town shaft is 1500 feet deep on the pitch of the vein, and the lateral will cut beneath the bottom of the shaft.—— The Dump mine, on Bobtail hill, is being operated under a lease and bond by M. Dalpez & Co. of Central City. A new shaft building and machinery has been put in. Sinking operations have been completed, the shaft being down 350 feet, at which depth drifts have been commenced on both sides of the shaft. Drifts are also being extended on both sides of the shaft at a depth of 280 feet, where there is a good sized ore body and regular shipments are being kept up.——The Never Sweat mine in Lake gulch is being operated under a lease and bond by J. B. Chatterton of Central City, the owners being H. M. Orahood of Denver and A. B. Drake of Central City. Sinking is being done, and drifts are to be run when down 100 feet. A whim is being used for present hoisting purposes, but if the indications continue a steam hoist is to be put in, as deeper operations will follow.——Doble & Co. are working the Pederson mine in Gregory district under a lease, at the 250-foot workings.——Ellmann & Co. have been timbering a new shaft east of the main shaft on the Susan Mary mine in Lake gulch, and will sink to a depth of 125 feet, when they will make connections with the main level from the deep shaft. They expect to put in a whim for hoisting.——The shaft of the Clay County mine, in Lake gulch, is down 700 feet. The 300 west level is being cleaned out.——The New National Tunnel M. Co. is sinking at the Caledonia shaft and are down 520 feet. The intention is to sink this shaft to the tunnel level for air connections as well as to take out the ores through the tunnel level. G. W. Adams is superintendent.——The Ontario-Colorado Gold M. Co. is employing fourteen men at its O'Neill mine in Gregory district. Two drifts are being run on the west side at a depth of 464 feet and stoping is also being carried on in both places. Milling and smelting ores are being taken out each drift and a winze is being sunk for ventilation and for development purposes. H. Bowden is in charge.

A. E. and W. Hampson, who have been operating the tailings plant at the Smuggler-Union mills, have surrendered their lease on the same and will hereafter operate in Black Hawk. They will get the tailings from eight mills for treatment without the payment of any royalty whatever, compensation for the privilege being only ground rental. Their plant will be equipped with sixteen Wilfley tables, six Frue vanners and 150 canvas tables.

A. B. Sanford of Denver is reopening the old Mann and North Star claims, in Vermillion district, 5 miles west of Central City. The main shaft on the North Star is 314 feet deep, whence a level is being driven to the west to get under the ore known to exist in the upper workings. A new mill is planned to treat the ore by plate amalgamation, concentration and cyanide.

The Victoria group of the Star of Gilpin Co. is being worked under the direction of W. L. Shall. The property is 2 miles from Rollinsville. The main shaft is now down 150 feet and an upraise is being made. A new shaft is being sunk 150 feet from the main shaft.

Jefferson County.

(Special Correspondence).—Ground has been broken for the Guggenheim Hall at the School of Mines. The money for this building, which amounts to $75,000, has been donated by S. Guggenheim. The corner stone of the building will be laid Sept. 30, 1905. A new power house and assay laboratory are just being completed at an expense of $50,000.

Golden, Aug. 7.

H. J. Reiling, president and general manager of the National Gold Dredging Co., operating the gravel bars on Clear creek, near Golden, states that he is handling with two dredger boats 75,000 cubic yards of dirt per month. Discovering that a considerable part of the flour gold was escaping, he has put in a Pierce amalgamator as an experiment, and is also having it tested by the jigging process at one of the testing plants in West Denver. About 1½% of the total yardage handled is black sand, which contains, in addition to flour gold, considerable quantities of monazite. The black sand is saved for separate treatment hereafter when the flour gold and rare minerals will be extracted.

Lake County.

With the increasing demand for zinc and the success attained by the new Yak tunnel it is probable that another zinc mill will be working in Leadville inside of two months. Pittsburg people are behind the enterprise and the mill will be built near the Norton sampling works, and H. H. Norton will have charge of it. At present the mills in the camp are handling only 25% zinc, but it is stated on good authority that the new mill will handle a much lower grade at a fair profit.

Stewart & Thompson of Leadville have commenced work on the Flagstaff group in Bosswell gulch.

Low-grade siliceous ore has been found in the Gold Basin, belonging to the Big Four M. Co., Jonny hill, Leadville, through the workings of the Fannie Rawlins. T. D. Kyle and associates have a lease on the ground and are shipping fifty tons daily from the 360-foot level.

La Plata County.

At the new Bonnie Girl M. & M. Co.'s 50-stamp mill on the La Plata river, near La Plata, the ore is to be carried from the mine to the mill by a 4600-foot Bleichert tramway, with a drop of 1100 feet. The longest single span is 700 feet. The ore is distributed to the ore bins, 1500 tons capacity, by a 20-inch belt, 85 feet long, fed from a hopper. The mortars, weighing 6200 pounds, placed 18 inches above the floor, are set on blocks of crushed stone and Portland cement, the top dimensions of which are 9 feet by 4 feet 9½ inches and the base 7 feet by 4 feet 9½ inches. The mortars are lined with manganese steel. Suspended feeders fitted with manganese-lined removable spouts feed the ore to the batteries, where it is crushed through 30-mesh screens. The fifty stamps each weigh 900 pounds and will drop from 6 to 8 inches at the rate of ninety-five per minute. To every five stamps there is a friction clutch. Only outside amalgamation is to be practiced, two plates being 3 feet in length and one 4 feet. The mill water supply comes from Tirbieco gulch, 1200 feet above the mill, and is delivered to the mill in a 12-inch pipe under a 48-foot head. Manager C. L. Buckingham has designed the mill and electric power plant.

The Copper Age group, 2 miles from La Plata, is being worked by F. M. Crowell and C. Roundtree. The main tunnel is in over 200 feet.——The Chief M. Co. is working five claims near La Plata, under the direction of L. L. Swift.

Mineral County.

(Special Correspondence).—The Creede United Mines Co. have not been running their big mill full capacity for some time on account of scarcity of ore, but the capacity of the mine is increasing and it will be but a short time before they will be turning out the full capacity of the mill. The camp is better than for several years and it is thought within a few months the output will be increased.

Creede, Aug. 5.

Ouray County.

W. G. Brown, of the Security M. Co. of Ridgway, is expected to start the mill by Sept. 1.——J. S. McCluskey and W. E. O'Brien, who are leasing at the Grand View, below Ouray, have struck gold-copper ore in the new tunnel which was started between the mill and shaft house levels.

Park County.

In the lower Tarryall district, near Wayman, north of Cripple Creek, J. K. Vanatta, president of the Apex Copper Co., owns prospects. Mr. Vanatta has sunk two shafts on the Apex. The main shaft was sunk to the 250-foot point. There lime was crosscut for 125 feet. The new shaft has been put down 130 feet. It is proposed to continue one of these shafts to a depth of 300 feet. Emil Erickson is superintendent.——At the Star group of the Haymen Co., Manager Frank Clancy has sunk the main shaft 270 feet.

San Juan County.

The railroad being constructed from Howardsville up Cunningham gulch will have a beneficial effect upon the development of the mines in that section. It will pass the Old Hundred group first, then the Green Mountain and the Pride of the West, the latter operated by E. Smith and associates, who are putting in a big power plant with a 400 H. P. Leffel turbine. The Green Mountain Co. will build a 3000-foot tram and put in twelve Rand Slugger drills for opening up their property to supply their 200-ton mill. The Old Hundred people have ordered a Corliss Imperial Rand compressor for their mine. —— N. R. Bagley has let a contract to drive a 5000-foot tunnel into the property which he is managing, and expects to order a compressor plant for that work. —— J. Terry has opened up the Sunnyside mine and is doing about 500 feet of development work every month with machine drills. —— The Gold Prince mill, being built at Animas Forks under the supervision of O. O. McReynolds, will probably be completed by Jan. 1, 1906.——At the Old Hundred mine Manager R. W. Davis is pushing the mill construction to get under cover before the beginning of winter. —— I. C. Boss, inventor of the Boss method of stamp milling, is erecting the mill at the Grand Mogul. —— The Pass M. Co., operating the Champion mines, Sultan mountain, are putting up a Bleichert tramway 1400 feet long, and placing Rand drills for the more rapid development of their properties.

The Animas Power Co. has its electric plant at Rockwood, between Silverton and Durango, on the Animas river, almost completed and the stringing of wires into the Silverton district has commenced. The work is under the management of W. R. Allen of Colorado Springs. To reach Animas Forks and the headwaters of the Animas river, Gladstone and the tributaries of Cement creek, together with the side lines to the Silver lake and other large properties in the county over 60 miles of primary aluminum wire will be required, and of secondary wire 150 miles will be required to accommodate the mining properties that have already signed contracts to use the Animas power. The date set for turning on the current is Oct. 1.

The Silver Ledge mill at Silverton is shipping two cars of zinc concentrates to Denver and three cars lead-iron concentrates to Durango each week.——It is reported from Animas Forks that the Dewey mine in Hurricane basin has again been started up by Ouray parties.—— Matson & Slattery have resumed work at the Queen City property in Ohio gulch.——At the Aspen mine, on Round mountain, sixteen men, under the management of J. O. Campbell, have been cleaning out the old timbers and debris in the tunnels.——The Hamlet M. Co.'s new 50-ton mill is producing several cars of concentrates a week. It is on the Animas slope of Middle mountain, alongside of the Silverton Northern Railroad track. C. Dale, the builder, is improving the jigs.——The Hercules management at Silverton are sinking a shaft on the Little Dora vein 1300 feet from the portals of the lower tunnel. The shaft will be sunk to a depth of 250 feet. The main tunnel is in 3500 feet and is still being driven ahead. Since beginning operations in the spring, Manager Thomas Kane has been developing and blocking out ore bodies, with intention of having mineral for a continuous run of the mill.——At the Champion mine on Sultan mountain, near Silverton, the Ross M. Co. are constructing an aerial tramway 1400 feet in length, from the mine down to the D. & R. G. Railroad track. A 6-drill air compressor will be put in at the foot of the hill.

San Miguel County.

A rich strike is reported in the lower workings of the Japan mines, near the Tomboy, in Savage basin, 5 miles from Telluride. The company has decided to abandon the old mill in Savage basin, near the Japan mine. A new plant will be constructed at Pandora, 2 miles from the Japan group, by the Japan-Flora M. Co. Mine and mill are to be connected by an aerial tramway.

Nelson, Kirby & Reed, all of Telluride, will operate the plant at Pandora.——In the Smuggler-Union mills at Pandora they have 110 stamps dropping. In the new 60-stamp mill thirty stamps are pounding on the ore of King & Lindsey, lessees of a large portion of the Smuggler-Union mines, and thirty on the ore of Townsend & Bancroft. In the old 80-stamp mill only fifty are falling. Of these thirty are on the ore of Wagoner Bros., lessees of the Sheridan, Smuggler and Union dumps and the 76 claim, and twenty on the ore of King & Lindsey.

Summit County.

(Special Correspondence.)—Summit county is doing more deep mining than ever before in the history of the county, especially in the Ten-mile district. This district begins at Fremont Pass, north of Leadville, and runs from the headwaters of the Ten-mile to where it empties into the Blue at Dillon. In the upper Ten-mile at Kokomo the two most active properties are known as the Wilfley and the Breene. These mines are reported as shipping about 100 tons of ore per day each. The ore carries approximately 25% lead, 30% zinc and 30% to 40% iron. At Frisco four crosscut tunnels are being driven. The King Solomon mine, illustrated on page 110, is equipped with boiler, 8-drill Rand compressor, and is putting in electric light plant, and expects to drive the tunnel 2000 feet farther, making 2500 feet in all. In going

this distance they expect to cut ten veins which are known to exist at the surface, and from which considerable ore has been shipped heretofore. The North American and Mary Vernon properties belong to parties living in Memphis, Tenn. It is understood they have made arrangements for a power plant, to be erected about half way between the Mary Vernon and North American, which will supply air for both mines. A contract has been let to run a tunnel on the North American 3000 feet and on the Mary Vernon 2000 feet, the company to furnish the power, air and light, Mr. McAllister, at Frisco, resident manager of the properties. The other tunnel that is being driven is on the Mint property of the Mint M. & M. Co., in Ophir mountain. Same is now in over 500 feet and will be continued. The company intends putting on a plant of machinery, including electric light plant, air drills, etc. F. E. Wire, Libertyville, Ill., has charge of the operations. The Chief Mountain Mining Co., in the district, own ten or twelve claims, from which several tons of ore run well in gold, silver and lead. An adit tunnel is being driven on one of the veins, which is now in several hundred feet. It is the opinion of prominent mining engineers as soon as some of these tunnels now under way are completed, it will be the means of opening up some good ore, and that mining on the Ten-mile will no longer be in the prospective stage, but will be one of the leading districts of Colorado.

Frisco, Aug. 8.

Teller County.

J. Wellington and associates have secured a lease on block 190, the Lucky Gus claim, of the Stratton Cripple Creek M. & D. Co., and are working it. A shaft on the Lucky Gus is 1000 feet deep, but the new operators will commence work on the upper levels.——Fitts & De Masters, operating the Deerhorn property on Globe hill, Cripple Creek, have a new body of ore.——Operations are being pushed through the Pinto shaft of the Free Coinage Co. property on Bull hill and in the town of Altman.——Moon and associates have a lease on the Nightingale property on Bull hill and have put in machinery, and will push operations throughout the shaft, which is now 300 feet deep.——The Golden Cycle Co. has laid off between sixty and seventy of their machine men while new compressors are being put in. The company has received two 10-drill air compressors. The company was formerly operating eighteen drills. Heretofore the Golden Cycle Co. has secured its air from the La Bella plant.——The Gilpin & Cripple Creek Co. is working in the Little Pearl shaft on Bull hill. The company has leased the Atlanta property to R. P. Russell.

Preparations are being made by lessees to put in a 100-ton cyanide plant on the Des Moines property, on a south spur of Gold hill, near Cripple Creek.——There are six or eight cyanide plants in operation in the district and all of them are recovering large amounts of gold each month.——The mill on the Los Angeles mine, on Bull hill, is completed and the company is treating between forty and fifty tons of ore a day that is averaging $5 to the ton in gold.——Next month the Little Giant Co. will commence operations in Pony gulch.——The Empire State shaft of Bull hill, Cripple Creek, is being sunk from 800 feet to the 1300-foot point.——At the Mary Nevin C. C. Jackson and associates, lessees, have arranged for a 12-drill compressor at the Nevin shaft.

IDAHO.

Boise County.

President J. J. Oberbillig of the Twentieth Century M. Co., operating in the Black Hornet and Pearl mining districts, states that during the past eight months he has been at work on a tunnel being run to cut three ledges. The tunnel is in 440 feet and has cut four of the ledges. A 20-ton cyanide plant will be put up this fall, the capacity to be increased as development requires.

Custer County.

To open up the Seafoam and Greyhound districts Gov. Gooding states that the State will furnish half of the $4000 which it is estimated the road will cost. The miners there will have to do the rest. It is proposed to make a contract with the miners to build half the road under the supervision of the State and on a survey made by the State, as it will be necessary to have a road equally good at all points. The proposed road will start at Wagontown on the Ketchum road, cross Vanity summit, run down Vanity creek to Rapid river and pass down the latter stream to Float creek. It will be 12 miles in length.

Idaho County.

The Crooked River M. & M. Co. is building a flume to their properties, near Oro Grande, to replace the ditch now in use. It is hoped to continue operations during the winter. Elevators, classifiers, distributors and pumps are to be put in the mill.——J. F. Powers, secretary of the V. & O. M. Co., at Oro Grande, expects that the new cyanide plant will be finished by the end of the year.——W. I. Sweet of Long Branch, New Jersey, says that the Idaho Consolidated Little Giant M. Co., of Warren, is preparing to put in an electric power plant for the operation of their mine. The company has a 5-stamp mill. H. Sheller, of Warren, is the president and manager.

Owyhee County.

H. M. Stevens, superintendent of the Rich Gulch Co. mines, reports that a new strike has been made on their claims near Silver City.——Electricity is to be substituted at the Cumberland mill, on War Eagle mountain, near Silver City, for the present steam power.

Shoshone County.

During the portion of last month that Richard Anderson was operating the Rex mine, formerly the 16 to 1, under lease, the royalties of the company are said to have amounted to $2000. About 200 tons of concentrates were shipped, which assayed 62% lead and 30 ounces in silver. The ore that was milled was taken from the stopes between two levels. The ore as mined is said to carry 14% zinc, but the value of this metal is not saved.——Low water has caused the Black Cloud mine and mill to close down, throwing seventy-five men out of employment. A Pittsburg corporation has been operating the property for several months. Until there is an increase of water in Nine Mile creek only a small force of men will be employed on development work. This is the second property that has been forced to suspend operations this summer on account of the lack of water. The Rex mill closed down last week for this reason.

Washington County.

The Ladd Metals Co. is pushing work on the smelter at Landore and have commenced on the brick work of the reverberatory furnace. They have fifty men at work.——C. W. Jones is working the Peacock mine, near Landore.

MICHIGAN.

Houghton County.

The Adventure mine has been closed on account of a strike. The company wished to save time and expense of hoisting the men to the surface at the noon hour, and announced that lunches would have to be eaten underground in the future, whereupon the men walked out. No extra labor will be required, the company says, to resume when the men return to work on their terms.

Keweenaw County.

Sinking at the Allouez is below the fourth level 50 feet. The management states that there has been no change in the quality of the lode as the sinking progresses. The beginning of stamping operations at the Centennial mill on Allouez rock is due to start. The shaft has three compartments, with 2-ton skips and hoists good for a depth of ½ mile. Owing to the steepness of the incline shaft, back rails of 6x10 inch timbers are set so close to the wheels of the skips that their flanges can not leave the steel rails, the wooden timbers really serving as guides. At the change of angle from 80° to 38° on reaching the lode, a single idler with wide flange cares for the cables passing at either end. In order to save pumping charges on surface water entering the mine, H. J. Stevens, in the Copper Handbook, says that a gutter has been cut around the shaft leading to an opening 36 feet long, half winze and half drift, used as a sump.

MISSOURI.

Jasper County.

The Maud L. M. Co. has completed a new 200-ton mill on its lease on the Leonard land at Chitwood. It is equipped with electricity, except the air compressor, which will be driven by an 85 H. P. gas engine.——The Three C M. Co., operating in Chitwood, is ready to build a new mill. The company is under the management of C. A. Morsman.

MONTANA.

Broadwater County.

The new concentrator at the East Pacific, near Winston, is finished. There are 20,000 tons of good concentrating ore on the East Pacific dumps which will be worked, after which second-class ore from the mines will be put through. F. A. Taylor is superintendent.

Fergus County.

The new cyanide plant for the Maginnis mine at Maiden has been completed and the mill remodeled.

Granite County.

The Granite Bi-metallic mines at Granite have been closed by President P. A. Fusz.

Jefferson County.

The Basin Reduction Co. are building a new tail race with a system of tanks which will quickly gather all the tailings which can then be dumped into the cars. A race was built with lateral sluice ways, the water being conducted by these directly into the railway cars, allowing the tailings to settle, the railway company then hauling the cars to some of their high trestles near the Wickes tunnel, where they are dumped. But this system has proven ineffectual and was only built for temporary purposes or until the tanks now under construction could be put in. The tail race will be built over a series of tanks having a dump bottom. The tanks will catch all the tailings and these will in turn be dumped into the cars direct. The plant will be inclosed in a building, which will be steam heated to avoid freezing during the cold weather. The company contemplates improvements in their settling dam system to gather the slimes.——A. B. Keith is working claims near Clancy.——H. Williams is working the Sierras mine, near Basin, and shipping ore to the East Helena smelter.

NEVADA.

Elko County.

Work has been resumed at the Wardell Iron mine, near Wells, by the owners, C. O'Neill and G. R. Vardy. It has been found that the ore is valuable for fluxes, and it is said the owners have concluded an arrangement with the United States Smelting Co. whereby a good market is furnished.

Esmeralda County.

The Gold Bar M. Co. of Goldfield is said to have secured 1000 acres of coal land near Coaldale, 47 miles northwest of Goldfield. In a 5-foot blanket vein coal that will do for steam purposes has been proven. Special fire grates will be built for the boilers for its consumption. Water has also been developed on the ground and it is estimated that it can be pumped to a mill at a cost of three cents for each 1000 gallons. An electric railway may be constructed from the mill to Goldfield. It was found that it would take about 60 miles of track, as all the heavy grades will be avoided, thereby saving a large amount in the grading expense and the power required to pull the trains. Electric power for mines and lighting purposes will also be furnished. It is reported that the company will put up a 500-ton cyanide and chlorination plant. J. M. Hower, manager of the Dorcas mill at Florence, Colo., and E. F. Browne are interested.

The Wisconsin mine at Lida has been sold by P. Kiser to the Nevada Exploration Co., J. B. Croak, manager. A double-compartment shaft is to be sunk and new machinery is to be put in.

Lincoln County.

Contracts are to be let by the Gold Coin M. Co. for sinking the Sazerac shaft to the 300 level, for drifting 100 feet south at the 200 and for drifting north and south at the 300 when reached. The mine is at Dupont camp in Searchlight district. Carl Andersen has charge. The present hoist will be replaced by a 25 H. P. hoist as soon as the 300 level is reached.——Work will be started on the Mountain View claim of the Wynopa group, belonging to the Gold Coin M. Co., 1½ miles southwest of the Sazerac.——Water struck in the bottom of the 200-foot shaft of the New Era mine, near Searchlight, has stopped work until a 6-inch pump can be put in. The shaft is to be sunk to the 350-foot level.——A special postoffice has been established at Nelson, Eldorado canyon, with P. A. Blair as postmaster.

NEW MEXICO.

Grant County.

At Silver City the Comanche M. & S. Co. will build a 200-ton concentrator and a briqueting plant. The reverberatory and blister furnaces have been finished.——The Ernestine M. & S. Co. has been unwatering the Mogul and the Pinos Altos Town shaft preparatory to working these properties. A steam hoist is being put on the Pinos Altos, and a contract has been let for mining the ore, on a tonnage basis.——As soon as the water is lowered to the 500-foot level, the Gillette will start work with a hoisting equipment and a permanent pumping plant that will drain all the properties on the Pacific vein.——Ore is being taken from the Hearst shaft. The air shaft to connect with the tunnel level will be finished by August 15, when the force in the mines will be increased.

Otero County.

The Southwest S. & R. Co. intends to begin work on its proposed smelter at Jarilla on September 1.

OREGON.

Baker County

J. Cheyne, who has charge of the work in the crosscut tunnel on the Morning mine, near Greenhorn, says the miners are contending with a large flow of water and with running ground, but are making progress.——The Humboldt mine, near Greenhorn, is replacing its small gasoline hoist with a larger steam one.——The owners of the Spero group, near Greenhorn, have resumed work.

Manager M. E. Bain of the Overland mine, near Cableville, says his deep work is entering the zone of the shoot he proved at the surface.——The Royal Winchester M. Co. has been organized by G. Kellogg and associates of Atlanta, Ga., to develop a property on the John Day side of Cable Cove, near Cableville.——M. F. Muzzy and D. Cahill of the Cracker-Oregon Co. of Bourne have resumed operations.——Superintendent Rusk of the Platts group, near Sumpter, states that the working force, both underground and on the surface, is to be increased.——Deep work at the Indiana mine, near Baker City, has been progressing since the management was authorized to put in a sinking plant.——On the Golden Gate mines at the head of Desolation creek, Greenhorn district, a 40-foot tunnel has been driven.

Douglas County.

Manager W. B. Stewart of the Continental M. Co. at Nugget has shipped a third carload of ore to the Tacoma smelter. The winze being sunk from the 500-foot level is down 75 feet. A 50-ton concentrating plant is to be put up.

Grant County.

According to the statement of Manager J. Thomsen work on the Olive lake power plant of the Red Boy mine, near Granite, will begin soon. At a recent meeting of the Red Boy Co. the water rights, ditches and flumes owned by it were sold to a new company for $50,000, to be paid in electric power.

Manager O. C. Wright has resumed work on the Sheridan, near Granite.

Josephine County.

Manager C. R. Ray of the Condor Co. intends to resume drilling with the Keystone prospecting drill on the McConough ranch, near Gold Hill, on which he took a bond last year.——Work on the High Line ditch, which is being built at Gold Hill, proceeds on an increasing scale.

F. W. Blaisdell is preparing to finish his ditch from Reuben creek to his placer mines on McNail flat, in the Grave creek district, near Grant's Pass. The ditch will be about 8 miles in length when completed, and will have one inverted siphon.——A California company has a drill prospecting the Wimer mine, at Waldo.——T. W. M. Draper has a drilling machine at work prospecting in the Waldo section, and has recently located 2000 acres of placer ground.

Lane County.

Operations at the Lucky Boy mine at Blue River, owned by L. Zimmerman of Portland, have been steady for some time. The 40-stamp mill is in commission, with an abundance of water and power for milling purposes.——The Treasure mill is expected to be finished in September

Wallowa County.

High-grade copper and silver ores are said to have been discovered in the mountain ranges south of Lostine. This district comprises an area 35 miles long and 12 miles wide, between Eagle creek and Wallowa river. Lostine may be reached by the O. R. & N. railroad to Elgin and then 40 miles by stage, or from Lewiston, Idaho, by wagon road, 90 miles in length. The first locations in the district were made by J. Dunn of Joseph, Or. The Great Northern Gold & Copper M. & M. Co. is developing thirteen claims under the management of E. T. Sluer. He has men rebuilding the trail between the Iron Dike camp and Windy Gap, in the Calumet camp, where the property of the Great Northern Co. is located.

SOUTH DAKOTA.

Lawrence County.

It is reported that the Homestake Co. is to build an immense plant at Deadwood to treat the slimes from the Lead and the Central plants. Filter presses designed by C. W. Merrill will be part of the equipment.——The Lucky Star M. Co. has started work on its properties between the Lucky Strike and the Clover Leaf mines. J. G. Reid of Minneapolis is president and C. A. Allen of Deadwood treasurer.

Pennington County.

(Special Correspondence).—At a meeting of the directors of the Clara Belle M. Co., held in Cleveland, Ohio, July 31, the following officers were elected: Frank Hebert president, N. P. Bowler vice-president, A. R. Teachout treasurer, L. Hebert secretary, Walter Lister assistant secretary. The company is now improving the property, erecting a first-class stamp mill and saw mill, building a tramway, a large boarding house and other buildings. About twenty-five men are at work and more will be put on soon. The property consists of 180 acres, 1 mile from Oreville, near Hill City, on the Burlington Railroad. The work is an important one and will help to develop this country, which is rich in minerals.

Oreville, Aug. 7.

UTAH.

Grand County.

In the La Sal mountains, near Basin, considerable work has been done since July 1. Superintendent M. I. Fowler has opened up a new vein on the Tornado on Gold Hill. J. Beasley of Provo is said to have struck gold and copper ore on the Dirigo La Sal Co.'s property in Bea er basin.——W. R. Wheat of Basin, manager Grouse Mountain Co., expects to start work on a 100-ton cyanide plant next year. Work is to be continued on the lower tunnel, now in 350 feet.

Juab County

J. Aylward has finished building a 1500-foot cable for the Bullion-Beck mine at Eureka.

The ore shipments in carloads from Tintic for the week ending August 4 were: Gemini 6, Bullion-Beck 5, Centennial-Eureka 56, Yankee Con. 3, Eagle & Blue Bell 10, South Swansea 5, Uncle Sam 3, Victoria 4, Ajax 3, Carisa 1, Mammoth 11, Lower Mammoth 1, Grand Central 3; total 111.

Manager J. C. Sullivan, of the Raymond mine at Eureka, is reopening the property by work in the south drift on the 1500-foot level.

Piute County.

Work has been started on the new 200-ton stamp mill of the Sevier Con. Co. at Gold Mountain, near Kimberly.

Salt Lake County.

The capacity of the Yampa smelter, at Bingham, is to be increased 100 tons by the construction of another reverberatory furnace and four roasters. The plant will then consist of two blast furnaces, two reverberatories and six roasters and it will be able to handle 500 to 600 tons daily.

Summit County.

The Wildflower claims, near Park City, are to be worked by a company, of which W. H. Whitehill of Park City is president.——At the Daly-Judge mine, at Park City, little is being done beyond prospecting.

Tooele County.

Settling tanks and a canvas plant are being put in the Stockton mine at Stockton. A new vein, said to be 30 feet wide, has been opened up on the 850-foot level.

Utah County.

The mill test having been completed, it is stated the Utah Ozokerite Co. mine at Colton will resume operations and a mill of fifty tons' daily capacity will be built.

WASHINGTON.

There was a decrease of $136,000 in the production of gold in the State of Washington last year, according to the estimate of F. A. Wing, assayer in charge of the Government assay office in Seattle. The same authority gives the decrease in silver production as exceeding $232,000. On the other hand there was a gain in the output of copper and lead. The gold production in 1904 was 15,009.977 fine ounces, value $310,283.76; silver (coining value) fine ounces, 1904, 125,312.18, value $162,019.78; copper 199,670 pounds, value $25,475.45; lead fine pounds, 378,588, value $16,312.06. Total values, 1904, $514,091.05.

Ferry County.

The Belcher M. Co. has purchased an 8-drill electric plant for the Belcher mine, near Republic, and a similar outfit for the Hawkeye mine, the latter being owned by the Winnipeg M. Co. They also purchased a 35-ton direct connected locomotive, suitable for traction on heavy grades, and 100 tons of relaying rails for the Belcher Mountain railway, of which E. R. Fraser is president. An electric lighting plant was purchased for use at the mines, intended at the start for sixty lights. A gasoline engine will be used to drive the dynamo for generation of electric power, to be subsequently reinforced by water power.

Douglas County.

The Waterville Coal Co. has commenced work on a coal prospect across the Columbia river from Wenatchee. W. Milburn is manager.

Stevens County.

The new ore bunkers for the Copper King ore at Chewelah are completed and the traction service is making regular trips, hauling ore from the mine. The ore is dumped from the traction cars through a shoot into the railroad cars, obviating handling the ore by hand. J. D. Blevins is superintendent.——President H. H. Baker, of the Nellie S mine, has let a contract to G. Abbott and L. Barnes to sink 100 feet on this property. The contract commences at the 160-foot level and when completed will give them a depth of 260 feet.

Okanogan County.

J. Boyd, manager of the Palmer Mountain Tunnel & Power Co. at Loomis, reports that a 750 H. P. water and electric power plant is to be put in and operated under a 365-foot head, on Touts Coulee creek. Electric power drills for the mines are to be put in. There is talk of a 300-ton stamp and cyaniding mill to be built within 1500 feet of the mouth of the tunnel. C. S. Reitze will have charge of the electrical construction and equipment.

WYOMING.

Carbon County.

F. E. Brown has started work at the Batchelder mine, near Dillon, which has been closed down for five months. ——E. M. Sanders has started work on the Wall Rock, adjoining the Pluto mine, at Dillon.

FOREIGN.

AUSTRALIA.

New South Wales.

The value of the minerals exported during the half year ending June 30 from New South Wales was as follows: Silver, £23,746; silver-lead, £1,179,981; copper, £234,148; tin, £138,387; coal, £667,615; total, £2,243,876. The amount for the corresponding period of last year was £2,038,772.

Western Australia.

In the State of West Australia the Government gives assistance to small prospectors and small mine owners who are without means and have good prospects. They can have their ore crushed cheaply, and assistance is given in supplying them water from the Gold Fields Supply Scheme. The principal way in which the State helps the miners is by crushing their ore in the State batteries, as the private facilities on the fields are not always adequate for the ore obtained and at other times are not available. By this means many of the smaller mines have been kept going and those that were closed have, in many cases, been reopened. Crushing is done only for small mines. Electricity is used on the fields, where the larger mines are lit by it and have their own motors. There is always a market for the gold at the Government mint in every State.

CANADA.

BRITISH COLUMBIA.

Atlin District.

A new placer gold strike has been made on the Nitsultin river, which flows into Teslin lake in the Atlin country, and there has been a rush to the diggings both from Atlin and Whitehorse.——D. McG. Stewart, manager of the Northern M. Co., has started a steam shovel on Spruce creek, Atlin.

Boundary District.

Boundary ore shipments for week ending Aug. 5 were Granby mines to Granby smelter, 13,325 tons; Mother Lode to British Columbia Copper Co. smelter, 3163 tons; Emma to Nelson smelter, 396 tons; Oro Denoro to Granby s nelter, 68 tons; Providence to Trail smelter, 30 tons. Total for week, 16,985 tons. Total for year, 540,022 tons. Boundary smelters this week treated: Granby smelter, 13,540 tons; British Columbia Copper Co. smelter, 3590 tons. Total for week, 17,130 tons. Total for year, 552,-872 tons.

W. A. Robertson of Chicago, acting for the Barbara Syndicate, has consolidated the Freemont, Strathmore and Barbara mines. The Strathmore and Barbara are developed properties and ready to ship.

Rossland District.

The shipments have passed the 200,000-ton mark for the year and the outlook is that they will reach a larger tonnage than last year, when the total was 340,000 tons. The shipments for the week ending Aug. 5 were: Le Roi, 1950 tons; Le Roi (milled), 210; Center Star, 2100; Le Roi No. 2, 90; Le Roi No. 2 (milled), 600; Jumbo, 400; Lily May, 30; Inland Empire, 30. Total for week, 6750, and for the year, 201,953 tons.

Slocan District.

The No. 1 mine at Ainsworth has shipped six cars of ore to the smelter and will be a continuous shipper during the summer. H. Giegerich of Kaslo is manager.—— The mill at the Jackson mine, 5 miles from Whitewater, is doing splendid work on the zinc ores of the mine. About 500 tons of zinc ore is in the concentrates pile. Some of this requires separation, but another separate pile runs above 50% zinc. —— J. Cronin will start up the Eureka group, across from the Slocan Star, near Sandon.

West Kootenay District.

An 8-foot ledge of very rich silver-lead ore has been discovered on the Sirdar, one of the claims of the Mammoth group on Goat mountain, near Camborne. E. Baillie is manager. —— A new company called the Camborne M. Co. was formed at Calumet, Mich., on July 21, to take over the affairs of the Northwestern Development Syndicate, Ltd., and the Gold Finch M. Co., Ltd., at Camborne. Last summer the mine buildings and tram of the Gold Finch were burned. —— The McMinnville group on the lower slope of Lexington mountain, near the Eva mine, in the Lardeau district, will be worked by M. U. Gortner, M. Morgan, F. Morgan, C. A. Nelson and G. B. Row. It is reported that a new mill is to be put in.

MEXICO.

Chihuahua.

(Special Correspondence).—There has been a drilling contest in the Sierra de Almaloya between the Cigarrero mine, using the Box and Adams electric drills, with gasoline engine, and the San Enrique mine, adjoining the Cigarrero on the east, using a gas producer, air compressor and the small "Rock Terrier" drills. Both are driving tunnels in the same limestone formation. The management of both companies seem satisfied with the progress made, and are about to put in 300 H. P. plants to run more drills, hoists, etc. For some time neither have shipped ore, but with the completion of the electric tramway for the Cigarrero and the aerial cable tramway for the San Enrique, there will be another interesting contest as to the amount of ore that can be shipped per month.

Almaloya, Aug. 1.

The San Cristobal shaft at Parral has been retimbered and a new steam hoist put in, and development work will be pushed by Superintendent Gerhardt.——A 50 H. P. electric hoist has been put on the Virginia shaft of the Palmilla mine at Parral, and a like hoist will be put on the San Francisco shaft.——The new stack of the Encinillas Mines, Ltd., at Santa Rosalia is nearly finished.——The shaft on the Palmira, belonging to Weisel & Kock, is down 350 feet. A new gallows frame and machinery have been put in.

Durango.

J. P. Julia of New York has bought the Sederita mine at Mapimi. The mine is a copper proposition and is connected by road with the railroad station at Desubridora. He has commenced development work.

Jalisco.

The mill and cyanide plant of the San Felipe M. Co. at Hostotipaquillo have been started. N. Z. Seitz is president and general manager.——It is reported that the work on the cinnabar deposits near Moral, in the Mascota district, and the silver-gold mines in the Navidad camp of that district will be pushed by the El Moral M. Co., in which T. W. Lawson and F. W. Page are said to be interested. A reduction plant and furnace are to be put up. These properties were formerly worked by the United Mexican M. & S. Co.

Sonora

The Monte Visto G. & S. M. Co. have taken over the Monte Visto mine, 15 miles east of Cos.——It is reported that O. L. Neer, until recently general manager of the Transvaal Copper Co. at Cumpas, Sonora, has purchased, for Cincinnati capitalists, the York mines, near Moctezuma. Extensive development is the plan of the new owners.

PHILIPPINE ISLANDS.

Copper has been mined and smelted in a crude way in the Philippines since the eighteenth century, according to H. J. Stevens. In a native reduction plant the ore after being hand mined is cobbed to medium size, then broken to smal lumps on anvils, after which it is fine crushed in rolls of iron or stone. The ore is then smelted in crude furnaces. There are no figures of output available. There are copper and gold mines at Mancayan and Suyoc, province of Lepanto, Island of Luzon. There are also deposits of copper ore in the islands of Benguet, Negros, Panay and Mindanao.

Books Received.

The progressive engineer is hunting for short cuts that facilitate accomplishing more work in shorter time, yet withal and above all of indisputable accuracy. This seems to have been accomplished for hydraulic engineers in "Hydraulic Tables," by G. S. Williams and Allen Hazen. With great detail they show the loss of head due to the friction of water flowing in pipes, aqueducts, sewers, etc., and the discharge over weirs. According to the introduction they show the flow of water in pipes and other passages, as computed by the Hazen-Williams hydraulic slide rule, based upon the formula $v = cr^{0.63}s^{0.54}0.001 - ^{0.04}$. The most commonly used formula for determining the velocity of flow of water in pipes and channels is the Chezy formula, namely, $v = c\sqrt{sr}$, where v is the velocity in feet per second, s is the hydraulic slope, and r the hydraulic radius in feet; c is a factor the value of which is an approximation to a constant, but depends upon the roughness of the pipe and upon the hydraulic radius and slope. The variations in the value of c are considerable, and make the general use of the formula difficult. Kutter's formula was devised to compute the value of c in the Chezy formula. The tables give a series of values of c according to the age of the pipe. They are published by John Wiley & Sons, New York City, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $1.50.

As an extract from the "Mineral Resources of the United States for 1904," the United States Geological Survey has issued the "Production of Salt for 1904." This was reported to be 22,030,002 barrels (of 280 pounds), valued at $6,021,222, as compared with 18,968,-089 barrels, valued at $5,286,988, in 1903. The chief salt producing States are New York and Michigan, and the combi ed output from these two States amounts to about two-thirds of the total production of the United States. The five leading salt producing States during 1904 were: New York, 8,600,656 barrels (39.04%); Michigan, 5,425,904 barrels (24.63%); Ohio, 2,455,829 barrels (11.15%); Kansas, 2,161,819 barrels (9.81%); Louisiana, 1,095,850 barrels (4.97%).

Commercial Paragraphs.

THE United Iron Works have received a contract from J. G. White of New York City to furnish a suction dredge 22x44 feet, run by gasoline engine, to be used in removing silt preparatory to building a large dam near Yuma, Ariz. The dredge is to be working within sixty days.

THE Rapid Economy Stamp Mill Co. of San Francisco, Cal., report that they are putting in a number of their stamps upon the Fern Leaf mine in Trinity county, Cal., and that the Chuckawalla M. Co. of Los Angeles, Cal., has contracted with them for the erection of a Richards' Rapid Economy stamp mill on their property.

THE Sullivan Machinery Co. is adding to its manufacturing plant at Claremont, N. H., to keep pace with the rapid growth of business in mining and quarrying machinery. The improvements comprise six new buildings, practically doubling the present plant. The company has recently shipped to Colon, Canal Zone, Panama, twenty-five rock drills, size UH-11 (3½-inch), fitted with the new Sullivan tappet valves, for the Isthmian Canal Commission.

Obituary.

GUSTAF H. STOIBER, a prominent Colorado mining man, died at Silverton, Colo., on the 3d inst.

Personal.

G. G. HALL has charge Conger mine, at Bingham, Utah.

WM. TRELOAR is manager Hobart Ore Co., in Sparta district, Minn.

D. F. STROBECK is manager Pacific Bullion Co. at Ainsworth, B. C.

J. D. SPARGO is superintendent West Gold Road mine, Acme, Arizona.

R. H. WARD has returned to San Francisco, Cal., from an Eastern visit.

J. V. N. DORR has returned to Terry, South Dakota, from a visit to New York.

T. H. SCOTT is directing work for the Great Western M. Co. near Burke, Idaho.

RAY POOL has been appointed superintendent Tehuana M. Co., El Oro, Mexico, Mex.

G. W. MAYNARD is consulting engineer Guanacevi Tunnel Co. at Guanacevi, Durango, Mex.

G. P. ROUX has been appointed superintendent San Felipe mines at Hostotipaquillo, Jalisco, Mex.

S. J. GORMLEY has been made superintendent Bingham Copper Co.'s smelter at West Jordan, Utah.

W. W. BYRNE of Salt Lake City, Utah, is making a trip through Washington, Oregon and California.

H. G. MONETON has taken the position of mining engineer for the Vesuvius G. M. Co. of Bohemia, Or.

W. P. SWART of Fulton Iron Works has returned from Tonopah and Goldfield, Nev., to San Francisco, Cal.

MRS. M. M. GARWOOD, editor "Progressive West," is now secretary Reno, Nevada, Chamber of Commerce.

R. H. STRICKLAND of Salt Lake City, Utah, has joined the engineering staff of the American S. & R. Co.

MARK B. KERR, having completed his work of mine examination in Inyo county, Cal., is now at Silver Peak, Nev.

A. DEL MAR of San Francisco has gone to San Bernardino county, Cal., to investigate mining properties.

H. W. WALLACE has been made manager Sombreretillo M. Co. at Saria, Sonora, Mexico, succeeding C. F. Tolman.

RICHARD ROELOFS has been appointed superintendent Cresson mine of the Bull Hill M. & D. Co., Cripple Creek, Colo.

J. A. FARWELL, vice-president J. Geo. Leyner Engineering Co., has returned from San Francisco, Cal., to Denver, Colo.

C. M. FUELLER, Denver, Colo., is making examination of the Redeemer M. Co. property, 250 miles east of Winnipeg, Canada.

WM. A. HEWITT, president Compressed Air Machinery Co., has returned to San Francisco, California, from Tonopah, Nevada.

BYRON E. JANES has been selected as head of the department of mining and metallurgy of the University of Idaho at Moscow.

J. D. KENDALL of London, England, consulting engineer of the Slough Creek Gravel Gold Co., is at Slough Creek, Cariboo, B. C.

WM. LOVELAND, manager moving machinery depart ment Allis-Chalmers Co., has returned to Chicago from a business tour through the West.

C. F. TOLMAN JR. has been appointed professor o geology in the University of Arizona at Tucson, succeeding W. P. Blake, resigned.

H. V. CROLL has opened offices in the Dooly block' Salt Lake City, Utah, as representative of the Wellman-Seaver-Morgan Co. of Cleveland, Ohio.

J. E. HYSLOP, manager of the San Francisco del Oro mines, near Parral, Chihuahua, Mexico, has left for England. W. S. Harrison has charge during his absence.

F. G. WILLIS of the firm of Hills & Willis, mining engineers, Cripple Creek, Colo., is examining mines in Boise county, Idaho. His address till Sept. 10 will be Pioneerville, Idaho.

J. D. STEWART of Gold Run, Cal., is manager and superintendent Klamath River M. Co., with mines at O'Neals creek, Calaveras county, and Klamath river, Humboldt county, Cal.

B. N. NIEDING has resigned as superintendent Tip Top Copper Co. at Helvetia, Ariz., to become superintendent Niblack copper mines, near Ketchikan, Prince of Wales Island, Alaska.

A. H. CARPENTER has resigned as manager smelter at Takilma, Or., and is in Denver, Colo. George Cresar and R. S. Stetson are managing and W. S. Keith superintending the smelter operation.

JOHN INGERSOLL has resigned his position as superintendent of the Hidden Fortune mill, near Deadwood, South Dakota, to return to his old position of superintendent of the Dakota mill, near Deadwood.

W. LINDGREN, geologist, is in San Francisco, Cal., from Washington, D. C. He has lately been given charge of the gold and silver statisties of the United States for the Geological Survey, and is now investigating the work of the special agents for California, Nevada, Oregon and Washington. His headquarters will be San Francisco for several weeks.

Trade Treatises.

The special jubilee number of the "Valve World" portrays fifty years of progress of the Crane Co. of Chicago, Ill.

The Colorado Iron Works of Denver, Colo., has issued as catalogue No. 12 "Some Details as to Smelting Practice and Equipments." This is the fifth edition of what has proved to be a practical treatise on blast furnace smelting.

Latest Market Reports.

SAN FRANCISCO, August 11, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27⅛d (standard ounce, 925 fine); New York, bar silver, 59⅜c, refined (1000 fine); San Francisco, 59⅜c; Mexican dollars, 46c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.50; Lake, 1 to 3 casks, $15.37½@15.62½; Electrolytic, 1 to 3 casks, $15.50; Casting, 1 to 3 casks, $15.00 @ 15.25. San Francisco: $16.00. Mill copper plates, $17.00; bars, 18@24c. London: £69 spot per ton.

An electrical engineering paper of current issue calls attention to the industrial risk the United States takes in shipping abroad such large quantities of copper as have been sent to Europe and the Far East the past two years. The demand of home industries are nearly sufficient to absorb the domestic output of the metal, and the shipment of such great amounts to foreign countries has about absorbed all the reserve stock on hand. The fact is pointed out that copper, aluminum and iron are the only metals practically available for electrical uses, and of these copper is the most important. Iron and aluminum can be employed as conductors of electricity, but the wire winding of dynamos, etc., is almost wholly done with copper wire, and this is a use which requires an enormous quantity of the metal. Electric light and railway uses consume annually a very large part of the output of this country, beside which another large amount is absorbed by the brass founding industry. The development of new mines does not nearly keep pace with the rapid exhausting of the producing mines. In view of these considerations the copper outlook for the future is promising.

LEAD.—New York, $4.75; Salt Lake City, $3.50; St. Louis, $4.52½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £14 ℔ long ton.

SPELTER.—New York, $5.70; St. Louis, $5.18; London, £24 ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $32.25@32.75; San Francisco, ton lots, 33½c; 500 lbs., 34c; 200 lbs., 34½c; less, 35½c; bar tin, ℔ lb., 35@37½c. London, £148 10s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 18.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.85; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$21.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 12½c; Hallett's, 13c; San Francisco, 1000-lb. lots, 11c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12⅝c ℔ set; 14 oz. stearic, 40s, 11⅛; 12 oz. stearic, 40s, 10⅛c; 10 oz. stearic, 40s, 9⅛c. 100-case lots and over, ⅛c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ¼c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¾c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

OILS.—Linseed, boiled, bbl., 64c; cs., 69c; raw, bbl., 62c; cs., 67c; Lucol oil, boiled, bbl., 56c: cs., 61c; raw-bbl., 54c; cs., 59c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11⅞c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.25.

URANIUM.—Oxide, ℔ lb., $3.50.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

LUBRICATOR.—No. 796,125. Aug. 1, 1905. H. P. Josewski, San Francisco, Cal. The object of this invention is to provide a device by which a stated amount of lubricant will be supplied to the bearing or part and without danger to the operator by reason of getting into the way of running belts or moving machinery. The device comprises a container, including a cylinder and upper and lower heads, the lower head having an aperture through it with walls diverging toward the outer face of the head. A plate fits directly against the lower head, the face presented toward the outer face of the head, and provided with an opening whose walls converge oppositely to the corresponding walls of the opening in the head whereby a chamber of double conical shape is formed between the meeting faces of the head and plate. There are other parts of construction designed and arranged to bring about the desired result.

LINE GRIP HOLDER.—No. 796,143. Aug. 1, 1905. Alexander Nord, San Francisco, Cal. This invention relates to a device for holding clothes lines and generally lines of any kind which it is desired to secure so as to be easily drawn taut or readily released. It consists of a body portion having a projection from one side, and an arm projecting rigidly therefrom, a means for attaching the device at one end and guides for the line in the opposite end. A second portion is pivoted to the outer end of the projection of the first portion having an arm projecting from one side, and a lever arm from the opposite side, said arms and lever arm serving to grip turns of the line which are made between the movable and fixed portions.

DRILL HOLE ENLARGING DEVICE.—No. 796,165. Aug. 1, 1905. T. M. Topp, Raymond, Cal. The object of this invention is to provide a means by which after drill holes have been made in rock or other material the bottom of such holes may be enlarged and a chamber formed for the reception of the explosive with which the drill hole is to be subsequently charged. It may also be employed for enlarging similar holes for other purposes. The device may be used in connection with hand or machine drills and turned in the usual manner for drilling ordinary holes. All the parts are loosely fitted together They may be easily assembled or dismounted without the use of screws or bolts or implements of any kind.

FRUIT PACKING MACHINE.—No. 796,156. Aug. 1, 1905. S. H. Shelley, San Jose, Cal. The object of this invention is to do away with the expense and time of manually "facing" the box and by a simple method mechanically packing the prunes into the box in cubes or bricks of uniform weight and size similar to cartons without in any way injuring the fruit or detracting from the appearance of the box when opened. It consists in an apparatus for packing prunes, a cellular open-ended mold adapted to be inserted into a box and having a portion extending above the box, means interposed between the box and the mold, and telescoping with the box and mold to p e-vent the escape of material therebetween, said interposed means carried by the mold, means for compressing the contents of the cells of the mold, and means for withdrawing the mold during the compression period.

Whole No. 2350.— VOLUME XCI. Number 8. SAN FRANCISCO, CAL., SATURDAY, AUGUST 19, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

California's New Inland Sea.

For several months past the Colorado river has been pouring a vast flood of fresh water into the depression in San Diego county, Cal., known as the Salton Basin. This basin or sink is below the level of the sea, being about 260 feet below datum at the lowest place — the salt marsh near Salton station. There are in the world only half a dozen places where the surface is below the level of the sea. These are the Salton Basin in San Diego county and Death Valley in Inyo county, Cal., the Valley of the Jordan in Palestine, where the noted Dead Sea is nearly 1300 feet below sea level; two small areas in the Sahara desert of Northern Africa, and the largest, by far, of all, and exceeding them in the aggregate area — the valley of the Caspian sea in Western Asia — which is 86 feet lower than the Black sea.

At one time, in recent geological age, the Salton Basin in California was connected directly with the Gulf of California. The Colorado river, flowing with a sinuous but generally southerly course, emptied into this broad, shallow sea. Its great volume of sediment, upon reaching deeper water, settled to the bottom, gradually filling up the channel, and spreading out over a large area. In time a spit was built at the west side of the stream, which gradually extended out into the Gulf of California, eventually forming a complete barrier and cutting the Salton Basin off from the Gulf. This required many years in its accomplishment.

In periods of low water the river fell below the level of the sand spit and in time of flood cut crevasses through it, newer additions being made to the natural embankment until it became a broad levee, completely shutting off the basin from both the river and the gulf, and only at times of unusually high water did the river breach its banks and overflow into the basin. This has occurred repeatedly in past years, though at long intervals, the last time being in 1891–92, when the river flowed through a cut in the bank made by high water, and the water reached the salt works at Salton; but, the river receding, the supply of fresh water was cut off and the newly formed lake rapidly disappeared by evaporation, and no great damage was done.

In the spring of 1905, however, an irrigation canal was cut for the purpose of irrigating lands about Imperial, a town which had grown up in the heart of this desert wilderness, where the soil is wonderfully fertile when it can be properly irrigated.

In this work a breach was made through the levee, but the mistake was made of not providing the necessary head gates. Soon after connection was made between the canal and the river, the summer flood of the river occurred, due to the melting of the snows in the Rocky mountains where the Colorado river takes its rise, and the unusually heavy rainfall increased the volume of the river until an irresistible flood poured into the basin. Many square miles of the basin are now under water, and if it is not checked, without doubt the basin will fill in time, to the level of the inflowing river, when a spit will again be built by nature across the crevasse and the stream continue on its way to the Gulf as before.

The Monuments Control.

The United States Land Department has recently rendered a decision to the effect that in the event of any error in the description of mineral claim surveys or of the line tying the claim survey to a government land survey corner, the monuments must control, which is quite at variance with the position taken by that department nearly two years ago, when there was much controversy over this subject. On April 28, 1904, Congress amended Section 2327 of the Statutes in such a manner that this principle is clearly enunciated, and the recent decision of the United States General Land Office referred to is in direct line with the amendment, and was no doubt influenced by it to a great extent, so that hereafter there need be no apprehension when an error is detected in the survey of a mineral claim for patent, as, regardless of all errors, the monuments must control. This was the position taken by the MINING AND SCIENTIFIC PRESS in the latter part of 1903, when the Land Office at Washington caused consternation throughout the mining States of the West by announcing that the surveys must stand, and that the "calls" of the United States deputy mineral surveyors must take precedence over monuments and everything else. The decision was manifestly so unjust, and so contrary to the purpose and intent of the law, that there was no hesitancy in declaring even at that time that the monuments must control, and any case wherein this question was the issue the United States Supreme Court would decide in favor of the claim owner and against the decision of the Land Office. So earnestly did the miners of the West take up and combat the proposition that Congress quickly recognized the necessity of settling the point for all time, and amended the section bearing upon this matter, as above stated, and the Land Office now falls in line and announces a decision in exact conformity with the amended law.

The Premium System.

It is always the desire of the mine superintendent or manager to have the work under his direction done at as low a cost as consistent with a proper regard for the men, and the conditions under which the labor is performed. Experienced managers know that it is not economy to require men to work in poorly ventilated workings, nor to demand that the men work in a constant shower of water, where it can be avoided. There are places where these difficulties are met and are most difficult to overcome, and the wise manager makes it his business to see that the unpleasant and disadvantageous situations in which the men labor are made as comfortable as circumstances will admit. The additional work the men are enabled to perform by reason of the improved condition more than pays for the expense of making the necessary change. Men will not, and cannot, work in a vitiated atmosphere, nor in a heavy downpour of water. Good ventilating plants improve the one condition, and temporary protection of some sort, in the way of an improvised roof of corrugated iron, shingles, or heavy prepared paper, alleviate the other. One of the most difficult tasks falling to the lot of the mine superintendent is to get a proper return in the form of labor performed from the men employed in exchange for the wages paid. One of the first things to be considered in this regard is the fact that good wages attract good men, while if wages are low and working conditions bad the best men will learn of it and stay away from a mine or camp where these unfavorable conditions obtain.

After good pay, the next most important matter is the proper judgment of what constitutes a day's labor. How often the miner who has been sent to the office with his time check sneeringly complains that "the shift boss or foreman doesn't know when a man is doing an honest day's work." In some instances this remark may have some foundation of truth in it, but, even so, it is quite as probable that the discharged miner was not only not doing what a competent judge would consider a proper day's work, but that he was performing far less than he could, and that his leisurely or careless way of doing things was likely to affect the other men on the shift adversely to the interest of the employer. When the laggard is permitted to set the pace, things soon go badly, indeed.

As a stimulus to greater endeavor, the premium system is sometimes introduced in the workshop and in the mine, and in many instances this works satisfactorily, but here experienced judgment is required in setting the minimum task. If this be too low the result can more easily be imagined than described. If the limitation be too high the men will be unable to reach it, and knowing it, will fail to make the desired effort. One good way to adjust this difficulty, if the conditions are unfamiliar to the manager, who may be new to the country, is to let a series of contracts to determine what the men are capable of performing under favorable wage rates. Then, basing the judgment on the results obtained, the premium system may be safely and satisfactorily introduced.

FOR some time past the copper situation has been set forth in these columns, and the conditions seemed to warrant a steady market and higher prices. The price of the metal has slowly risen in fractional figures until 16-cent copper is again all but assured. Some metal is reported to have been sold at 16 cents and the latest reports state that fine Lake and electrolytic copper can scarcely be obtained under that price. Should the present favorable conditions continue, there is no doubt that the market price of copper will slowly advance, and it seems not overhazardous to now predict the probability of 17-cent copper.

WITHIN the week Humboldt county, Nev., has attracted unusual attention by bringing forth an active mud volcano. The rent is several miles northerly from Lovelocks, in the Black Rock Desert region. As yet there is little apprehension of serious damage. The former existence of mud springs similar to the one now active is evidenced at many points in the Great Basin region. They are of the non-explosive type and usually altogether local in effect.

Railroad Lands in Nevada.

Near Olinghouse, in Washoe county, Nev., much consternation has recently been created by the claims of the Southern Pacific Railroad to land containing mining locations in Olinghouse canyon, White Horse district. These claims are on the odd-numbered sections which fall within the zone of lands granted to the Central Pacific Railroad by the government. The law makes express provisions as to what class of lands shall be deeded to the railroad. All lands known to be more valuable for mineral than for other purposes, at the time the final lists filed by the railroad are accepted by the land department, are reserved from the railroad grant, except those containing coal and iron.

Wherever conflicts of this character arise between the mineral locator and the railroad, it becomes a question of facts, in which that of the greatest importance is, when was the land first recognized as, and known to be mineral, as related to the date of the railroad patent? A discovery of mineral, after patent has issued (and possibly after the final listing of lands by the railroad, has been accepted by the land office), by the miner, will not avail him as against the railroad. There seems promise of a hard-fought legal battle over the title to these lands. If the miners can establish the fact that the lands in question were known to be mineral prior to acceptance of the railroad company's list of lands for which they desired patent, then the miners will undoubtedly win their case, for upon this question the entire proposition rests.

When the railroad company decides to take out a patent on certain of the lands within the grant zone, they make a list of such sections, or parts of sections, as they wish to patent, and file the same in the general land office. This is very much in the nature of the application of a private citizen for patent to a mining or agricultural claim. The land office then reviews the land and attempts to determine whether the land embraced in the application of the railroad comes within the definition of mineral or not. The lists of those lands determined not to be mineral are accepted, and thereafter the land is closed to occupation by any except the railroad. It would seem that in a contention of this kind there should be no difficulty in arriving at the facts in the case.

The Best Policy.

For generations past we have been taught the familiar old saying, "honesty is the best policy." For years this old saying carried much weight and was generally accepted as an axiom, but in the light of modern business standards and that which goes to make success, is honesty still the best policy? In considering this sentiment we must first inquire what is expected to be attained by honesty. If it be a reputation for integrity, high-minded purpose and earnest effort to live up to the Golden Rule, then honesty is not only an essential, but is practiced because it is right. To be "honest" merely because it is "policy" to be so is a species of honesty that will not bear much pressure. When applied to the flotation of certain mining and smelting propositions in these modern days, it is clearly evident that "honesty is not the best policy," for in ninety-nine cases out of one hundred, if the exact truth be told, the proposition would present so little attractiveness that the promoter would find it difficult to give his stock away. The investing public wants something that looks alluring — they want an investment which will place them in an easy financial position on what is apparently a comparatively small risk. Should the mine promoter point out the difficulties in the way of development and operation of the enterprise he is endeavoring to float, and enlarge upon the uncertainties of undeveloped mines, or the unanticipated fluctuations of the market, he would find few purchasers for his wares. Knowing this, he pursues the directly opposite tack, and puts the best of everything forward—points out the great successes of famous mines, and without hesitation draws an analogy, and easily shows that his property possesses every element found in the successful one, with a slight difference in favor of his proposition, and in his enthusiasm forgets the old adage and schools himself to believe otherwise.

CONCENTRATES.

A 36-INCH CIRCULAR SAW may be safely run at 1000 revolutions per minute. It is permissible to run saws at a higher speed than flywheels of the same diameter.

A GREAT deal has been written on the genesis of the diamond, but up to the present time none of the theories advanced satisfactorily account for its occurrence.

IF pending patent proceedings the owner of an unpatented mining claim fails to perform the necessary assessment work, the claim becomes subject to relocation.

EARTH and fine rock, when excavated and placed in a bank, alway settle and shrink. The amount of shrinkage is variable, depending on the class of material.

THE reactions given by bismuth when heated on charcoal are very similar to those of lead. Bismuth will form a brilliant orange-red coloring on the coal and lead a yellow color.

THE pressure on the pipe line leading to Virginia City, Nev., is at one point 1700 feet. The water used in unwatering the Comstock mines is used under a pressure of over 2700 feet.

TO ELEVATE pulp or tailings in mills, belts, endless bucket lines, platform elevators, sand wheels, pumps of several types, including the spiral, and the hydraulic jet are employed. Each of these devices have a greater or less application to varied conditions.

THE presence of magnesium may be detected in a mineral by making an acid solution strongly alkaline with ammonia, when the addition of sodium phosphate will precipitate any magnesium present, forming white crystalline precipitate of ammonium-magnesium phosphate.

BELT CONVEYORS can be used to good advantage in many situations about a mine. They can be applied to the handling of ore in surface cuts, in underground stopes, in the mill and in many other places where ore or waste must be moved from one point to another at small cost.

THE deepest anthracite coal mine in the United States is at Brookside Colliery, near Tremont, Pa. It is down 1850 feet. Although the head frame, winding plant and other surface equipment of coal mines is usually more elaborate than that at the shaft of metal mines, the latter average a greater depth than those of the coal mines.

THE tanks of the cyanide or chlorination plant should not be placed on the ground, nor on beams laid upon the ground, but upon aframework of timbers which is so constructed that a workman may get under the tank to make any necessary repairs or changes. The foundations for tanks must be firmly built so that there shall be no subsidence.

THE proper function of a factor for safety is not to cover up mistakes in engineering, but to make the necessary allowance for defects in materials employed in construction. It does not necessarily assume that the material and workmanship will be poor, but it provides a margin for safety in the event that such should prove to be the case.

TIN smelted in reverberatory furnaces by the Mount Bischoff Company of Tasmania is refined by skimming off the slag after partial cooling, and forcing pieces of green wood beneath the surface of the still molten metal, the steam formed releasing the dross, which is skimmed off. The refined metal assays 99.8% tin, and is shipped to England in ingots of 75 pounds weight.

A "JUMPER," in mining parlance, is the term used in the English colonies to indicate a drill of some length, which is used to drill holes without the use of a hammer, the bar being raised by hand and allowed to drop, the cutting being done by the force developed by the weight of the falling drill. The jumper is known in the United States as the "churn drill."

IT is stated that the dissolution of gold in cyanide solutions is accelerated by bright sunlight. This is said to apply to both potassium thiocyanate and to potassium aurocyanide. This acceleration in the dissolution of the gold is supposed to be due to the liberation of more nascent cyanogen in proportion to the additional oxygen absorbed, with a consequent increased formation of aurous cyanide.

A FEW YEARS ago canvas plants for the concentration of slimes were much in favor and are still in use in many places; but the introduction of various hydraulic classifying devices, for the purpose of properly classifying pulverized material and the subsequent concentration of the several sizes on machines adapted to the various grades of material, has demonstrated that where the classification is properly performed and the concentrating machines are adapted to the work, there is little use for the canvas slimes tables below the mill, as the values are nearly all recovered before the canvas slimes tables are reached, if the material has been crushed fine enough to release the values.

BY the use of a timber-framing machine the cost of framing mine timbers can be considerably reduced. With a properly equipped machine, a timber for the square-set system—a post, for instance—can be framed at both ends in from two to three minutes. Ties and caps also can be as quickly framed, ready for use. The machines are as accurate as hand work and more economical of time.

THE fact that a company owns all the iron in the neighborhood of its smelter, and that it is situated 60 miles nearer the coke ovens of the region in which the property is situated, neither prevents other smelters from operating, nor does it insure coke at less cost than that paid by other competitors who are at a greater distance. This has been demonstrated many times and is one of the peculiarities of railway economy.

IN working an ore deposit or vein by the open-cut or glory hole method, where the face becomes so far removed from the mill hole that the rock no longer runs to it by gravity, or where the rock is shoveled into cars, horse scrapers may be used to advantage if the rocks do not break too big to be conveniently handled. A 2 horse scraper should handle about seventy-five to eighty tons of ore per shift, or as much as five men will shovel.

WHERE ores are so soft as to require no blasting, the greatest care is necessary in their extraction under all conditions, excepting in open-cut work. If stoping underground is attempted in rock of this character, the stopes must be carried up in small vertical sections and should not spread over a broad superficial area. Timber must be promptly placed and filling run in as soon as possible and kept well up with the progress of excavation.

UNDOUBTEDLY in most cases drill holes may be so pointed as to throw rock in any desired direction when blasting. Ordinarily the rock is projected away from the hole in the direction in which the drill is pointed. This is more particularly the case in blasting boulders and outcropping rocks on the surface. In drifting and shaft sinking this theory is exemplified in the V-shaped cut holes which are first thrown out from the center of the face.

SOME gold quartz mills have no concentrating devices whatever, the values being saved on amalgamating plates alone. This works well where the gold is wholly free—not infrequently the case in the oxidized zone of many mines, but with depth sulphides usually appear, and more or less gold is associated with them. While it is generally admitted the gold in sulphurets may be recovered by amalgamation, it rarely pays to undertake this method of recovery in competition with other less expensive treatment.

ROADS, ditches, flumes, dams, buildings, machinery and other improvements on and for the benefit of unpatented mining claims may properly be charged to assessment work, and any legitimate labor performed or improvements made which is properly chargeable to annual assessment is properly a portion of the $500 worth of work necessary to be performed prior to application for patent. This $500 worth of work may be continued at the rate of $100 annually for five years, or it may all be completed within a week if desired, and application made for patent at once.

WHERE rock is to be broken down in open cuts, if a mill hole is not available through which the ore can pass down to a loading chute at a level below the bottom of the cut, inexpensive chutes may be built at the side of the cut which will permit the inexpensive delivery of the broken ore to cars run under the chute. It does not pay to build substantial or permanent structures of this kind. In some instances where ore is being mined in open cuts and the ore shoveled from the floor of the cut into cars, it will pay to run a tunnel at a lower level and put a raise through to the bottom of the cut, so that the ore mined on the stopes of the cut will run by gravity to the chute built in the tunnel below, thus reducing the cost of handling.

A TUBE mill is mainly a cylinder nearly horizontal in position, having an inlet for the material to be crushed at one end, and an outlet for the finely pulverized material, either through screens in the sides or at the lower end of the mill. The cylinder is usually lined with some sort of hard material, such as chrome or manganese steel plates, and with the ore or other material to be crushed is introduced either balls of steel or cobbles of flint—generally the latter where the iron particles would be detrimental to metallurgical treatment. The cylinder is rotated by power. This type of mill is extensively employed in some districts to produce extremely fine pulp or slimes, and is largely in use in Western Australia for this purpose.

OIL is reported in successful operation in smelting copper sulphides at the smelting works of Kedabey & Kalaxent, 40 miles southwest of Elisabetpol, Russia. The petroleum used has specific gravity 0.882; it contains 87.4% carbon, 12.5% hydrogen, 0.1% oxygen. The 5% copper ores are smelted; the leaner are worked by lixiviation. The furnaces are fired by spraying crude petroleum under a pressure head of 30 feet, at each side of the waste-gas flue, the spray being approximately injected tangential to the furnace walls into the melting chamber, where it is at once gasified, the two flames sweeping around the circumference of the furnace, meeting at the opposite side and returning across the middle in a straight line to the flue where the waste gases escape into the roasting furnace and thence into the chimney.

THERE is nothing less certain in their accuracy than the readings from the dial of an aneroid barometer. It is a very delicate instrument, and its adjustments are easily disturbed. When carrying a barometer about from place to place, climbing mountains, etc., it is impossible for the instrument to be kept in accurate adjustment. Temperature also affects the barometer, and corrections must be made for changes in temperature and slight corrections for humidity. To measure the difference of altitude between two places with a barometer, first measure the air pressure (P) at the lower station, and then the air pressure (p) at the upper station. Calling T the indicated temperature in degrees Fahrenheit, the vertical distance between the two stations = $(60{,}360 + [T - 32°]\ 122.68) \log \frac{P}{p}$.

WHERE it is the intention of a claimant to adverse the holder of a conflicting mining claim, the adverse notice must set forth the nature and extent of the interference or conflict; whether the adverse party claims as a purchaser for valuable consideration or as a locator; if the former, a certified copy of the original location, the original conveyance, a duly certified copy thereof, or an abstract of title from the office of the proper recorder, should be furnished; or if the transaction was merely a verbal one, he will narrate the circumstances attending the purchase, the date thereof, and the amount paid, which facts should be supported by the affidavit of one or more witnesses, if any were present at the time, and if he claims as a locator he must file a duly certified copy of the location from the office of the proper recorder.

ALUMINUM and magnesium are readily attacked by a solution of potassium cyanide in the cold; but of the other metals only copper and zinc cause an appreciable evolution of hydrogen, a double cyanide being formed. In the case of zinc, the action soon stops owing to the formation of the insoluble double cyanide $Zn(CN)_2 2KCN$ which protects the metal. At the boiling point the reaction is much accelerated. Certain metals e. g., cadmium and silver, will dissolve only in presence of air or oxygen; while mercury remains unattacked. Quantitative experiments show that when a strip of platinum is boiled with potassium cyanide solution, the surface gradually becomes pitted, and there is a decrease in weight. If the metal is then placed in a fresh solution and the boiling repeated, the loss of weight is greater and approximates to 0.030 gram per square decimeter per hour.

IT is a principle of the mining law that the owner by grant of mineral in a vein beneath the surface must have the use of some portion of the surface, in order that he may reach the minerals beneath. To do this he has a right of way of necessity. (Wardell v. Watson, 93 Mo. 107, 5 S. W. 605.) This way of necessity should not be of larger dimensions than is reasonably requisite. (Monmouth Canal Co. v. Harford, 1 Cr. M. & R. 614-637.) This right or privilege cannot be extended, however, to the use of other lands belonging to the grantee, for the purpose of transporting ore; nor can it be asserted for any purpose not legitimately associated with the search for and extraction of the minerals. It is also in accordance with court decisions that the right to the use of necessary surface is not restricted by reason of the fact that the surface owner had granted a right of way for a tunnel by means of which ore could be removed from the mine.

MUCH depends upon the conditions in blasting gravel banks. A blast was laid several years ago in Trinity county, Cal., in which a tunnel was run into the bank a distance of 100 feet. At the face of the tunnel the gravel bank was 86 feet high. At the mouth of the tunnel the bank was 10 feet high. In the tunnel, 30 feet from the mouth, a crosscut was run 30 feet each way, and at 60 feet crosscuts were driven 40 feet right and left, and again at the face 40-foot crosscuts were run in similar manner. Four tons of low nitro powder were placed in the first and second crosscuts on both sides of the main drift, but owing to a shortage of powder, none was placed in the crosscut at the face. It was the intention or expectation to blast the bank as far as the second crosscut, and when this was hydraulicked away, to extend the excavation and lay the second charge. In each wing of the two crosscuts was placed 50 pounds of No. 2 powder to act as a "primer." The wires were connected and several holes drilled into the roof of the main drift several feet from the entrance. This was blasted down, the debris forming a substantial tamping for the entire mine. When the blast was fired the ground broke an area considerably in excess of the outlines of the tunneling operations. Not only was the ground broken over the blast, but to the face and far beyond. The total amount of gravel dislodged and broken up was 94,000 cubic yards.

The Transvaal Gold Mines.

Written for the MINING AND SCIENTIFIC PRESS by THEO. F. VAN WAGENEN, E. M.

The object of the present paper is to review the industry in the Transvaal, which is that part of the South African upland plateau lying between the Vaal river on the south, and the Limpopo on the north. The first mentioned is an affluent of the Orange river, which flows into the Atlantic, while the other empties into the Indian ocean. The continental divide of the country therefore lies between the two streams, and when it is carefully traced out it appears that the Witwatersrand (White Water range), or the Rand, as it is popularly known, is a section of this divide. Now the gold mining region, and the town of Johannesburg, are situated directly on the crest of this range, but when there, one has no suspicion of the fact, for there is no outlook in any direction, and no appearance of hills or of a summit. In fact, the country seems quite level and the several lines of railroad coming up from Cape Town and Durban, on the south, and going out to Pretoria on the north, have their terminals right in the heart of the city, while a suburban road runs along the invisible summit, connecting the principal city, Johannesburg, with the numerous smaller towns that are strung along it for 30 miles or more.

In a broad way the mineral formation may be said to outcrop along the southern slope of this divide for an equal distance at least, and, dipping to the north at an angle of 25° to 55°, disappears in the bosom of the plateau.

Without going too much into geological details, which as yet are not settled and are not likely to be for many years, it may be said that this outcrop has been fairly well traced out for about 20 miles, and with less certainty for perhaps 20 more. It is crossed by numerous faults, which cause the line of strike to assume a most irregular course, and there are great variations in the angle of the dip. Away to the east and west it is the popular fancy (for which there is much warrant) that it curves around to the north, and in the opinion of those optimists, who are always found in a gold mining locality, and, for that matter, in almost every locality that has any good points at all, it will ultimately be chased around until a complete circuit is proved up, that will measure from 100 to 150 miles in circumference, and will include a basin of a roughly oval shape, with diameters ranging from 30 to 50 miles, within the limits of which the most sanguine of the Johannesburgers have calculated that there are several billion tons of payable quartz carrying on an average not less than half an ounce of gold per ton, and unlimited billions more of lower grade. And when the boomers get down to details, it is not at all easy to disprove the position they take, which is, concisely stated, that the Rand goldfield contains, and will yield, as much of the yellow metal as has been produced by all the other mining districts of the world, heretofore, since the dawn of history.

It is easy to comprehend what a field of operation this cheerful view of things opens to the speculator as well as the miner, and it must be admitted that full advantage has been taken of it.

The process of exploitation, development and flotation has been as follows: Originally the entire region was owned by Boer farmers and was used mainly for pasturage. The Transvaal mining law permits mineral exploration on farm lands, and so outcroppings were discovered here and there, and the history of the region as a gold field began. It does not appear that there were any evidences of work by Ancients in the vicinity, as is the case in most other parts of the African continent. When taking up land, the prospector, or his assign, the promoter, generally got a bond on the tract from the farmer, so as to quiet forever all matters of title, and then took the proposition to London, where a company was formed under the English corporation law, and a working and developing fund provided by selling a portion of the capital stock to the public. Thus originated what are known as the "outcrop mines," including most of the properties that have so far become productive and profitable. With a traceable outcrop 20 to 30 miles long, a very good beginning was made by the promoters and speculators, as may be imagined, but at last the time came when all the known outcrop was capitalized and floated off, and then began the era of the "Deeps."

The Transvaal mining law does not recognize any extralateral rights. Consequently all the outcrop mines must in due time become exhausted, but, wherever one of these had become a success, it was an easy matter to organize and float off, on the strength of its history and record, another company in its rear, on the dip of the reef. Accordingly, more acreage was blocked out, and drilling operations were started to cut the reef in depth and prove the value of the ground by demonstrating the continuity and value per ton of the ore-bearing stratum. The funds for conducting these preliminary operations were provided by the organization of a small local syndicate, or the deal was financed by one of the outcrop companies. But as soon as sufficiently favorable evidence in the way of drill core and assays was secured, the new area was floated off in London in the same way as the outcrop areas had been, the general public being called upon to provide the means to sink the deep shafts required to reach the ledge at depth, as well as all the costs already incurred, and also their share of the capitalized value of the land. A good deal more capital was required for these "Deeps" than for the outcrop propositions, as may be easily understood, for shafts ranging in depth from 1500 to 2500 feet had to be sunk to reach the ore-bearing zone, before the process of its development could even begin, besides which, each property had ultimately to be equipped with the regulation hoisting and milling plant. But the public of England went merrily into the game, and, by proper and entirely warrantable manipulation of the market, a great deal of support was obtained from investors that could be reached through the bourses of Paris, Berlin and other continental cities. At one time efforts were made to attract American capital into "Kaffirs," as these shares were called, but it did not succeed.

These "Deep" mines generally covered from 200 to 300 acres, and, of course, in due time, all the available ground immediately behind the apex mines was floated off and the promoting fraternity were threatened with a termination of their activities, unless the public could be interested in a new series. These were duly brought out under the name of "Deep-Deeps." Necessarily each had to be provided with even a larger capitalization than an ordinary plain "Deep," but it proved easy at the time to raise money for these enterprises, or rather to float off the companies, for, as the task of reaching the ore zone with shafts had now become a matter of five to seven years, only a small part of the cash for the entire operation was called up at the time, and the large financial houses in London and elsewhere carried the bulk of the shares for the first line of investors, all of whom expected to be able gradually to pass on a part of their liability at a handsome profit to the general public in time to meet the deferred payments. It was a grand scheme, quite worthy of the magnificent resources of the mineral field upon which it was based, and quite liable, or even certain, to succeed, but for the usual chapter of accidents that always occurs sooner or later, but which you and I and every one else hopes to be able to dodge, though we fully expect to see the other fellows caught.

In this case the "Chapter" consisted of the Boer war, which was expected to be all over in six months, but which lasted more than three years. Its effect on "Kaffirs" is well known, and need not be enlarged upon here. But, while the Rand shares were magnificently sustained by the London financiers during that long struggle, and while the field has been thoroughly rehabilitated and brought back to its ante bellum condition in the three years that have succeeded, the general public, upon whose broad shoulders the real burden of the task was to be placed, have not as yet come into the game as freely as was expected. This, of course, has been due to the costs of the war, which for a time has absorbed the bulk of the savings of the investing public. However, the job of the mastication and digestion of the remaining "Kaffirs" that are hanging over the market will be accomplished in due time, for the Transvaal goldfield has wonderful merit and possibilities, and so long as the gross output continues to grow, and gold remains the sole standard of value, a steady absorption will proceed until the manipulators of the London mining market have got the mass of the shares placed as they wish. But, so serious has been the check in the progress of the game, and so heavy has been the burden upon a number of the investors, that it is not likely another series of "Deeps" will ever again be attempted.

The general mining situation in the field may now be summarized as follows: First, quite a number of the outcrop mines are rapidly approaching exhaustion, but they have paid so well, and will continue to do so up to the last minute, that their closing down, when it occurs, will not injure the market or injuriously affect the reputation of the district. Second, fifteen of the "Deeps" have been brought to the productive stage, and while it is now fairly well recognized in inside circles, and quite extensively among general investors, that the net profit per ton on the "Deep" ores is not going to equal that obtained from "Outcrop" quartz, yet the series will pay well in the majority of cases. Third, while no "Deep-Deeps" have yet been carried anywhere near the producing stage, and will not begin to come in for another three to five years, there is good hope for the shareholders in that series, and in any event it is certain that as a whole they will pay expenses and hence will be operated, in which case the world at least will get the benefit of the gold recovered.

(TO BE CONTINUED.)

Mining Coal from a River.

J. Hague, of Plymouth, Pa., has a large dredge completed and has begun to dredge the river for coal, says Fuel. He has been working for some time on his "coal breaker," getting it in readiness, but was detained on account of being unable to secure the proper machinery. He has placed a boiler and engine on the flat, which will generate power for working the dredge and operating the machinery. The coal will be "picked" from the river by a steam shovel and will then be carried to the rollers by elevators, where the coal of the larger sizes will be broken and run through a screen and separated according to sizes. After the coal is separated there will be chutes to receive each size and to run the assorted coal to flats lying along both sides of the dredge. Mr. Hague has been to considerable expense in fitting up the dredge, but he contends that there are thousands of tons of fuel in the river that can be taken out with a good profit.

Some Primitive Mining Engineering.

Written for the MINING AND SCIENTIFIC PRESS.

Several years ago when in Tuolumne county, California, I came across three pocket miners who had on hand a piece of mining engineering which caused them considerable anxiety, but which they worked out in a primitive way to their own satisfaction, in a manner which must have delighted the old German author, Agricola, could he but have been a witness to this operation. The methods of these three miners were remarkably similar to those pictured in the famous old work of that writer, "De re Metallica."

The problem confronting the miners, as I now remember it, was about as follows: They were developing a pocket mine on Bald mountain, near Sonora. The vein coursed along the side of the mountain and dipped steeply toward the canyon. They wished to run a tunnel to strike the vein, but did not know how far this tunnel would have to run to reach it. The only instruments I saw them use were a small pocket compass, secured to a strip of lath about 2 feet long, and which was provided at each end with a rude sight—a tape line 50 feet long, and a piece of string, to one end of which was attached a rock weighing about four ounces—this to serve as a plumb bob. They had already made an open cut, the beginning of which was in soft ground, but the back end where the tunnel was to go under cover had become hard and tough, and it was this fact apparently that caused the desire to know about how long the proposed tunnel must necessarily be to reach the vein.

It was my good fortune to arrive just as the engineering difficulties began, and I was so much interested in the operation that I offered neither assistance nor suggestion, preferring to watch how the thing was done, thinking it might be useful knowledge to me some time when I had no better means at hand than they had.

The first thing they did was to set the compass on a piece of timber set on end, on the dump. This was really a needless operation, as it only gave them approximately the direction of the proposed tunnel as related to the meridian. I have forgotten the exact direction now, but it was easterly. The next operation was the driving of a peg or small stake into one side of the dump at the place where its floor joined the slope of the hillside—the place where they first began to dig away the earth to start the cut. Into this stake they drove a nail, after the manner of surveyors, but which seemed to me an unnecessary refinement in the process. From this nail they carefully measured up the hillside in the direction of a small shaft they had started down on the vein, a post on the outcrop being plainly visible from the dump at the tunnel site. Two men did the measuring, the third standing at the peg to keep the others in alignment. They made no attempt at leveling, but took the measurement on the slope of the hill. When this had been accomplished we all climbed up to the shaft. The distance reported on the slope was, I think, 285 feet.

At the shaft one of the men fastened his plumb bob to a nail and let it drop down the shaft until it nearly touched the foot wall. When the rock at the end of the string came to a state of rest, they carefully measured the distance from the collar of the shaft on the foot wall side to the plumb bob by means of the tape, being careful not to touch the string. This distance was 10 feet. They then as carefully measured across the shaft on the level and this distance was found to be very close to 5 feet. The vertical distance along the string was 8 feet 8 inches. This, they said, showed the vein to gain toward the mouth of the tunnel 1 foot in each 2 of inclined depth (a 60° slope, though they knew nothing of degrees).

We all returned to the lower dump. I was much interested in ascertaining how they expected to work out the problem with so limited information. Arrived at the tunnelsite, a careful measurement was made along the edge of the cut, this measurement being on the slope angle of the hill, which, fortunately for their purpose, was quite uniform throughout. They measured on this slope a distance of 10 feet from the peg. At this point they drove a second peg at the side of the cut, and then tacked a narrow strip across the top of it horizontally, so that one end of it would project over the edge of the cut. From this the plumb bob was swung and when it was quiet the spot beneath it was marked, and both the vertical height of the cut at that place and the distance from the peg No. 1 were measured. The former distance was found to be about 5 feet. The

horizontal distance was found to be about 8 feet 8 inches.

From this data they now figured that if in measuring on the slope of the hill a distance of 10 feet they gained a vertical height of 5 feet they would be when vertically under the shaft 142 feet 6 inches below the surface, or just one-half of the distance as measured on the slope, which fact had been clearly demonstrated by the measurements made in the cut. The horizontal distance gained on a 10-foot slope being 8 feet 8 inches, the distance gained in going 100 feet they argued would be "nearly 90 feet, or say about 87 feet, and in going 200 feet twice that, or 174 feet, and in 85 feet more about 72 feet, or a whole distance of 246 feet." (The actual distance based on the measurements was 246 feet, so it will be observed these miners were good guessers.)

"Now," they said, "the vein dips toward us 5 feet in 8 feet 8 inches of vertical depth. As the distance from the level of the tunnel floor to the collar of the shaft is 142 feet 6 inches, this offset of 5 feet will be repeated about sixteen or seventeen times." To arrive at this latter conclusion required considerable figuring, discussion and dispute, but it was finally agreed that sixteen and one-half times was about right. This multiplied by 5 gave 82½ feet to be deducted from the whole distance of 246 feet, which was 163.5 feet. As the cut had already advanced about 22 feet, this also was deducted, leaving a total distance of 143.5 feet to run to reach the vein.

The tunnel was run and it cut the vein in 140 feet from the point of going under cover, or 3½ feet less than they had calculated, owing to the vein taking a slightly flatter dip than that in the upper part of the shaft. These miners were Italians, and good workmen. Although their education was limited, they possessed an amount of ingenuity and practical sense which carried them over many difficulties in their work.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

NUMBER IV.

Written by T. H. Oxnam.

Precipitation of Silver and Gold.—There are six zinc boxes, five being used for the weak solution and one for the strong solution. The five weak solution boxes, constructed of No. 10 sheet steel, are 2 feet wide and 18 feet long over all. Each box contains eight compartments, each compartment having an available zinc capacity of 24x24x18 inches, equivalent to 5 cubic feet. Six compartments only are filled with zinc shavings, and each box, when freshly dressed, therefore contains 36 cubic feet of shavings, making a total of 180 cubic feet of zinc shavings in the five weak solution boxes.

The strong solution zinc box consists of seven individual round boxes or compartments, placed in series, each compartment being 28 inches in diameter and 24 inches in depth, and having an available zinc capacity of approximately 5 cubic feet. Only six of the compartments are filled with shavings, the last compartment being reserved, as above stated, for the addition of the quantity of cyanide required to bring the strong solution up to standard strength. The strong solution zinc box has, therefore, a total of 30 cubic feet of zinc shavings.

Records are kept of the quantity of weak and strong solution daily passing through the boxes, together with their assay values before and after precipitation. These records for the year (1904) show that 91,793 tons of weak and 22,251 tons of strong solution passed through the boxes, which is equivalent to an average of 251 tons of weak and 61 tons of strong solution every twenty-four hours. During this period, the flow of solution through the boxes was naturally interrupted on various occasions for a short time. due to the ordinary cleanups, dressing of the boxes, etc., as well as various minor, unavoidable delays. Without taking such stoppages into account, however, the average rate of flow of the solution through the boxes equaled 1.4 tons of weak solution per twenty-four hours per cubic foot of shavings, and 2.03 tons of strong solution per twenty-four hours per cubic foot of shavings.

The actual rate of flow, however, exceeds these figures, as it is here assumed that the boxes were at all times kept dressed with the maximum amount of shavings, which, strictly speaking, was seldom the case.

The shavings used are cut on an ordinary zinc lathe, from No. 9 sheet zinc—the size of the sheets being 18x84 inches. Ordinarily, six sheets are wound on the mandrel of the lathe for one cutting. One boy working twelve hours cuts a sufficient quantity of shavings to supply both the leaching and agitation plants, which together require an average of about 120 pounds of shavings per twenty-four hours.

It is found best to keep only a few days' shavings on hand—freshly cut shavings giving better results than those which have been cut for some time. The customary practice of moving the zinc from the lower to the upper compartments, when dressing the boxes, is not followed, fresh zinc being added as required to the top of each compartment.

The strength of the solution running through the weak boxes will average between 0.25% and 0.30% of KCN, while that of the solution going to the strong zinc box will average between 0.35% and 0.45% of KCN.

The average assay values per ton of the solutions entering the zinc boxes are approximately as follows:

Weak Solution.	Strong Solution.
$1 of gold and 2.25 oz. of silver.	$1.24 of gold and 3.5 oz. of silver.

It is very seldom that any trouble is experienced with the precipitation of the contained values. As a rule the precipitation of gold is practically perfect, while that of the silver will average about 95%. When the percentage of precipitation falls off, it is usually due to the presence of an accumulated excess of lime in the solution.

Table IV gives the results of assays taken from each compartment of both the weak solution and the strong solution boxes, and shows the progress of precipitation in the successive compartments. These results may be taken as an average of those regularly obtained.

Cleanup of Zinc Boxes.—On account of structural difficulties the cleanup facilities are not as convenient as could be desired and it is necessary to handle the precipitates more than would otherwise be the case.

All the boxes are cleaned up twice a month. Before commencing on any one box, clear water is passed through it a sufficient length of time to displace most of the cyanide solution, which usually requires ten or fifteen minutes. The shavings in the first compartment are thoroughly washed, after which they are removed and the water bailed out into the next compartment. The precipitates are now conveyed by means of buckets to the cleanup box, where they are passed through a 20 mesh screen. A small percentage of "short" zinc passes through this screen, but the greater part of such product is here separated from the finer precipitates and is returned to the boxes. The first compartment is now filled with water and the zinc contained in the other compartments is gradually transferred to it and thoroughly washed, the precipitates from each compartment being carried to the cleanup box, as before mentioned. In order to reduce to a minimum the rapid oxidizing effect resulting from exposure of the wet zinc to the atmosphere, the washed shavings are at once placed in the highest vacant compartment of the zinc box and covered with solution.

The precipitates accumulating in the first compartment from the washing of the shavings, after being allowed to settle for a short time, are also removed to the cleanup box. This latter is provided with three smaller settling boxes, placed in series, which take the overflow from it. The bottom of the cleanup box is tapped by a 4-inch drop pipe, which discharges directly into two large drying pans beneath.

The product is now dried as much as is practicable and then mixed, carefully sampled, assayed and sold on the premises to one of the large ore buying companies.

The moisture contained in the dried precipitates has averaged 0.27% during the past year.

The cleanups, as would naturally be supposed, are quite bulky. The net, dry weight of precipitates in each cleanup averaged between 1100 and 1200 pounds avoirdupois during the past year.

Considering the fact that the precipitates receive no treatment whatever beyond being passed through a 20 mesh screen and the simple drying as above mentioned, it is rather surprising that they carry such a comparatively high percentage of fine metal. During 1904 the assay returns on which the sale of the precipitates is based have averaged slightly over 20,000 ounces of silver and approximately $8000 of gold per short ton. By actual weight, therefore, the percentage of fine metal contained in the dried product recovered throughout this period was approximately 68.57% of silver and 1.33% of gold, making a total of 69.90% of both metals.

To the best of my knowledge this is the highest percentage of precious metal contained in any cyanide precipitates regularly obtained in ordinary zinc precipitation.

Two cleanups during 1904, of a combined net weight slightly exceeding 2300 pounds, gave an average assay value of 22,200 ounces of silver per ton, making the fine silver content equal to 76.12% by weight of the precipitates.

Having noticed in recent papers of the Institute the discussion of the number of ounces of fine metal handled per man hour while removing the precipitates from the zinc boxes or filter presses, the following data are offered.

A record kept for some time of the labor employed in cleanups shows that on an average four men (one American and three native helpers) would readily remove 1200 pounds (net dry weight) of precipitates from the boxes and have the product in the drying pans in eight hours. Based on the average assays of the precipitates for the year, this means that in thirty-two man hours approximately 12,200 ounces of fine metal would be handled, being equivalent to a duty of 381 ounces per man hour. This rather high duty is, of course, due entirely to the fact that the precipitates contain such an exceptionally high percentage of precious metals.

Table V gives the result of a sizing test made on one lot of precipitates, which ran somewhat lower than the average in silver:

TABLE V.—Sizing Test of Cyanide Precipitates.

Assay value of precipitates per ton was $8622.90 of gold and 19,488.65 ounces of silver

Size of Material.	Weight.	Assay Value. Gold.	Assay Value. Silver.

Tonnage and Extraction Percentages.—During 1904 a total of 34,500 tons of sands were treated in the leaching plant. This tonnage would have been considerably greater had it not been that during this period, aside from the ordinary stoppages in the mill due to general necessary repairs, the mill was closed down at different times for intervals aggregating a total of fifty-seven days for the entire fifty stamps, from causes beyond our control, such as shortage of water power during the dry season, washouts along the railroad and power ditch during the heavy rains, etc.

The extraction for 1904, indicated by the assay differences between the sands charged into the leaching vats and being discharged, was 95.5% of the gold and 52.5% of the silver values. The combined total value of the precipitates recovered during the year checks closely with that called for by the sand assays.

The assay value of the sands treated during this period has averaged approximately $2 85 of gold and slightly more than 16 ounces of silver per ton.

The total returns called for by the zinc box precipitation records correspond very closely to the actual returns from the precipitates recovered. During 1904 the returns from the precipitates were practically 1% less in gold and 0.5% more in silver than those called for by the precipitation records.

This difference in the gold is accounted for by the fact that the precipitated solutions are only occasionally assayed for gold, it being ordinarily assumed in the daily precipitation records that the precipitation of the gold is perfect, while, as a matter of fact, the solution leaving the zinc boxes will very probably carry an average of a few cents of gold per ton.

Consumption of Cyanide, Zinc and Lime.—The office records show that for 1904 the consumption per ton of sands cyanided was as follows: Cyanide, 2.95; zinc, 0.96; lime, 4.33 pounds.

It will be remembered in this connection that during this period sodium cyanide of a strength equivalent to 125% of potassium cyanide was exclusively employed. Expressed in terms of potassium cyanide, this consumption would, therefore, equal 3.69 pounds of potassium cyanide per ton of ore treated.

The Black Hills of South Dakota were described as auriferous as early as 1867, but no note was taken of the fact until 1875, when the first movement of miners into that country occurred. The Hills were included in the Sioux reservation,

An Experience in Water Recovery.*

Written for the MINING AND SCIENTIFIC PRESS by GEO. S. BINCKLEY, E. M.

To call attention to the importance of water recovery in milling operations in the southwest is superfluous, if the reader happens to be familiar with the conditions in the arid region. It is, however, not always fully realized by others that very frequently the output from a given property is limited absolutely, by the water available, and not by the mechanical equipment and labor employed. A mere trickle of water, carefully husbanded, may be sufficient for five or ten stamps, but when the limit of hydral economy is reached, the production has also touched its limit.

When the mine operator is so fortunate as to have a clean, hard quartz to deal with, little difficulty is to be found in saving practically all the water circulated, except that lost through evaporation, and even this loss may be minimized by keeping down the surface of the water exposed to the atmosphere to the lowest possible limit, and preventing, so far as possible, the circulation of air over the exposed surfaces.

An instance of easy recovery is seen at Congress, Ariz., where separation of clear water is effected continuously by passing the slimes through a series of V-shaped tanks over wide, shallow wiers, serving to separate the tank into a number of divisions. The thick slimes drawn from the bottom of these tanks carry, naturally, a very considerable percentage of water, which, under the system in use at the time of the writer's last visit, seemed to be for the most part lost through evaporation. Observation indicated, however, that the proportion of slimes to the total of the ore was low, which, as mentioned before, simplifies the problem. The accompanying engravings illustrate the situation at the Congress mine, Arizona.

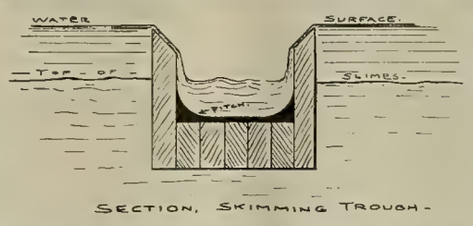
Quite another condition obtains, however, where the ore treatment produces a large proportion of impalpable slimes. The writer has seen tailings pass away from a certain well-known mill on the Mother Lode, that would not have deposited 10% of the slimes carried if passed through the recovery plant of the Congress mill. Where, in addition to the lightness and impalpable fineness of the slimes, the water is strongly or even moderately acid, the difficulties of recovery are very greatly increased, and ordinary methods entirely fail to produce clear water from the slimes.

Dr. Pierre de Peyster Ricketts of New York described to the writer, some years ago, a device he was then using at Nacozari, Mex., for thickening pulp in a concentration mill. This was merely a tank, about 8 feet diameter and 16 feet high, provided with a circular trough outside and near the top, and having the upper edge planed down to an exact level all around. Pulp was led through a launder to a wooden box, about a foot square, placed in a vertical position in the tank and reaching from the surface to something more than half way to the bottom, so that the descending column of pulp deposited its heavier constituents in the lower part of the tank, while only the lightest slimes were carried by the slow and uniform current to the top of the tank, overflowing here into the circular trough before mentioned, while a constant stream of thick pulp was discharged through a suitable opening below. This scheme worked very satisfactorily on the Nacozari ores, and would probably produce a continuous and practically clear flow of water from the pulp of the harder, more siliceous class of ores.

Some little time ago, the writer was confronted with the necessity of making a series of tests to determine the susceptibility to milling treatment of some ores which, although treated by this process previously, were known to have yielded but a low proportion of their assay value. Absolutely no reliable data existed on the actual extraction secured. A seeming paradox existed in the apparently higher extraction from base sulphide ores by amalgamation than from soft and thoroughly oxidized ores from near the surface. The first obstacle to the proposed tests was lack of water at the mill, which was formerly supplied through a pipe line 2½ miles long, from a source over 1000 feet lower than the mill. The salt water formerly used, however, had entirely destroyed the usefulness of this pipe line, so the mill was left stranded high and exceedingly dry.

After the expenditure of some time and labor, a limited flow of water was secured from the bottom of a small and shallow shaft sunk for this purpose, and another trickle of saline water was secured from a wet spot in the canyon above the mill, so, making a careful measurement of the flow from these sources, the writer decided, at last, to proceed with the tests.

In the design of the recovery plant, the system was so laid out that the tailings, once raised by a bucket elevator from the sluice to the upper part of the mill, would run by gravity to the sand-settling tanks, and



the slimes would flow thence through the slime tanks, delivering the clear water to the mill tank, which in turn gave a gravity supply to the mill. The arrangement of the tanks is shown in the accompanying diagram, and the engraving from a photo shows the relation of this part of the system to the mill.

The size of the sand tank was 5 feet deep, 10 feet wide and 20 feet long, divided into eight equal compartments, so arranged that a continuous flow could be maintained through the whole or part of the compartments. The discharge of sand could then be accomplished without interference with the flow of slimes. Each compartment had a discharge door in the bottom, and the bottom of each was provided with a regular filter rack, the same as that used in the percolation vats for cyanide work, the object being to draw off as much clear water as possible by direct filtration.

The slimes passing from the sand tanks were delivered through a launder to the slime separator. This was practically Dr. Ricketts' device, before referred to, except that it was not as deep, and was provided with a pyramidal down-take box (see sketch), so that the velocity of the descending column of heavy slimes should be gradually decreased, and that of the ascending column outside the box also uniformly decreased as it approached the lip of the tank. This part of the system was carefully worked out, and by careful attention to the blowing off of thick slimes in the bottom of the tank, it was expected that a flow of clear water would be secured over the lip and into the overflow trough.

Unfortunately, difficulties developed. In the first place, after but about a half hour of operation, the filters in the bottom of the first sand tanks clogged completely, and no further percolation was obtained, blasting all hope of help from this source. In the second place, a persistent tendency to indefinite suspension was exhibited by the slimes, as, to all appearances, as heavy slimes were passing over the lip of the separator tank as flowed in from the sand boxes. It didn't take long to come to the conclusion that not only was something wrong, but that an immediate remedy was demanded. As a makeshift, the largest of the mill tanks was cut off and converted into a slime tank, and a down-take box was so placed as to lead the fine slimes discharged from the separator tank toward the bottom of the big slime tank. This tank being a large one, the scheme saved us for a while, but the overflow pipe to the mill tank being on one side, caused a local current which began to carry slimes over.

About this time, things looked bad for a water supply for five 1080-pound stamps, two 6-foot belt concentrators, an arrastra and a gasoline engine. The available supply of fresh clear water was about the size of one's little finger, dripping out of the end of a 2-inch pipe, and we were rapidly accumulating about 30,000 gallons of slimes. Also, when water troubles were seeming pretty hopeless, it developed that our beautiful, oxidized "free-milling" ore carried a lot of finely divided copper sulphate, which made a sight of the plates to weep over—considerable galena began to turn up with this same ore and a fair amount of bornite developed. Then, the water became so acid that the slimes would hardly go down at all, and a temporary shut down became imperative.

Owing to the remoteness of the mines, no supplies were immediately available, so a couple of barrels of soda ash (sent out by mistake long previously) were brought to the mill and used to neutralize the water.

Together with the minor improvements made in the mechanical part of the system, we were able to make another start, this time on a harder sulphide ore, not highly siliceous and very slimy. In justice to the original arrangement as a whole, it must be said that although the light and impalpable slimes gave us so much trouble, an amazing amount of mud was deposited wherever the current was allowed to come to rest, and an actual determination of the proportion of slimes to sands in the original ore would doubtless be surprisingly high.

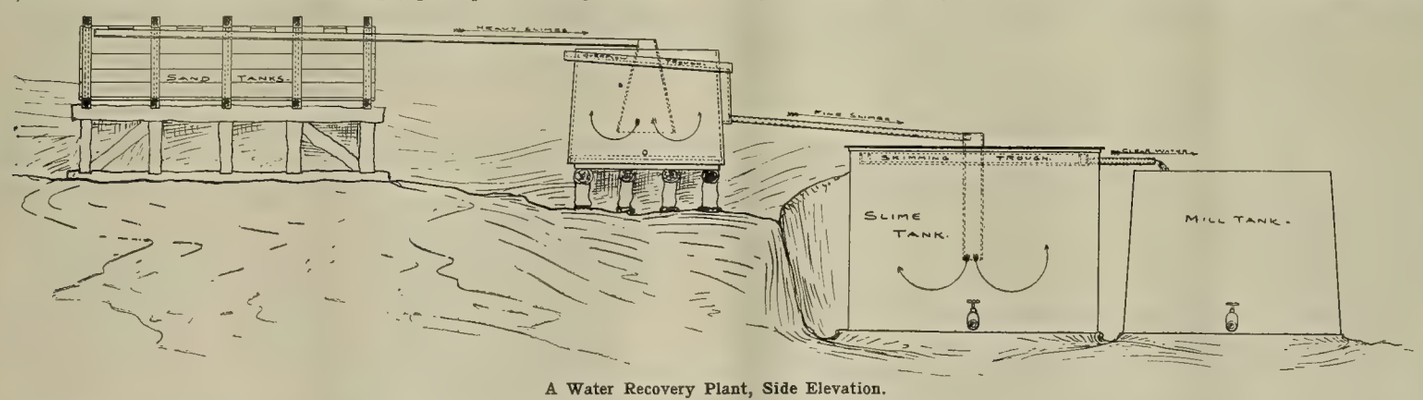
Before serious trouble could again develop, an arrangement was constructed and placed in position in the big slime tank, which the writer calls, for lack of a better name, a "skimming trough." This was a circular trough about 6 inches deep, 6 inches wide and in the form of a ring 16 feet 6 inches diameter. It was built up of 1-inch lumber and bevelled, as shown in the section on the upper lip, to about 45°, and the bottom rendered water-tight by a coating and fillet of pitch inside. This circular trough was then placed and held in position in the large slime tank in such a manner that the lips of the trough were exactly level, and a pipe connection provided from the interior of the trough through the side of the slime tank to the mill tank (see diagram). It must be understood that after being secured in position, made approximately level and connected up with the pipe to the mill tank, water was allowed to rise in the slime tank to the lip of the trough, which was then planed off to an absolute level, both sides.

When the arrangement was tried, it was found to work well, for so long as a thin skim of clear water lay on the surface of the slimes, clear water only would flow over the lip of the trough, even when over thirty gallons of water per minute was passing. The length of wier (over 100 feet taking both lips of the trough) was so great that the depth of flow over the lip probably did not average as much as $\frac{1}{32}$ inch, and localization of current was entirely avoided. When the first trial of this part of the system was made, it appeared that the problem was solved, but its limitations were soon developed.

In few words, it became clear, that with a certain slime, a definite and fixed relation exists between the amount of clear water that may be continuously taken off and the total volume of slimes that is undergoing precipitation. This fact was beautifully illustrated by observation of the working of the system through one shift.

The mill was not run at night, so for half the time the contents of the big slime tank were quiet and had a chance to settle. In the morning the water would be clear for several feet down, then, as distinct as the line separating oil from water, the slimes would begin. As the hours passed by with the mill in operation and the clear water flowing through the skimming trough from the slime tank, the plane of the slimes would rise, and if there was no wind to disturb the surface of the water, the rise of the slimes would be so even and uniform that clear water would be discharged up to the last moment, when the slime plane would actually reach the lip of the skimming trough. But once this point was reached, the slimes would flow over. Every scheme that ingenuity could suggest was tried at this point, but the fact remained that the uniform upward flow of the mass of slimes and water was more rapid than the rate of precipitation of the suspended particles.

In an attempt to conquer this difficulty, recourse was even had to the capillary siphon, strips of burlap being laid over the lips of the skimming trough, raising the water from a fraction of an inch outside of the trough over the lip and letting it flow down inside. But if the texture was sufficiently fine to act as a



A Water Recovery Plant, Side Elevation.

*See illustrations on front page.

filter, clogging would soon result, and, if open, the slimes would pass the siphon.

As mentioned before, some effect was obtained in the neutralization of the water with soda ash. When the supply of this was exhausted, lime was produced by the calcination of sea shells, and some little was obtained from small amounts of superficial secondary calcareous deposit, a kind of "caliche." Finally, a kind of mess, made by cooking a variety of cactus called "petaya" in water, was added to the slimes. It had a decided effect on the slimes, as it is a powerful astringent, but after a day of its use, the mill looked like the interior of a steam laundry in bad order, as the petaya piled up great billows of foam at every point that the pulp or water was agitated—the discharge from the elevator looked like a cream puff; the boot oozed suds from every seam; the battery frothed at the mouth, and so did the choleric old millman.

However, care and patient study of every favorable condition soon made it possible to operate the mill without interruption, and some interesting results were observed in the treatment of these ores. It may be of interest to know that when the sulphide ores would assay, for instance, $35, the concentrates would go from $8 to $12. Also, higher results were obtained from the amalgamation of the base sulphide ores than from the soft, friable, oxidized ores, owing to the presence in these latter of free sulphur—sometimes as high as 17%. This, together with the fact that most of these ores contained copper sulphate and ferric salts, induced in the contained gold a repugnance to quicksilver that amounted to a hobby, and that nothing but a nitric acid bath seemed to cure.

With all these difficulties to contend with, further operations were abandoned, as the purpose of the tests was accomplished. The reasons why a 20-stamp mill was ever built on this property are interesting, but "that's another story."

A summing up of the results, as far as water recovery is concerned, shows that, even with a very slimy ore, it is possible to recover over 88% of the water circulated in the mill, neglecting evaporation, which in the case described was very low, owing to the high humidity of the atmosphere.

Furthermore, although every effort was made to intercept the slimes before reaching the last slime tank, there was deposited here an amount of slimes equal to about 12% of the total of the ores worked. It is also of interest that an examination of the tailings showed but 7.5% of the total loss in the slimes, 10.5% of the total loss in the sulphides in the tailings, while 82% of the total loss was in that part of the tailings composed of coarse sands.

An analysis of the clear water in the mill tank, made at the conclusion of the operations (the water having been derived originally from saline springs), showed the following results: Solids, 1.48%, containing:

	Per Cent.
Lead	Trace
Aluminum salts	Trace
Ferrous salts	.19
Cupric salts	.35
Magnesium salts	.16
Calcium salts	.21
Potassium salts	Trace
Sodium salts	.41
Undetermined	.16
Total	1.48

Also, gold, per ton of water, $0.20; silver, per ton of water, .05 ounce.

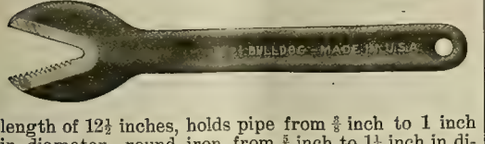
This is rather a discouraging mess for metallurgical purposes, but is interesting as demonstrating the solubility of gold in a solution of cupric and ferric salts.

In conclusion, the writer ventures the opinion that with ores of a normal character such a system as that used would probably secure a continuous flow of clear water for a 5-stamp mill, running twenty-four hours per day.

The rate of precipitation of the slimes in this case was very low, being only about .594 cubic foot of water per day per cubic foot of slimes undergoing precipitation. With a hard siliceous ore, it is likely that this rate would be at least doubled. With such a plant, however, it will be perfectly safe to base calculations on a flow of .206 gallon per hour per cubic foot of slimes in the last tank, even with very slimy ore, as the case described was probably extreme.

"Bull Dog" Wrench.

The Whitman & Barnes Manufacturing Co., having factories at Chicago, Ill., Akron, Ohio, and St. Catharines, Ontario, have recently added to their line and are placing on the market their No. 2½ "Bull Dog" wrench. This wrench, illustrated herewith, has a



length of 12½ inches, holds pipe from ⅝ inch to 1 inch in diameter, round iron from ⅝ inch to 1¼ inch in diameter. It is drop forged from special steel which the manufacturers have made to their own analysis, and is nicely finished in black with polished jaws.

The Ventilation of Mines.

Mine ventilation and sanitation is a subject of great importance to miners the world over. Coal mines become so dangerous, usually, where the ventilation is poor, from the accumulation of explosive gases, that much attention has been given this subject in that class of mines. Metal mines, being to a great extent free from firedamp, the subject of ventilation is one often given less attention than it should have, owing partly to the lack of appreciation of the existing conditions, and partly to the desire to entail no unnecessary expense—the matter of providing better ventilating facilities being too often considered as "unnecessary expense"—so long as men can be persuaded or hired to work in the vitiated atmosphere. In Western Australia the condition in some of the mines was considered sufficiently bad to warrant official investigation. In accordance with this idea a Royal Commission, consisting of trained mining men, physicians, chemists and others, whose experience and business interests fitted them for such duty, was appointed. The result of their exhaustive investigation has been published in a good sized volume entitled "Report of the Royal Commission on the Ventilation and Sanitation of Mines," issued by the Department of Mines at Perth, W. A., and from which the following has been abstracted:

Methods of Ventilation in Use.—With very few exceptions, the ventilation of the mines of this State is entirely "natural," that is, due to differences of temperature and height of the air columns in different parts of the workings. Whether this method is satisfactory or not depends on a great variety of circumstances, giving excellent results in many cases, while others are very indifferent. When there are two separate shafts to a mine, or two main airways by which a circulation of the air may be maintained from the surface into the deepest parts of the mine and thence back by a different route to the surface, the ventilation is generally pretty good, but if the airways are small and much obstructed it may be very poor. We are sorry to find this condition anything but an uncommon one in our mines. The airways ought at all times to be of such size as to easily carry the necessary quantity of air. Where there is only one opening into the workings, the shaft serving both as upcast and downcast, it is almost impossible to preserve good ventilation, as the air short-circuits from one compartment into the others at every possible opportunity, and very little of it goes through the workings. A very notable instance of this was quoted in the Victorian Mines Ventilation Bonus Board's final report, who found that of 31,348 cubic feet of air entering the shaft per minute, only 2377 feet per minute went through the workings. This phase of the question presents itself in most of the deeper mines at their lower levels, before the levels have been connected with those above them by rises and winzes, and in such workings the ventilation was often found by us to be far from satisfactory. Such places require that some mechanical means of ventilation should be employed, but outside of these there appears to be, as yet, no very great difficulty experienced in practice in ventilating all portions of even our deepest metalliferous mines by natural ventilation, so long as the levels are connected with one another right through to surface by winzes and other openings. The ventilation is, however, subject to the great drawback to all natural ventilation, viz., that the direction of the air currents is often very variable, depending on the balance of the air columns in different parts of the mine, which is much affected by the wetness of the places and by the heat generated by working and by oxidation of minerals, as well as by differences of temperature on the surface. It frequently happens, therefore, that the air currents flow one way one day and in the opposite direction on another day. Even main shafts are found at times to be upcasts and at other times downcasts. In this State this variation is all the more likely to be common because, as a rule, owing to the flatness of the country, there is little difference in the relative altitude of the tops of the upcast and downcast shafts. It necessarily follows that there must be periods of longer or shorter duration between the reversals of the air current, during which there is no circulation, and in certain parts of the mines this condition may continue long enough to be serious. There may also be local air currents circulating through certain parts of mines, the same air passing round and round without being renewed. Dr. Haldane and Messrs. Martin and Thomas, in their "Report on the Health of Cornish Miners," describe a striking instance of this in the Levant mine, the warm air from the deeper levels rising upwards through passes and worked out ground into cool wet parts of the mine and there becoming so cooled as to pass down the main shaft again instead of rising to the surface. The same air was therefore traveling round and round without leaving the mine, and necessarily became very impure. We met with a very similar case in Bayley's mine at Coolgardie in the three lowest levels.

In mines ventilated solely by natural ventilation, it is evident that the variations of the conditions causing movement of the air must be attended with corresponding variations in the velocity of the current, and, consequently, in the quantity of air passing through and the degree of purity which can be maintained. Measurements of the quantities of air entering or leaving or passing any given point in a mine, or tests of purity, therefore becomes of little use in determining the adequacy of the ventilation unless they are repeated at very frequent intervals and the results are averaged.

The want of constancy in direction and volume of the currents of air in a mine ventilated solely by natural ventilation is therefore a grave difficulty in the way of practically establishing whether or not it is adequately ventilated. Great attention should accordingly be given to regulating the air currents, so as to keep them as much as possible always moving in the same direction, and to avoid vitiated air being carried back into the workings. The methods of "splitting" the air, which have proved so advantageous in colliery ventilation, are unfortunately but little used in our metalliferous mines, but could be adopted with a great deal of benefit. Among our witnesses there were several who were well acquainted with both coal and gold mines, and their testimony was almost unanimous that collieries are, as a rule, far better ventilated than metalliferous mines, both in this State and elsewhere, although really much more difficult to deal with on account of the greater extent of their workings, their usually flat dip, and the noxious gases which emanate from the coal and the strata enclosing it, and which demand a strong and continuous current of air to sweep them away and render them harmless. They mostly agreed, also, that there was little practical difficulty in adapting the methods used in colliery ventilation to metalliferous mines, the principles being the same in both cases, and that it was the disregard of elementary principles in the latter that rendered their ventilation on the whole so much inferior to that found in good colliery practice.

The coal mines at Collie were the only mines in the State examined by us in which any serious attempt was made to replace natural ventilation by more efficient and controllable means. The Collie Proprietary Co. use a large exhaust fan, and have a ventilating furnace as a stand-by, while the Cardiff mine relied on a furnace. The fan employed gives a very poor efficiency, and could be substituted by one of the better modern types with great advantage. The furnace does fair work, but has all the drawbacks incidental to this method of ventilation, and would be preferably replaced by a good modern fan. The question of the mechanical ventilation of collieries has been so thoroughly discussed in standard text books and in numberless papers in technical journals that we have not thought it necessary to devote more than this passing reference to it, especially as the collieries are at present only small in this State, and their ventilation is a very simple problem from the colliery engineer's point of view. The main question to be decided in each case would be the choice of a suitable fan, and so many considerations of finance, business reasons and adaptation of existing plant come into this that it would be out of place for us to say what type ought to be selected.

In only a very few of the metalliferous mines examined by us has there been any serious attempt at producing ventilation by mechanical means or furnace draught. The largest installation was that at the Associated Northern mine at Kalgoorlie, where an iron pipe 12 inches in diameter leads from the foot of the roasting furnace chimney down the main shaft to the bottom level, 1050 feet, where branch pipes, 8 inches in diameter, are taken from it into the various crosscuts and drives. The chimney draught causes a fairly strong exhaust of air from the deep levels, drawing out the smoke after firing with considerable success. The draught, however, is not strong enough to clear the ends of smoke so quickly as is required, and a certain proportion of it hangs back in the level. The device caused very considerable improvement in the ventilation of the 1050-foot level, and the manager, Mr. Roberts, in his evidence, expressed himself well satisfied that its introduction had resulted in economy of working, the men losing far less time in waiting for the smoke to clear than previously. Considerable difficulty was, however, experienced with the pipes collapsing after heavy blasting, and being broken down if brought too near to the face. Stouter tubing was evidently required. In the Murchison Associated mine at Day Dawn, since the commission's visit, a small Sturtevant fan has been installed. In the other mines the mechanical appliances seen were confined to a few small water jets and compressed air injectors used for ventilating rises and dead ends. In Bayley's mine a small fan was used, driven by a compressed air engine made from an old rock drill, a device more noticeable for ingenuity than for economical use of the compressed air. Very little care had been taken with any of these appliances to secure the maximum useful effect. In the great majority of the mines the use of compressed air from the mains supplying the rock drills is looked to as the only means of blowing out the smoke from explosions, and the exhaust air from the working of the drills is relied on to keep the atmosphere fit for men to breathe. This method, therefore, calls for more extended consideration.

(To be continued.)

Gold Dredging in California.

The importance of the gold dredging industry in California is increasing with each year. From a very small beginning made nearly forty years ago, it has grown and expanded, particularly within the past decade, until it has become one of the most notable factors in the gold production of that State. This industry has been made the subject of official inquiry by the State Mining Bureau of California, and the latest bulletin issued by that institution is devoted to the subject of gold dredging as practiced in all its phases in California and from which the following is taken:

HISTORY.—It is popularly supposed that mining for gold with dredgers is an industry which has grown up within the past decade and that it was a success almost from the beginning. This is not true There are bleaching skeletons of dredgers scattered over California and New Zealand, some of which were built nearly half a century ago. There was a dredger near Oroville, on the Feather river, in the '50s. It is over forty years since dredging was first tried in New Zealand. Spasmodic attempts were made in this direction on the Pacific coast and in New Zealand from that time on. These efforts, futile as they were, so far as giving dividends to shareholders go, were of great value to the miner and mining engineer of to-day. These failures were their warnings.

As a result, this class of mining, if properly directed, is now as safe as any, provided that skilled investigators direct the investment and use of capital, and see that it is only invested where conditions permit of successful work.

Any one investigating the processes at Oroville or Folsom, or in New Zealand, where conditions are known by actual practice, will find that the difficulties have been largely overcome, because the conditions have been studied by skilled men at large expense and met with appliances fitted for the local needs, not only as to the digging of the ground, but also as to the saving of the gold.

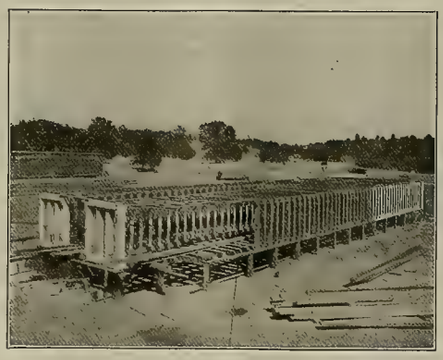
But under other conditions, in other districts, the dredgers so successful at Oroville or Folsom or in New Zealand would be failures as to some of their parts. To explain: At Oroville the gravel is loose, free from clay. There are no large boulders, the bedrock is soft, the gold is fine and it easily amalgamates. Along the streams in the mountains of California the boulders are larger, the bedrock harder, and in places in Idaho and Colorado the gold will not amalgamate owing to the presence of arsenic. Then there are many other conditions that differ in other places. Some of these difficulties may be overcome by slight changes, either in the digging part of the dredger or in the gold-saving appliances; but some of them, such as hard bedrock, in cases are fatal to successful dredging.

The conditions bearing on the cost of operation are such that each tract of ground becomes a problem in itself, and any attempt to use the costs obtained under one set of conditions, on which to predicate those which would hold under another, without a thorough knowledge of the various elements which enter into the problem, will lead to large discrepancies between the results predicted and those actually obtained, with a consequent possible failure of the enterprise.

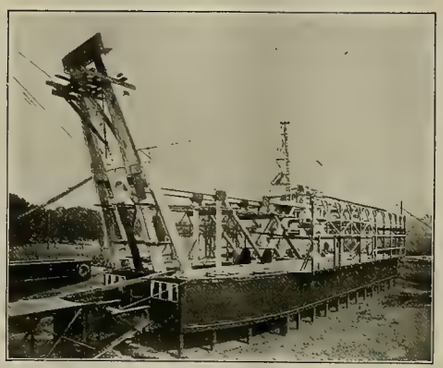
There have been built in California many dredgers that have failed and become total losses. Yet to-day, with all the data at hand for any careful investigator, there should be little excuse for failure. The varying conditions that exist where dredging is being done at Oroville, Folsom, in Trinity county, in Idaho, Montana, Colorado, British Columbia, the Klondike, Alaska and New Zealand, both as to the digging of the gravel and the saving of the gold, give the miner the actual experience necessary for him to come to conclusions under most circumstances.

The single-bucket or spoon dredger was evolved in New Zealand in the early '60s and was worked entirely by hand. A steam single-bucket dredger was built in 1870. About 1880 bucket-and ladder dredgers were introduced. These were nearly all worked with power furnished by current wheels. The first steam chain bucket dredgers of the present type were introduced about 1882. One dredger of this class, built about that time, was successfully worked for sixteen years. On account of the success of a dredger in 1889 on a branch of the Molyneux river, some twenty were built at an average cost of $17,500, but were failures, owing mainly to the fact that the ground was not suitable for dredging and the management bad. Many of these dredgers were floated down to the Molyneux river and under new ownership were made successful. Then a number of suction dredgers were built, but proved complete failures. Since then the endless-chain bucket dredger, similar to those used in California, has held the field. In New Zealand at the end of 1902 there were 201 dredgers working, 52 standing, 23 building, 14 under removal and 2 wrecked—a total of 292.

The first successful endless-chain bucket dredger in the United States was built in 1894 at Grasshopper creek, in Montana. Many attempts to dredge had been made on the Pacific coast, but it was not until 1897 that a dredger of the present type was built in California. In the summer of 1895 W. P. Hammon and Warren Treat, who were interested in horticulture near Oroville, were working some gravels for gold on property now owned by the Feather River Exploration Co. Mr. Treat had made a pit about 100 feet square down to bedrock, using a centrifugal pump to keep the water out, and hauling the gravel in wagons out to small sluice boxes, where it was washed. The gravel was handled several times by manual labor, and in spite of the heavy cost for labor and pumping water, there was a profit. Mr. Hammon had another pit, but on approaching bedrock found that the great amount of water coming in would make mining at a profit difficult.



Framework of a New Dredger in the Pit.



Hull Completed and the Gantries Up.

Ladder Frame and Rollers.

Placing Close-Connected Buckets in Position.

The attention of the writer was called to these cases and he visited the property, and, after consulting with Mr. Hammon as to the best process for working, suggested hydraulic elevators; but it was found on investigation that the distance necessary to convey water, and the large amount of water in the ground itself to be handled, would make this impracticable. At that time little was known of dredging in California. However, some of the land had been purchased through Mr. Hammon and A. F. Jones. A few months later Thomas Couch and F. T. Sutherland, from Montana, were in San Francisco, Cal., looking for mining properties. To them was suggested the Feather river gravels, and there they went, and, with Mr. Hammon, after prospecting for about a year, purchased 1000 acres, which are now being worked by five dredgers.

While they were prospecting this ground, R. H. Postlethwaite, a New Zealand engineer, who had come to California to look over the dredging field, had constructed by the Risdon Iron Works a 3¼-cubic foot bucket dredger to be used near Smartsville, on the Yuba river. While the dredger itself was satisfactory, the conditions did not permit of final success in working.

The first dredger at Oroville, built for the Feather River Exploration Co., began work March 1, 1898. It was designed by Mr. Postlethwaite and built by the Risdon Iron Works. This dredger is still being successfully operated; it has been strengthened, however, in parts.

Steam was used at first, but now all the dredgers in the Sacramento valley districts are worked by electric power. During the first two years of successful dredging at Oroville with endless-chain bucket dredgers, a number of attempts were made to dredge with suction and other styles of dredgers; but all these, with the exception of one steam shovel dredger, were failures.

AREA OF DREDGE GRAVEL.—The following table will show in a general way the acreage of gravel under consideration for dredging. It is probable that these figures will in many cases be increased and other districts opened:

District	Acreage.	Average Value per Cubic Yard, in Cents.
Oroville	7,500	17
Yuba River	5,000	25 to 30
Bear River	1,000	18 to 30
Folsom	5,000	15 to 25
Calaveras	350	16 to 22
Stanislaus	1,200	15 to 30
Trinity	1,000	... .
Shasta	1,500	.....
Siskiyou	1,000	.....
Plumas	1,500	.....
Total	25,050	

In Stanislaus county considerable prospecting has been done and about 1200 acres have been proved to contain values sufficient to warrant dredging.

In Shasta county drilling is being done on Cottonwood creek and on land opposite Redding, on the Sacramento river, and on Clear creek.

In El Dorado county some land on the South Fork of the American river, near Coloma, is being considered, but not yet reported proved.

In all these districts, and at other points in the Sacramento watershed especially, there are considerable areas of dredge gravel, most of which have been more or less examined, but not proved to be of sufficient value to work at the present cost.

The best dredge authorities claim that by proving good grade of pay in some of this outlying ground and reducing working costs, at least 25,000 acres will in time be added to the fields which it is already decided to dredge in the Sacramento valley.

In this connection experiments are being made with a view to working by a process similar to the present dredging system, but at a much lower cost. Those interested do not care to give out any data at present.

It may seem a simple thing to those who know to say that there is a great diversity in methods of gravel mining caused by varying conditions of the deposits, and that the method in vogue in one case may mean failure in another. Yet the want of this knowledge has been the cause of immense waste of capital. There have been large sums of money lost in trying to hydraulic drifting ground. Attempts have been made to use hydraulic elevators to work dredging ground where there was an excess of water to be handled. Dredgers have been built to work ground that could be worked only by means of hydraulic elevators. There are many thousands of acres of gravel, mostly lacustrine deposits, in California and other States and Territories on the Pacific coast and in Alaska that is free from water and should be worked with steam shovels, which people are now exploiting with a view to working with dredgers. In other words, they are proposing to make a condition—by flooding the ground with water—that means an unnecessary cost. A study of the conditions existing will lead to conclusions as to the methods to be adopted, and in this way only can economic success be made.

The different kinds of gravel mining, it may be said, are:

First.—Ordinary hydraulic mining, requiring water

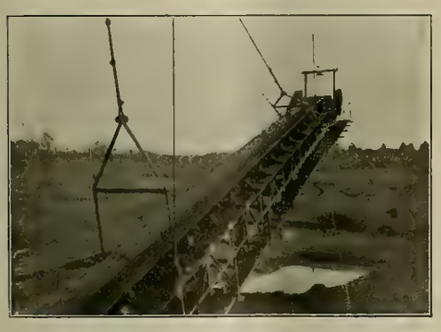
under pressure and a good dump, with gravel easily removable.

Second.—There are the drift mines in layers of gravel deposits overcapped with lava or other material of such great depth that only underground or drift mining is possible.

Third.—There are the bars along the rivers, based on hard bedrock, that must be worked with hydraulic elevators for want of dumping facilities, and which

The Tailings Stacker Drive.

The Stacker Without the Belt.



A Tailings Stacker With Belt Conveyor.

can not be worked with dredgers because the bedrock is hard. Yet in these cases it must be understood that even hydraulic elevators are of no use if there is an excess of water.

Fourth.—There is the gravel with an excess of water, with soft bedrock, that can only be worked with dredgers.

It would be futile to hydraulic the lava-capped divides in Placer and other counties in California; yet this has been attempted. They must be drifted.

It would be impossible to make an economic success of the use of hydraulic elevators at Oroville or Folsom on account of the excess of water in the gravel; yet this has been attempted.

In some mountainous districts of California dredgers have been tried and proved failures, because the bedrock was too hard to dig and the gold could not be lifted.

Then there are cases where the excess of water prevents the use of hydraulic elevators, and the hardness of the bedrock and the consequent conditions that usually follow prevent the use of dredgers. Yet inventions not now known may be made to work these gravels at a profit.

Then, again, there are large tracts of gravel, usually of lacustrine deposit, in the Sierras, not deep and not overcapped with lava, that afford good opportunity for the use of steam shovels.

Geology.—While dredge mining is being conducted under conditions apparently satisfactory to those engaged in the industry in the Sacramento valley districts of Oroville, Yuba, Folsom and Calaveras and on the Bear river, there is an interesting geological feature worthy of more than a passing thought, and that is that all this dredging is being done on what may be considered a superficial layer of gravel, underlaid by a stratum of volcanic mud and sand, the deposition of which, of course, antedated the deposition of this gravel.

The gold-bearing veins existed and were eroded for a great period of time, antedating the volcanic activity which is such a prominent feature of the Sierra Nevadas, and the ancient rivers deposited their gold-bearing debris upon the original bedrock, both within the limits of their rims and upon the floor of the great interior valley—the present valley of the Sacramento river—which at that time was a vast fresh water lake.

Subsequently the volcanic activity resulted in many instances in filling the old gold-bearing rivers to the brim with a vast quantity of volcanic material, now recognized in the mud, tufa and breccia overlying the ancient river channels, and, as a matter of course, this volcanic material was carried out into the estuaries, extending even into the lake itself to a considerable distance, and covering the previously deposited gold-bearing gravel. The subsequent uplift of the whole Sierra Nevada system has resulted in the exposure of these lake beds along the eastern edge of the Sacramento valley.

The subsequent erosion of modern streams, cutting through the original ancient river channels and often into the underlying bedrock, with its complex system of gold-bearing veins, resulted in the formation of a later bed of gravel, which rests upon the volcanic sands and mud of the lake.

Doubtless this process has been repeated a number of times, and this point could be determined by drilling or by sinking shafts. But it is clearly evident that the present dredging is not in deposits of gravel resting on the true bedrock—the slates and schists which form the adjacent foothills—but in later and, quite likely, less valuable gravel.

In many ancient river channels there are sometimes two or three gold-bearing strata, called by the miners "leads," and the stratum of gravel on the bedrock is usually the richest, while the upper strata are relatively of less value in gold per cubic yard. There are, however, instances contrary to this, where one of the upper strata is of more value; but this is due to local conditions, probably generally to the erosion of other pre-existing beds of gravel. Why this principle should not be proved true in this lake is well worth considering.

Similar conditions have been found to exist in the Cariboo country in British Columbia and in some of the mountain districts of California outside of the Sacramento valley region.

The discovery, however, of good value in these lower strata might not lead to satisfactory economic results, because the expense of handling large bodies of water that might be encountered would handicap any venture in that direction.

In connection with the question of reclaiming these dredging grounds, it may be mentioned that James H. Leggett, owner of dredgers at Oroville, has begun some experiments by planting eucalyptus and olive trees on the rock piles, with a few spadefuls of earth at the root of each tree, and they are thriving.

(To be continued.)

Iron Mistaken for Copper.

T. Lane Carter, who has lately returned to Johannesburg from a long trip north of the Zambesi, says Page's London Weekly, has been giving his fellow members of the Chemical, Metallurgical, and Mining Society of South Africa some useful hints on the subject of copper prospecting. He remarks that in the first place the prospector should know copper when he sees it, and not mistake something else for copper. A case is mentioned where a number of claims were staked out along a bold outcrop, beacons, placed, etc., but when the prospect was sampled and assayed the colored material turned out to be a silicate of iron, without a trace of copper. As to the amount of chemicals and appliances to be taken on an expedition, everything depends on circumstances. If one is to leave assay office and laboratories entirely behind and wishes to assay the copper samples at each prospect then it is necessary to have a complete outfit. This outfit must indeed be complete, for a whole expedition might be hampered by leaving behind an important chemical.

Mistakes similar to those above referred to were made in the early days in California along the Mother Lode. From El Dorado county on the north, to Mariposa county on the south, numerous copper claims were taken up and considerable work done on what was supposed to be copper ores, the bright green micaceous mineral, afterward named mariposite, being mistaken by the early prospectors for malachite, the green carbonate of copper. Glauconite and a number of other iron silicates have a green color and may be mistaken for copper ores, though containing no trace of that metal. Most copper ores are readily soluble in nitric acid, making a green solution, which the addition of an excess of ammonia will cause to turn blue. Often it at first causes a brown precipitate—iron—but by adding more ammonia (which must be done with care, to avoid spurting due to violent chemical reactions), the solution if containing copper will turn blue, the intensity of the color being greater or less according to the amount of copper present.

Electric Drill Tests.

Under date of August 8 A. W. Sayles, N. Y. representative The Mine & Smelter Supply Co. of Denver, Colo., furnishes some data, showing results of a recent test made in that city by the New York Edison Co. of the Durkee electric drill. The data are embodied in the following letter:

The Mine & Smelter Supply Co., 42 Broadway, New York City.—Gentlemen: We beg to advise you that we have made two thorough tests of the Durkee electric rock drill supplied by you to this company, and have found it most satisfactory. Both tests were made on excavation work and have shown the drill to be most efficient and economical. The first was conducted at our 121st Street station and resulted as follows:

Date.	Number of Holes Drilled.	Depth in Inches.	Number Working Hours Per Day.	Time Lost Blasting and Muck.	Number Feet Drilled Per Day.	K.W. Hours Consumed.	Cost Per Day.
				H. M.			
April 21	12	58	6¼	0 30	58	8.7	$0 87

	(6) (36)		8	1 5	49	7.4	0 74
March 13	16	36	8	0 45	48	6.3	0.63

On April 21st and 27th and May 1st, 2nd, 4th and 5th the heavy rain prevented a full day's work. The average number of feet drilled per day was over 60 feet at an average cost of 1.5 cent per foot.

The second test was made at the northeast corner of 12th Street and 4th Avenue, and confirmed the figures contained in the previous test.

The following will show the work done from day to day:

Date.	Number of Holes Drilled.	Depth in Inches.	Number Working Hours Per Day.	Number Feet Drilled Per Day.	K.W. Hours Consumed.	K.W. Hours Per Foot.	Cost Per Foot.	Cost Per Day.
							Cts.	
July 5	17	48	8	68	8 09	131	1.31	$ .89
July 6	17	48	8	68	8.35	.123	1.23	835
July 7	18	48	8	72	8 06	.120	1.20	86
July 8	3	48	1 5	12	.05	.04	.40	.05
July 10	11	48	6	44	4.05	.92	.92	.405
July 11	20	36	8	60	6 45	.107	1.07	.645

On July 8th and 10th the work was stopped on account of rain. At both 121st and 12th Streets, the rock is of mica schist and muds easily, but your drill, on account of its stroke, escaped this entirely.

Thanking you for your kindness in supplying us with the drill, and congratulating you on its most satisfactory showing. Yours very truly,

(Signed) Arthur Williams,
General Inspector.

THE PROSPECTOR.

The rock samples from Goldfield, Nev., are determined as follows: No. 9, a bleached rhyolite. No. 10, gray, compact limestone No. 11 is a coarse aplite, or micaless granite. No. 12 is crystalline limestone. No. 13 is also aplite, similar to 11, but containing pink orthoclase. No. 14 is apparently a silicified rhyolite. The quartz blebs are plainly seen in this rock. No. 15, not yet determined. No. 16 is an altered and silicified eruptive rock, the original character of which it is difficult to determine in the small hand specimen. An examination of the mass from which it came might give further information on that point. No. 17 is a white, bleached rhyolite, very similar to No. 9. No. 18 is a fragmental rhyolitic rock composed of an agglomerate of pumice, quartz blebs, shattered feldspar crystals and grains of hard, firm, reddish brown rhyolite. The "sedimentary deposit beneath" may also be of volcanic material. No. 19 is a dense siliceous rock, probably an altered sedimentary. No. 20 is a flint-like rhyolite, in which a few crystals of pyrite appear. No. 21 is trachyte, in which there is considerable sanadine (glassy feldspar). No. 22 is rhyolite, similar to Nos. 9 and 17, but is stained with mineral oxides. No. 23 is not petrified wood, but a stringy, pumice-like lava, containing still numerous crystals of quartz. This stringy structure and the generally wavy appearance of the rock is due to some movement of the magma during the process of cooling, much the same as molasses candy is stretched out in the stage intermediate between the liquid and solid condition. No. 24 is a granular eruptive rock, somewhat altered. It is also apparently rhyolite.

Placer Mining in Alaska.

NUMBER II.

Horse Scraping into Sluice Boxes. — Ground which can be worked by men shoveling into sluices can, under certain conditions, be worked by horse scraping, and at one-third the expense. The most important governing condition is the degree of looseness in the gravel and in the underlying auriferous bedrock. Two horses or mules hauling a scraper, with driver, will cost from $17 to $23 a day, and in the ordinary small gravel of the Alaska placers, with soft schist bedrock, the team will scrape into the boxes from 30 to 40 cubic yards of gravel a day over a distance of 75 feet. On Penelope creek, in Seward Peninsula, it was said that the team would handle as much as ten men could shovel, the cost per cubic yard being 30 cents.

One common breaking plow with a team of horses suffices to break up enough ground for four scrapers. The method requires an inclined platform built up to a height of 10 to 15 feet above the bedrock, over the head box of the sluice. A rectangular opening in this platform serves as a chute to the dump box. Generally the horses travel in an elliptical track, passing the end of the tail box and scraping the tailings from it, then entering the pit, scraping up the pay, and afterwards delivering it to the sluice. In Seward Peninsula the cost of this method can be brought as low as 25 cents per cubic yard, and in no part of the interior will it exceed 50 cents, exclusive of top stripping.

Steam Scrapers.—The ordinary scrapers used in steam scraping operations on tailings in the Klondike have a capacity of from ⅓ to ½ cubic yard, operated by double drum, two-cylinder hoist; 16-inch drums, 25 to 30 H. P. capacity, handling on an average 250 cubic yards of loose material in twenty-four hours, at an average expense of 49 cents per cubic yard. The manipulations of the scraper, considered as a unit of the plant, take three or four men on shift—a fireman, a hoistman, and either one or two men to fill, guide and dump the scraper. The form and rigging up of the scraper, with the system of sheaves, pulling and drawback cables, is shown in Figs. 2 and 3. In practice the scrapers drag the material from the pit to the dump, a distance measured horizontally from 100 to 300 feet and vertically from 20 to 50 feet. The scrapers are not always provided with teeth like the one shown in the figure, but this is advisable. A rigid bale should never be used, as flat stones catch between it and the body of the scraper. The plants average $3500 in cost.

On Walker Fork, Forty-Mile district, Alaska, a body of gravel 60 feet in width and 5 feet in depth, with little or no stripping, was mined. According to information, the gravel was only partially free, and little or no stripping was required. As a rule the scraper was found to clean the schist bedrock satisfactorily. The scraper used had a capacity of one-fifth cubic yard, being an ordinary horse scraper rigged for steam with pulling and drawback cables. A 6 H. P. hoist operated the scraper, giving a capacity of 100 cubic yards in twenty-four hours. The 10 H. P. boiler also furnished steam to operate the bucket elevator which lifted the gravel to the sluice from the hopper, to which it was dumped by the scraper. A conservative estimate places the cost of handling gravel with rig, three men being employed and one-half cord of wood burned in ten hours, at 40 cents per cubic yard.

The plant contains the elements of a device which, it is not unlikely, may be applied to the working of the wide, shallow creek deposits of Seward Peninsula, or of such creeks of the interior as Mammoth, in the Birch Creek district, or lower Pedro, in the Fairbanks district. If circumstances warranted, the sheave anchor (a rock-filled crib) could be made more easily movable by mounting it on a truck running on track, it being made fast by cable and deadman when occasion might require. The bucket elevator employed is not recommended, as the use of such contrivances for handling gravel, unless they are specially and expensively constructed — as on large dredges — is condemned by experience. In place of this, the scraper should be dragged entirely to the point of final discharge to the sluice on an inclined platform. The operation will necessitate the building of a more elevated sluice or washing plant, surmounted by a hopper, the gravel being fed from this in order that the feed may be as nearly continuous as possible. Assuming that the elevation of the head box of the sluice shown in the illustration is 12 feet above the surface of the ground, the scraper could be dragged to double this elevation at a cost not exceeding 10% above that necessary to haul it up to the 12-foot elevation.

In general, it may be said that this method is applicable to operations on schist bedrock, but is entirely impracticable on limestone or other hard bedrock. This is also true of the steam shovel and dredging methods. Grant that bedrock conditions are suitable, and consider a solidly frozen deposit of characteristic small gravel with muck and moss overburden, 150 feet width of pay and 7 feet in total depth from grass roots to bottom of pay. After the moss is plowed up, the 3 feet depth of muck can be ground-sluiced off in the ordinary manner at an expense of, say, 15 cents per cubic yard. The ground sluicing should be done at the earliest possible moment in the open season, or preferably late in the fall. The operator now has to deal with a stripped block of frozen gravel and auriferous bedrock 4 feet in depth, carrying pay, or the material which it is desired to sluice. A vertical bank of this material cannot be attacked by any mechanical appliance yet devised, but if left uncovered for six weeks it will thaw to bedrock. The operator, however, wishes to take advantage of the continual thawing of the surface by the sun, and to do this he must attack not a

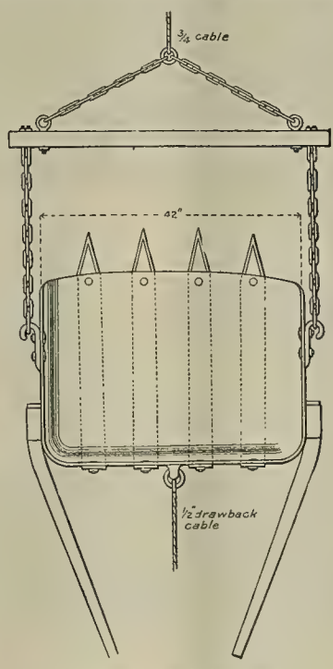

Fig. 2—Toothed Scraper.

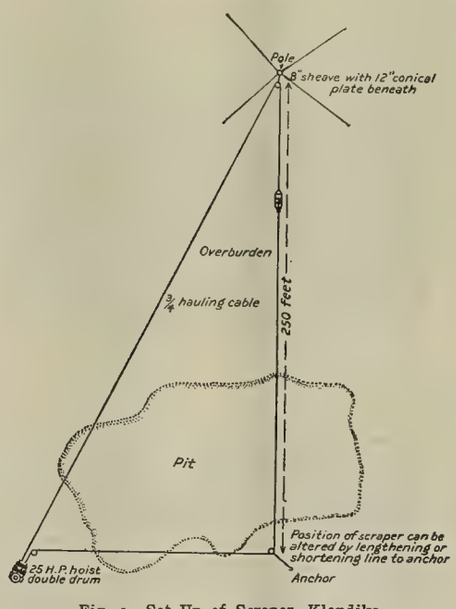

Fig. 3—Set Up of Scraper, Klondike.

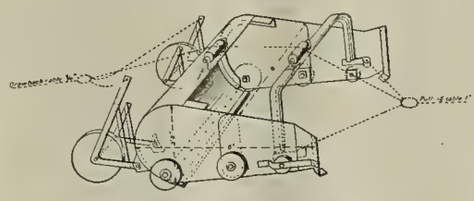

Fig. 4—Bottomless Steam Scraper.

vertical but a horizontal surface. The rate of natural thawing varies from 6 inches to 1 foot a week. The scraper, armed with teeth rigged so as to make a series of transverse cuts, say for 300 feet lengthwise of the channel, will attack the ground, scraping off the thawed material better than any other mechanical appliance.

The sluice boxes or washing plant, built to a height of 25 feet above the surface of the ground, can now be approached by a broad incline platform, or if desired the scraper may dump to cars, which convey the material by gravity to an isolated and conveniently situated washing plant. The system adopted will depend on the magnitude of the operations. In only very exceptional cases should the expense of handling, after the material is once dumped from the scraper, be allowed to exceed 5 cents to the cubic yard.

The plant above suggested implies the use of a scraper of large capacity and should handle the gravel at a total cost, including depreciation charge and added cost of stripping, not to exceed 40 cents per cubic yard in Alaska, provided that 700 cubic yards of gravel a day are sent to the sluice. In order to accomplish this a scraper, preferably of the bottomless, self-dumping type, of 6 yards theoretical capacity, should be used. It will be found that actually 3½ yards will be delivered each time by such a scraper. The operations will require a 60 H. P. boiler and double-drum hoist, and the services of seven men on a shift. The total running expense of the plant should not exceed $150 a day of twenty-four hours.

The double-drum hoist operating the scraper will have a position on the side of the sluice opposite that of the cut, and can be mounted on skids so that it can be easily moved by means of a sheave and deadman if necessary. The sheave through which the drawback cable runs may be anchored to a weighted car running on 200 feet of track laid parallel with the cut on the side opposite that occupied by the sluice and hoist. If it is desired to keep the drawback cable out of the way it may pass through two sheaves, one anchored to traveling anchor and one to deadman, the cables thus forming a triangular arrangement, two of whose angles will vary as the car is moved to cover various parts of the ground. The car may be moved as often as desired, and thus one furrow after another may be made by the scraper over a triangular area as the ground thaws. By means of a rearrangement of the sheaves it is found that nearly all of the ground can be covered. A plant erected for the Klamath River G. M. Co.* is provided with two 1½-yard scrapers, which travel back and forth alternately, both cables acting as pulley and drawback cables. Two sheaves are used on the side of the excavation opposite to the washing plant. "These sheaves are attached to a spreader which keeps them spaced a given distance apart, and to each end of the spreader is attached a tackle which runs back at an angle to deadmen, to which they are securely anchored."

The type of bottomless scraper shown in Fig. 4 was seen in successful operation stripping loam at a reservoir excavation near Portland, Oregon. It has a theoretical capacity of 6 yards, and actually handles over half this amount. Measurements of a spoil bank showed that in seven ten-hour days, stripping to 4 feet in depth, 400 cubic yards per shift had been handled. The scraper was making furrows over 300 feet in length. A 60 H. P. boiler was used, but only one cord of wood at $2 per cord was burned. The double-drum hoist was provided with 10x12-inch cylinders and was gearded 6 to 1. Four men, a winchman, fireman, and two scraper men were employed, at $2.50 a day. It was said that under these conditions the operations cost 5 cents per cubic yard. It was estimated that in a haul of from 150 to 200 feet the scraper would deliver loam to the spoil heap at the rate of 2 cubic yards per minute.

The above suggestions regarding the use of self-dumping scrapers in northern placer mining will doubtless be looked on with considerable skepticism. No direct application of the method has, so far as known, been made in Alaska. The form of plant outlined is inexpensive as compared with many already installed in Alaska, having a capacity not exceeding 700 cubic yards. The sum of $10,000 should be ample to install an entire scraper and washing plant in Seward Peninsula. Even should some form of steam scraping be found applicable to the wider shallow deposits, the installation of elaborate cableways, traveling towers, and the like, is not advisable, as in most cases their cost would be prohibitory.

*Yeatman, J. A., Automatic excavator for placer mining: Min. and Sci. Press, Dec. 17, 1904.

(TO BE CONTINUED.)

Potassium Cyanide in the Blast Furnace.

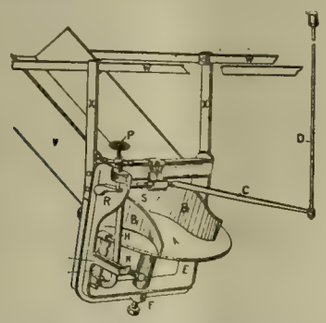
The production of an inferior material in the puddling furnace when the best pig iron is used has been attributed to the action of nitrogen in the blast furnace. H. Braune, in Oest. Zeit., 1905 LIII, p. 153, considers that it is mainly due to the formation of potassium cyanide and similar products which owe their origin to the use of basic charges, together with high pressure and temperature of the air blast. Iron and free nitrogen do not combine directly at any temperature, but if the nitrogen is combined, as in potassium cyanide, combination with the iron can take place very easily, the reaction being accelerated by rising temperature. Iron oxide is also not attacked by free nitrogen, but it readily reacts with potassium cyanide as follows: $KCN + FeO = Fe + KCNO$. The potassium cyanate takes up oxygen, forming carbonate, which rises to the furnace mouth and is found in the flues and downcomers. If bisilicate charges be used, and the iron be blown with the blast heated to 150° to 200° C., only traces of nitrogen are found in the resulting product. To remove nitrogen from steel attempts have been made to use titanium thermite.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 1, 1905.

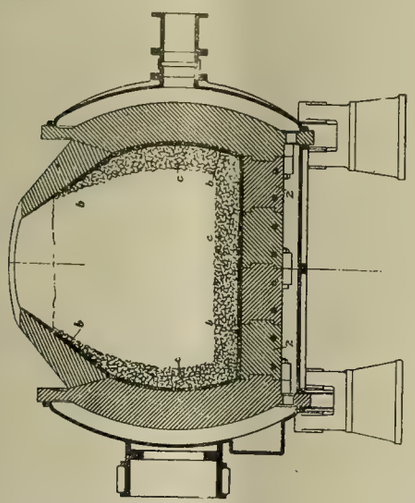
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE FEEDER.—No. 795,923; M. Nelson, Kalgoorlie, Western Australia, Australia.



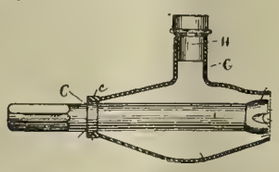
Ore feeder comprising ore chute, rotatively mounted receiving table located at discharge end of chute, guide wings for table secured to discharge end of chute and projecting outwardly therefrom abreast of table, means for intermittently rotating table, and means for adjusting table toward and away from wings.

CONVERTER LINING.—No 796,170; C. M. Allen, Lolo, Mont.



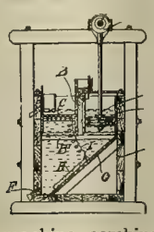
Copper converter having air tuyeres, and distributed unpacked adherent interior lining of material containing silica.

ATTACHMENT FOR ROCK DRILLS. — No. 796,327; M. Hardsocg, Ottumwa, Iowa.



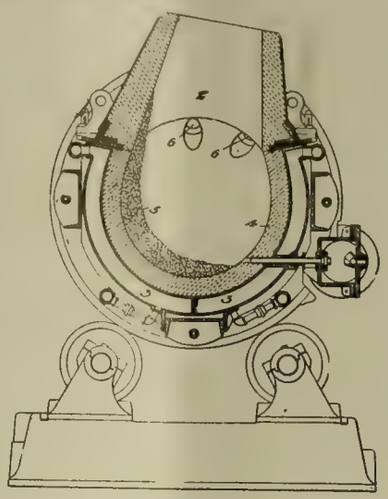
In combination with bit, protective sheath having walls of flexible material and having enlarged body portion terminating at one end in mouth having edges adapted to abut against substance being acted upon, body terminating at opposite end in opening surrounded by elastic flange adapted to impinge against shank of bit for holding sheath in fixed contact with bit and allowing body to be laterally expanded with the forward movement of the bit, and an exhaust pipe for exhausting air from interior of sheath.

ORE DRESSING MACHINE.—No. 796,172; H. S. Anderson and J. W. Bennie, Clifton, Ariz.



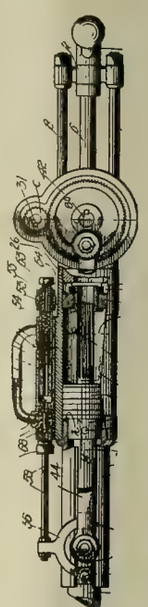
In ore dressing machine, combination of containing vessel, metallic screen therein forming electrode, electrolytic liquid containing metallic salt derived from ore treated and submerging screen, means for causing liquid to pass and repass through screen, second electrode in vessel submerged in liquid and subject to current thereof, and means for maintaining screen in electronegative condition relatively to second electrode.

METHOD OF CONVERTING MATTE.—No. 796,282; R Baggaley, Pittsburg, Pa.



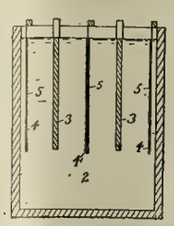
Method of converting matte, which consists in distributing lining of unpacked siliceous material over working area of interior of converter, cintering same in place, introducing matte into converter, and blowing air therethrough.

ROCK DRILL.—No. 796,228; E. R Langford, Los Angeles, Cal.



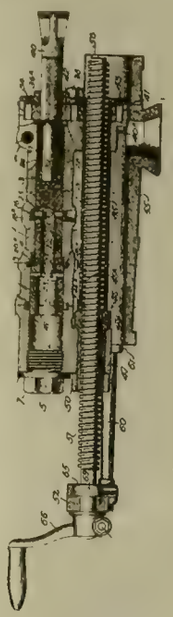
Cylinder, piston therein, piston rod connected thereto, slotted extension from forward end of cylinder, sleeve on piston rod having wing which plays in slot of extension, head on rear of cylinder, head having cupped portion and plurality of journals, shaft in one journal, gear on shaft and within cupped portion, driving shaft in other journal, pinion on driving shaft within cupped portion meshing with gear, pitman, crank pin through one end of pitman screwed to gear, and pin through other end of pitman screwed to wing of sleeve.

ELECTROLYTICALLY REFINING SILVER.—No. 795,887; A. G. Betts, Troy, N. Y.



Process of electrolytically refining silver which consists in subjecting silver alloy anode to electric current in electrolyte containing free, non-oxidizing, strong acid forming readily soluble silver salt, and silver salt of acid, and electrolytically depositing silver on suitable cathode.

DRILL BIT ROTATING MECHANISM FOR ROCK DRILLING ENGINES.—No. 796,081; J. G. Leyner, Denver, Colo.

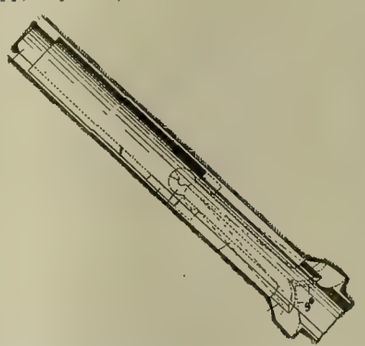


A rock drill, comprising cylinder having piston hammer and revoluble drill chuck, support on which cylinder is slidably mounted, feed screw in engagement with cylinder and support, and means whereby rotation of screw effects rotation of chuck.

CRUSHING ROLLS.—No. 796,244; R. Pick, Buffalo, N. Y.

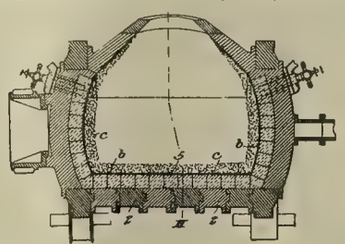
Crushing roll having peripheral ribs arranged at angle with relation to roll axis, each of ribs having plurality of transverse V-shaped grooves.

DRILL HOLE ENLARGING DEVICE.—No. 796,165; T. M. Topp, Raymond, Cal.



Device for enlarging and chambering drill holes, including shanks having outwardly turned bits at one end, segmental heads at opposite end about which they are turnable, heads having divergent adjacent faces and interlocking point and socket central of curvature of heads, shank having transversely disposed segmental channel within which heads fit and are turnable, and fixed wedge shaped block whereby bits are forcibly separated at each stroke or impulse.

COPPER CONVERTER.—No. 796,174; R. Baggaley, Pittsburg, Pa , and C. M. Allen, Lolo, Mont.



Copper converter having compacted silica lining and interior lining of unpacked material containing ore.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

Dredging operations are in progress on the upper Yukon. Moncrieff Segber's dredger has been put on Bonanza creek. Another big dredger at the mouth of Bear creek is handling thousands of tons of gravel. With favorable conditions it handles 2000 cubic yards of dirt daily, though much of the ground is frozen. This dredger digs 35 feet below the surface of the water, throws the tailings 22 feet high and stacks them 90 feet back of the machine. The hulls of the steamers Ora and Nora are being used to form the twin hull of the dredger which J. J. Rutledge is building for Forty-Mile river. He will dredge the stream for 6 miles from the mouth up. A dredger which the Williams Co. is taking down the Yukon from White Horse will work a big concession in the Klondike basin, between the Klondike City bridge and Ogilvie bridge. —— It is reported from Fairbanks that 250 men have gone from there to the new Kantishna gold strike, 150 miles in the interior from Fairbanks. Steamers run within 75 miles of the diggings. Pans on Eureka creek yield from $5 to $10. A townsite has been started.

ARIZONA.

Cochise County.

The Tombstone Con. M. Co. expects to increase the capacity of the present Girard mill to forty stamps and put up a cyanide plant. The ore tests made have proven satisfactory and the plans for the treatment of the large ore reserves have been decided upon. The company owns the Grand Central mill on the river, and twenty stamps are to be brought to Tombstone and added to the Girard mill. The third large pump at the 800-foot level is expected to be in operation by September 1. At the Emerald, Lucky Cuss, Tranquility and Silver Thread, work continues with the same force.

Gila County.

J. C. Erman, in charge of operations at the Keystone Copper Co.'s mines, west of Globe, has been experimenting with electrolytic copper precipitation at the mine and has produced several sheets of copper. The ore in solution is allowed to flow upon large copper plates on which precipitation takes place and the sheets are stripped from the plates as soon as this precipitation ceases to be complete. The ore carries chrysocolla with occasional carbonates and a little chalcopyrite in an 18-inch fissure vein traversing granite. Considerable ore has been shipped to the Old Dominion smelter.

W. A. Thompson and Rayson have taken a bond on the Barnett gold mine at Bloody Tanks, near Globe. Machinery for treating the ores is to be put in.——Frank Thompson of Globe has bonded some claims on Pinto creek to A. W. Sydnor, who is associated with A. West & Bro. in operating the property. —— A. C. Sheldon of Phœnix, after examining the Iron Cap property, east of Globe, has interested capital in Salem and Beverly, Mass., to carry out the company's plans. Active work will be commenced within a month.

Graham County.

(Special Correspondence.)—Superintendent Rosecrans of the Standard Consolidated C. Co. at Clifton recently closed down the tramway for ten days while the towers were strengthened. In the deepest workings a 5-foot vein of ore has been uncovered which may average 10% copper. The first shipment is now ready from the San Jose mines. The company was formed as a merger of the Coronado M. Co., Standard copper mines and the San Jose mines, on Chase creek, 5 miles north of Clifton. The ore is carried from the mine to the Coronado Railroad by a 3200-foot Leschen aerial tram, with a drop of 800 feet, which carries the ore at a cost of 5 cents per ton, as compared with $2 per ton when shipped by burros.

Clifton, Aug. 14.

B. M. Crawford, manager of the Crawford G. M. Co., operating near Clifton, states that work is being pushed on three levels of the mine, and that two new winzes are being sunk. Development work has also been commenced on the Lefave property, recently purchased by the company. Good milling ore is being developed in all of the workings.

The Detroit Copper M. Co. will put in a new electric motor to handle the air compressor and hoist at the Old Yankee. The air compressor which is running the drills in that mine and which is on the third level will be brought to the surface. Gas has been used largely for power. A Loomis generator, with capacity for making gas to supply 1000 H. P. from New Mexico bituminous coal, has given satisfaction, averaging 1 H. P. hour from 1.5 to 1.75 pound of coal, making a saving of 30% in fuel cost. Gas is used for power throughout the mine and plant, except in the locomotives and hoists.

Mohave County.

(Special Correspondence).—At the West Gold Road mine at Acme Superintendent J. D. Spargo is putting up a blacksmith shop and office, and, for the present, is developing the mine with a 15 H. P. Union gas engine.

Acme, Aug. 16.

O. F. Kuencer, superintendent of the German-American mines, near Vivian, reports that sinking is in progress on the Thirty-fifth Parallel, Treadwell and Pioneer of the German-American group, but that the volume of water shows no appreciable increase. The shafts range in depth from 225 to 250 feet, and in all of them the ore bodies are improving in width and value. It is proposed to sink the shafts to a depth of 400 feet, and if water in quantity is not developed it is probable that a supply will be obtained from the Colorado river.

Yuma County.

It is reported that the Colonial M. Co. have sunk a 180-foot double-compartment shaft on their quicksilver mine at Cinnabar, 14 miles from Ehrenberg. Manager L. S. Judd has been purchasing material for a reduction plant.

Yavapai County.

The Richinbar M. Co. will put in a 50-ton cyanide plant at their works at Richinbar.

The Planet & Saturn mine, near Congress, has been sold to H. J. Beemer by W. A. Clark.

CALIFORNIA.

According to E. W. Parker, in a recent report of the U. S. Geological Survey, the total production of coal in California in 1904 was 78,888 short tons, valued at $375,581. All of the coal produced in both California and Oregon is lignitic in character. There are in California a number of rather widely separated lignite areas, the chief of which are the Mount Diablo and Corral Hollow fields. The principal production is from the counties of Alameda and Contra Costa, while small amounts are mined in Kern, Monterey, Riverside and Siskiyou counties. The Corral Hollow field is in Alameda county and Mount Diablo in Contra Costa county. Two other areas which have produced small amounts of coal are the Ione field, in Amador county, and a small area near Elsinore, in Riverside county. In a number of other counties coal or lignite beds have been prospected to a greater or less extent, and Butte, Del Norte, Orange, Fresno, Monterey, San Diego and other counties have produced small amounts in the past. Some recent prospecting has been done in Fresno, Mendocino, Placer, Orange and Trinity counties, but little encouragement is held out for any extensive development. The greatly increased production and increasing use of crude petroleum as a fuel has not encouraged the development of the coal mining industry in California in the last few years. It is believed, however, that the recent demonstrations made at the Geological Survey coal testing plant at St. Louis, Mo., and which have shown the excellent producer gas-making qualities of lignite, will create a demand for this class of fuel and stimulate production in this State. In 1903 there were produced 104,673 short tons, valued at $294,736. This indicates a decrease in quantity of 25,785 short tons in 1904 and an increase in value of $80,845. This increase in value, in spite of the smaller production, was due to the fact that all of the product of the Tesla mine, the largest producer in the State, was shipped to Stockton and manufactured into briquettes. The value is given for the briquetted fuel. The plant at Stockton is of new construction and has a capacity of 125 tons per day of ten hours. The briquettes produced are round, convex lenses, or "boulets," weighing from six to eight ounces. Asphaltic pitch from California crude petroleum is used as a binder, the reduction from the crude petroleum to pitch being done at the plant. The briquettes are compressed under very heavy pressure and each one is dropped 25 feet to a storage bin shortly after leaving the press. So far as the writer is informed, this is the only coal briquetting plant in practical operation in the United States up to the close of 1904. There are, however, a number of experimental plants in operation, and several plants are under construction or in contemplation. One of these is at Oakland and another at Pittsburg, both in California. The decrease of production in California in 1904 was due in most part to the mines at Pittsburg being shut down, awaiting the completion of the briquetting plant.

Butte County.

The Sky High mine, on Gravel range, near Powelton, has been sold by George Broden and Gordon Graham for $30,000.

Calaveras County.

S. W. Newell has contracted with Manager G. McM. Ross of the Union Copper M. Co. at Copperopolis to haul the supplies for the mines and the output of the smelters with a traction engine on the roads between Milton or a station on the Sierra Railway, as may be determined later.

The San Andreas Blue Gravel mine has been unwatered and sinking and drifting started.

Lake County.

(Special Correspondence). — The Baker mine, near Lower Lake, is now in operation under Manager Dack, and is producing about thirty-four flasks monthly. Until recently this mine was not a commercial success, but under the new management is said to be paying well.

Lower Lake, Aug. 14.

El Dorado County.

W. F. Russell of St. Louis and T. Arbuckle of Cincinnati have been inspecting the Argonaut mine, near Greenwood, and if satisfactory arrangements can be made, it is reported that they will put up a 60-stamp mill and work the mine. The mine is owned by John Smith of Greenwood and C. M. Jordan of Placerville. —— At the Live Oak mine, Reservoir Hill, near Placerville, the rich body of gravel holds good.—— At the Last Chance mine, Nashville district, some very rich ore is being taken out. Sinking is being done with fifteen men.——At the Havilah mine, near Nashville, a strong pay ledge is being developed and seventy-five men are employed.

Humboldt County.

In the Orleans Bar section the hydraulic claims are all shut down, on account of scarcity of water, and very little will be done there in mining until the rainy season commences, about November. The past season in that section has been very good for the miners, who have taken out as much gold as the average season.——Quigley Bros. & Hegler have finished a 280-foot dam at the Lew Doggett place on Klamath river, near Riverside, 12 miles from Arcata, and have pumped out the water, so as to commence sinking to bedrock in the river.——A. C. Brokaw of the Advance mine is ready to put in a new 10-stamp quartz mill at the mouth of China gulch. He will commence building a wagon road, also digging a ditch and building flume from Russian creek.——The Medina M. Co. at Oro Fino are working the Johnson mine. The work on the Gardner ledge is proceeding, and good ore is being taken out. The mill is closed down for lack of water.

Mono County.

The Noonday mine and the South End mill at Bodie have stopped work.

Nevada County.

The 10-stamp mill at the Culbertson mine, near Graniteville, is running, it having been leased by John Keller and son Albert, who are opening up their claim, which adjoins the Culbertson.

Under the direction of Superintendent W. M. Wilson, the Omega M. Co. has commenced building a new restraining dam in the canyon below the mine, near Washington. It is expected to have the dam ready for inspection before winter sets in, as the company desire to make a good run during the rainy season. The barrier will be larger than the one which was blown up last winter and it will be constructed of concrete.

W. S. May has completed overhauling the Pennsylvania mill, near Grass Valley, and will resume crushing ore from the mine.

Shasta County.

The Bully Hill C. Co. has twenty miners employed at the old Winthrop mine at Copper City. Day and night shifts are at work. Ore was recently found in the Upper Winthrop, which is worked through an upper tunnel.

Sierra County.

The Mabel mine, American hill, near Alleghany, is being worked with twenty men under the management of A. J. McCoy. This mine is owned by J. W. Morrell & Co.

Siskiyou County.

The Mono M. Co. at Punch creek, near Humbug, is putting in a 12-stamp outfit, also concentrators and cyanide vats to work the tailings and sulphurets. The mill is to be operated by electricity from the Siskiyou Power Co.——The Eliza quartz mine on north fork of Humbug, near Yreka, is to be opened by Patterson of Portland. At the end of the old tunnel a 7-foot ledge has been developed. The new owners intend putting up a 10-stamp steam mill, having figured that it is cheaper than to extend electric wiring 3 miles from the Mono mine.

COLORADO.

Clear Creek County.

Ore from the Santiago mine, in the East Argentine district, is being crushed in the Clear Creek mill, which was recently purchased by W. Rogers, general manager of the Hazelton-Santiago Con. M. Co. The mill has been overhauled and will handle from 50 to 100 tons of ore during each twenty-four hours. The treatment consists of first crushing the ore, then running it through jigs, after which it is reground and run over the tables. The plant is so arranged that the tailings will be dumped back of the mill, where they will remain until the cyanide tanks, which have been ordered, have been put in. The concentrating material which is being delivered at the mill is being taken from the dumps of tunnel No. 3. The smelting material is being taken from the development work now going on in tunnel No. 3. F. A. Maxwell, lessee of the Colorado Central, has made arrangements for the treatment of ore which will be taken from the upper dumps on that property. David Kennedy, owner of the Centennial, will also send ore to mill for treatment.——The Bi-Metallic tunnel on McClellan mountain, near Georgetown, is in 725 feet. It is understood that the Bi-Metallic G. & S. M. Co. will put in machinery. J. W. Boughton of Philadelphia, Pa., president of the company, recently visited the property and made arrangements for increased work.——At the Mineral Chief on Democrat mountain, near Georgetown, Manager W. C. Hood is working through the Moline tunnel.——Henry Seifried of Georgetown has purchased a one-half interest in the McClellan mine on Leavenworth mountain.——The Kirtley mine on Leavenworth mountain, near Georgetown, is to be developed. Jefferson Raynolds of Las Vegas, New Mexico, has bought a one-fifth interest in the property from the estate of C. A. Martine and preparations are under way for development through the Equator tunnel. A drift is to be run west 700 feet for the purpose of cutting under the old ore shoot.——The Independent M. Co., operating the West Griffith property on Griffith mountain has made connection with the East Griffith workings.

Near Empire, the Charter Raton Co. are developing claims on Breckenridge mountain, and have driven crosscut tunnels in 150 feet from the portal.——The Marshall Russell tunnel is still making good progress since the washing out of their water power dam and the bursting of their air compressor. They have put in a new air compressor. J. Bridge has a 500-foot contract on the tunnel, which enters the mountain near Empire Station.

Gilpin County.

Machinery is being put in by the Victoria-Phœnix G. M. Co., on Mineral hill, north of Boulder park in the Phœnix district, a new road having been built up Buckeye mountain.——At the East Boston shaft of the East Boston M. Co. drifting is being carried on in the 600-foot level, while in the 500-foot level both stoping and drifting is being carried on. The east and west levels of the Rialto are being extended and an upraise is being made to the 500-foot level both for opening up ore and improving ventilation. S. Hoskin is manager and W. Job is foreman.——It is reported that the owners of the Russell property in Russell district have decided to resume operations with F. Paxton as manager. A heavier plant of machinery is planned for the main shaft workings of the group.——The Perrin shaft in Russell district is down 200 feet.——The Esculapian G. M. Co. is developing the Star of the West, in the Lake and Russell districts, under the management of W. J. Blake of Denver. Operations are being carried on through the Gibson shaft, which has been retimbered and the levels cleaned out. The main shaft on the Gibson is down 225 feet, and after doing some development work in the 200-foot workings, Manager Blake decided that additional depth was needed in order to open up the ore bodies for production, and sinking operations have been commenced to go down another 100 feet.——The Raven group, in Russell and Lake districts, is being worked by the Pearce Gold M. Co., with H. G. Pearce of Denver as

manager A gasoline hoist, formerly on the Hamlet mine in Gregory district, is being put in and an addition is being made to the shaft building. The main shaft is down 200 feet and will be sunk another lift of 100 feet. F. Hardy is in charge of work.

The recent damage to the hoist of the East Notaway mine in Russell district, southeast of Central City, has been repaired and hoisting resumed by Superintendent T. G. Martin. —— A. Kapella has charge of work at the Powers mine in lower Russell district. Stoping is being done in the 200-foot east level and an upraise is being made from this level to the old workings of the Powers shaft. F. Murphy is manager for the owners.——Hoisting water from the Saratoga shaft was commenced with the water standing a little below the 450-foot level. Griffith & Co. will hoist the water to the 550-foot point, after which Owen & Co. are expected to take the water at least 200 feet deeper, so that work can be carried on in some of the lower levels. Griffith & Co. of Russell Gulch have been working the upper levels.

Gunnison County.

At the Midland mine, on Beaver creek, near Vulcan, the crosscut tunnel, which is to go in 1300 feet, has been run 100 feet. A new mill with amalgamation and cyanide equipment is planned. T. J. Thompson of Gunnison is interested.

The Ashland M. Co., operating the Carter tunnel under the management of C. M. Carter, near Ohio City, has cut what is believed to be the same vein that was lately cut by the Raymond tunnel. A larger compressor and drills have been ordered.

Lake County.

It is announced that the Yak tunnel will be extended from the Ibex mines into the Big Evans section to drain the mines in that quarter. The drive will be about 5000 feet. It is now over 2 miles long. It would strike underneath No. 2 shaft of the Resurrection, 30 feet deeper than the present depth of that shaft, which is 950 feet. The whole of the Big Evans basin would be drained and the mines will have no further trouble from water.—— Another find of molybdenite has been opened by Simons & Moorhead in their claims at Twin Lakes. Arrangements are being made with the Colorado Tungsten Co. to handle all of the output, and shipments will start in a few days.

Park County.

At a recent meeting of the Colorado-Minnesota M. Co., engineers recommended that the company erect a concentrating plant of a capacity of fifty tons per day, and this was ordered done by a majority vote. M. D. Sterrett of Colorado Springs was chosen president; F. O. Sterrett of Colorado Springs, secretary and treasurer; W. L. Boatright, assistant secretary. The company owns thirteen claims in the Tarryall district.

San Juan County.

(Special Correspondence).—On the Animas river, 6 miles north from Silverton, the Hamlet M. & M. Co. are operating their 50-ton mill, which consists of crushers, rolls, jigs and concentrating tables. A canvas plant is being added to the mill. This company are the owners of ten claims on Galena mountain, and so far the mine is developed by four tunnels on the vein, all of which are producing ore. Another tunnel is being driven 300 feet below the present workings. The present workings are 1000 feet higher, vertically, than the top of the mill. As the mine is developed and tonnage increased the capacity of the mill will be increased. The ore carries copper, zinc and some lead. A jigback tramway delivers the ore from the mine to the mill. A carload of concentrates is shipped every two and a half days. Geo. Robin is manager of mine and Chas. Gray, mill superintendent.

Howardsville, Aug. 12.

(Special Correspondence).—T. H. Kane, general manager of the Hercules Con. M. Co., has been blocking out ore preparatory to starting up his 100-ton concentrating mill. New machinery will be put in and the mill capacity will be increased to 150 tons.——About 1½ miles down Cement creek from the Gold King mill the Stony Pass M. Co. are driving a tunnel to tap several veins which are known to exist in Prospect basin. The tunnel is in 1420 feet and A. W. Hall, president of the company, thinks that the first large vein will be cut in the next 100 feet. They have already cut several small veins in the tunnel. The electric drill which was purchased some time ago will soon be started up. It is understood an electric hoist will be put in. J. W. Doolan is superintendent.

Silverton, Aug. 12.

(Special Correspondence).—The 80-stamp mill of the Gold King Co. is handling 300 tons of ore per day. After catching a good percentage of the values on the copper plates it passes over Frue vanners and from there to the new mill, which consists of four tube mills and thirty-six Wilfley slimers. It is said the tailings after passing through the new mill and which are sampled automatically contain but a trace of gold. The De Laval steam turbines, which were installed by the Denver Engineering Works, are doing excellent work at this mill.

Gladstone, Aug. 12.

The Ruby Basin M. & T. Co. is shipping 50% lead concentrates from the south Mineral creek mill, near Silverton. The best ore comes from a shaft now down to a depth of 25 feet on the December vein. This shaft will be put down to a depth of 100 feet, when levels will be run and a pumping station put in. The crosscut tunnel on the Ruby property is in the meantime to be continued from its present 1400-foot point on to the Tornado lode. T. J. Hurley has charge.

San Miguel County.

At Ophir Loop Superintendent Ladd has twenty men at work on the Butler vein of the Ophir Con. M. Co. and in the 10-stamp mill.——Chas. De Witt is to develop the Merrimac claims in the Ophir district.——The Gold King Basin M. & M. Co. is making preliminary tests of the ore carried by the principal vein of its claims in Gold King basin, preparatory to making improvements. Two mill runs, one from the upper tunnel and the other from the lower, are being taken out and will be treated at the Gold King 40-stamp mill. Chas. De Witt is foreman.

Summit County.

S. F. Stoughton has bonded and leased the Carrie mine and 10-stamp mill, near Frisco, for the King Solomon M. Co. The mill is being overhauled and refitted and the 900-foot tunnel has been cleared out.

The Carbonate and Little Tommy groups on Mount Baldy, near Breckenridge, have been bought by the Buckeye M. Co. and are being worked under the superintendency of G. E. Moon.——The Lucky mill, near Breckenridge, has been overhauled and started up by the Beaver Creek M. Co., on lead ore.

The new 100-ton capacity concentration mill of the Old Union M. & M. Co., on Mineral Hill near Breckenridge, was started, after some alteration in the machinery. The mill is believed to now be in good shape to handle the second-class ore from the tunnel which the company is driving to connect with the two shafts and the levels therefrom.——G. C. Smith is working the Copper King and Copper Queen ledges in Muggins gulch, near Breckenridge.

Teller County.

Geo. Kimball of Idaho Springs and Geo. Leyner of Denver have purchased the Gillett cyanide mill at Cripple Creek and have teams and men working over the dump of the Gillett reduction works. —— The lessees operating the lower shaft of the Agnes Co., on Beacon hill, Cripple Creek, have opened a new body of ore and are building ore bins to hold the rock.——The eighty men who were laid off for two weeks at the Portland property on account of repairs being made at the mill in Colorado City have been put back to work. The ore body recently opened is holding out well. It was found at a depth of 1350 feet in virgin territory.——At Cripple Creek the Moose Co. has finished timbering the Trilby workings and operations have been suspended until after the meeting of the company.——The K. C. Mutual M. Co., working a portion of the Jerry Johnson, have cut a strong vein in driving north in the 100-foot level. As soon as the surface water sinks sufficiently to permit sinking the shaft will be continued down to a depth of 250 feet.——The Stratton-Cripple Creek M. & D. Co. has appointed G. L. Keener lease manager of the company.

IDAHO.

Boise County.

L. and A. Unternaher of Boise are opening up a rich quartz property on Hay Fork creek, 16 miles east of Idaho City. It is reported that they intend putting in a mill this fall.

Owyhee County.

Work has been commenced on the Banner M. Co.'s property near Silver City, with Robert May in charge. ——At the Addie mill, near Silver City, the pans and settlers from the Scales & Smith amalgamating mill at Wagontown are being put in. Stoping is being done in the upraise in the mine.

Shoshone County.

Shipping ore is being opened up in the lower workings of the Stewart mine near Government gulch, near Wardner. H. F. Samuels is the principal stockholder in the Stewart and has charge.

The Sonora Co., which owns claims above Burke, has decided to resume work in an old shaft that has been idle since the 80's. The Powhattan M. Co. owning claims in Big creek, near Wallace, expect to resume operations with two shifts. O. M. Gaut is managing director.——The new double compartment shaft which the Sister Co. is sinking on its property in Canyon creek, east of Wallace, is down 135 feet, and is being sunk at the rate of 4 feet a day. Three eight-hour shifts are employed. The intention is to put it down 250 feet and then crosscut to the ledge. An electric hoist is to be put in.——At the Pittsburg Co's properties on Nine Mile the mill is shut down for lack of sufficient water for power purposes. The air pipe line has been completed to the workings in No. 3 tunnel level, and two drills are working double shifts on east and west drifts from both crosscuts on the level. Nothing will be done on the No. 4 level for at least a month. The compressor has not sufficient capacity to run machines on both levels at once. The company is overhauling and repairing the mill and increasing its capacity by the addition of a new set of rolls and four 6-foot vanners. It is also to be equipped with electric power, and as soon as this is done the mill will resume, as there is at all times an ample supply of water for milling purposes.

Washington County.

The Iron Springs M. Co. at Iron Springs will convert the Rankin mill into a cyanide plant and will put in a 50-ton crushing mill to determine the best process of ore reduction.

MONTANA.

Granite County.

Sherr & Looney are working the Nonpareil, near Princeton, with a small force. The shaft, which is down 400 feet, is being retimbered and the hoist is being overhauled. —— At the Albion, above Princeton, Wagoner and associates are developing. They expect to put in a mill to treat the ores from the property.

The Lennstrende-Buck syndicate is putting a mill on its properties near Garnet.

Jefferson County.

A. B. Keith is working claims near Clancy.——High-grade ore is being shipped from the Muskegon mine in Lump gulch, south of Helena.——Martin Mulvahill of Helena has secured control of the Nob Hill properties in Lump gulch, and will begin development at once, sinking 100 feet from the 130-foot level.

At the Gold Hill, 2 miles southeast of Parrot, Manager Van Zandt has replaced the surface equipment recently burned and has retimbered the shaft. Sinking has been started from the 200-foot level and will be continued to the 400-foot.——Fred Davis, Frank Pruitt and Tincture are taking ore from the Colorado mine, 6 miles from Whitehall, at a depth of 200 feet.

Lewis and Clarke County.

The East Helena smelter is getting a larger ore supply than for years before, most of which comes from properties in the immediate district. The Whitlach-Union at Unionville, south of Helena, being worked by the Whitlach M. Co., has put in a new electric plant to run its hoists, pumps and compressors. The shaft has been sunk to the 500 level and a crosscut is being run to cut the main vein at that depth, and will be run 170 feet to strike the vein.——The Brooklyn Bridge Co., owning properties 1 mile south of the Whitlach, has decided to abandon the old incline shaft and sink a 2-compartment working shaft.——The Sunrise mine in the same vicinity has been bonded to H. L. Frank of Butte, and is being developed under the direction of Miles Cavanaugh.—— J. A. Rowland, who has been developing properties in the Big Blackfoot in the Lincoln district, has purchased a mill which will be put up at once.——The Red Bird Co. is working men on their Red Bird and Copper Hill properties, near Helena. Another 100 feet will be sunk on the Copper Hill from the 250 level and a crosscut is being run to the vein from the 350-foot level on the Red Bird.

Silver Bow County.

The Berlin Co., north of Butte, has sunk its shaft 200 feet and it is likely that no crosscutting will be done until 500 feet is reached. The shaft is a double-compartment and is being timbered as sinking progresses. The capacity of the United Copper and Heinze smelter has recently been increased. There are now two converters in operation and three furnaces. With the ore of the Rarus, Corra, Minnie Healey, Lexington and the waste dump of the Belmont, together with the custom ore, the plant has been busy.

MICHIGAN.

Houghton County.

(Special Correspondence). — Three years ago it was thought that the ultimate productive capacity of the Lake Superior mines would be about 200,000,000 pounds per annum. This figure was exceeded in 1904 and will be exceeded in 1905, barring accidents. The properties of the district may be divided into five classes, according to production: The old producing mines; the new producing mines; the developing mines; the active prospects, and the inactive mines and prospects. Practically all of the old mines should at least hold their own in output for the next five years. The Calumet & Hecla has work under way which should result in increasing its production to 100,000,000 pounds per annum within the next few years. The Tamarack has been a slowly declining property for the past six years. The Quincy should show an increase. The northern end of the mine is showing improvement at depth, and the prospects of the property are brighter than for many years past. The Osceola Consolidated may be included in the list of old properties, and should show an increase. Atlantic should hold its own, as should Wolverine. On the whole it will be found that the old mines of the district show possibilities for increased production. Among the new mines there are excellent prospects of increased output. The South Range mines, controlled by the Copper Range Consolidated Co , the Baltic, Trimountain and Champion, will make more than 40,000,000 pounds of fine copper this year. On the north range the Mohawk, which is now making 10,000,000 pounds per year, is to be given increased capacity. The Michigan is likely to double present production, and the Adventure gives promise of also doubling its output. Of the developing mines the Allouez and Ahmeek should each be making 10,000,000 pounds or better within five years. Both are producing in a small way at present, carrying drift stopes which afford a limited tonnage of stamp rock for the mills. Among the prospects there are enough properties of promise to guarantee that from the number several good producers will be secured. The Globe tract, south of the Champion, is under option to the Copper Range Co. The overburden is very heavy and difficult of penetration, but the Copper Range Co. has funds to overcome unfavorable features of the early stages of development. Between the Globe and the Winona mines is the Erie - Ontario prospect, on which steady work has been performed. The Miskwabik has a promising property. Among the developments of the next five years should be the opening of a mine on Section 16 of the Atlantic Co.

Houghton, Aug. 14.

The Victoria has started to put in the permanent hoisting engine and is building the shaft rock house. The work on the three final cylindrical 5-foot shafts for the hydraulic compressor has progressed to a depth of 130 feet in each shaft, leaving 200 feet to sink in each of the shafts. The stamp head, the bed plates, anvil blocks, mortar block, mortar grate casing and the heavy frame legs have been put in position. The 5000-foot tram road from the mine to the mill is graded.

Keweenaw County.

(Special Correspondence). — In Keweenaw county there is activity in the southern end, at the Allouez, Ahmeek and Mohawk properties. The southern end of Keweenaw county is a continuation of the Calumet district, from which it is distant but a few miles, with continuous producing mines from the Osceola to the Mohawk at present. Farther north the Keweenaw Copper Co. has eight old mines, and will explore its property. The Calumet & Hecla Co. has bought Keweenaw county mineral lands during the present year. The Fitzgerald interests control the Arnold, Ashbed, Humboldt and Meadow properties.

Houghton, Aug. 14.

MISSOURI.

The United States Geological Survey has in press a report by H. F. Bain and E. O. Ulrich on the copper deposits of Missouri. Copper is now mined and smelted, near Sullivan, and copper deposits at other points in the State are attracting attention. Attempts to mine sulphide and carbonate copper ore have been made in Missouri since 1837, and at different times copper furnaces have been operated in Shannon, Ste. Genevieve and Crawford counties, while a matte, which carries also nickel and cobalt, has been steadily produced at Mine

La Motte. Copper is found commercially only in the southern part of Missouri, within the region broadly known as the Ozark uplift. This is an elliptical, warped plateau which has a major northeast-southwest axis about 300 miles long, and reaches its topographic culmination at Cedar Gap, west of the copper-bearing territory. In this region iron, lead, zinc, barite and manganese, as well as copper, are mined. The ores show a preference for certain stratigraphic horizons, and, being bedded, may be prospected with ease and economy. The common association of sulphides with specular iron of the sandstone region points to the advisability of the investigation of the old iron pits. In Shannon county the most favorable localities are along the contact of porphyry and dolomite at points where the conglomerate beds at the base of the latter fill in shallow basins in the crystalline rocks. In the disseminated lead district of southeastern Missouri copper occurs in connection with the lead, and at a few points can be saved to advantage. The mines near Ste. Genevieve have not been worked for several years, but the building of the Illinois Southern Railway to within a few miles of them so changes the situation that they can probably now be worked with profit.

Jasper County.

The Nest Egg M. Co. has leased of the Newell-Morse Royalty Co. forty acres of the Wilson-Rinehart section, near Webb City. J. J. Wickham of Cleveland, Ohio, recently leased another forty acres of this same tract. In each of these two leases there is a contract for the lessees to build two big mills. They are each to put two drills to work at once to test the drill holes already put down.——J. P. Hart, G. W. McClure and J. Crabtree of Carterville have struck a fine prospect on their lease on the Aylor ground at Alba.——The Beacon Hill mine, on the Leonard land in the Chitwood district, is being worked again.

Newton County.

The Auburn M. Co., with a lease on the Muenning land, southwest of Spring City, have their shaft down 181 feet and will sink to the 200-foot level.

NEVADA.

A petition signed by several hundred mining men and prospectors operating in southern Nevada has been received by Surveyor General Kyle, asking that a complete survey be made by the Government of all the public lands in the southern part of the State. At present the greater part of Nye and Esmeralda counties has been surveyed only by townships, the section lines not being run. This makes the location and proper description of claims extremely difficult, and serious litigation is apt to result. Surveyor General Kyle has endorsed the petition and the matter will be taken up at once with the authorities at Washington. Recently the Government ordered the survey by townships of several hundred thousand acres of mineral lands in Nevada, but the scope of the work is not large, considering the enormous unsurveyed section in the State.

Elko County.

The stockholders of the Dexter-Tuscarora Con. M. Co., with properties at Tuscarora, have ratified giving a bond and lease of the property to J. H. Mayham of Denver. The bond provides that Mayham is to sink the shaft to the 500-foot point, which is 200 feet below the present lowest level.——The Dexter had a good showing, but when the sulphide ore zone was reached it was accompanied with such a great volume of water that the management could not get it under control.

Esmeralda County.

It is stated from Bullfrog that J. Y. McKane and associates, representing Charles Schwab, have purchased the interests of the Montgomery Mountain M. Co., taking in the Shoshone Polaris property on the northeast and the Montgomery Shoshone M. Co. property on the east. The Crystal M. Co., which is controlled by Schwab, is the purchaser.

It is reported that a 100-ton mill and cyanide plant is to be put up at the Jumbo mine at Goldfield.

Eureka County.

Zinc discoveries are reported in the Roberts mountains, at the head of Pine Creek valley, 50 miles south of Palisade, on the Southern Pacific Railroad, and 12 miles to the west of the Eureka & Palisade Railroad, a narrow-gauge line. The shipping station is Alpha. It is 40 miles north of Eureka. Fletcher & Jameson of Eureka, the discoverers, have shipped a carload of ore to Kansas.

Lyon County.

Herman Davis of the Nevada Reduction Works has purchased the Briggs mill and tailings deposit in Gold canyon. He has men tearing down the mill and cleaning up the site, and the tailings, of which there are about 4000 tons, will be hauled to Dayton for reduction.

Nye County.

The narrow gauge railroad to Tonopah has been changed to broad gauge and hereafter no transfer of ore shipments will be necessary.

NEW MEXICO.

Grant County.

The Hermosa Copper Co., near Central, has closed down the greater part of its properties on account of the restrictions imposed by the forest reserve regulations, the Central district being included in the Gila Forest Reserve. Superintendent J. W. Bible hopes to make arrangement for resuming work.——In the Granite Gap district the San Simon group of six claims, owned by the Mineral Hill M. Co.; the Granite Gap group of seven claims, owned by the United States & Mexico Dev. Co., and the Louise group of six claims, owned by the Southwestern M. Co., are all being worked under the direction of Superintendent S. C. Pratt of El Paso, Tex. The Granite Gap shaft has been sunk 1000 feet on the vein, or 600 feet vertically. The ores are shipped from Antelope on the El Paso & Southwestern Railway. A good wagon road of 11 miles has been built from the camp to the railroad.

Otero County.

The Altamont M. Co. is to commence work on its Cuprite property near Jarilla. The shaft, which is of two compartments, timbered and lined, is down 130 feet and is to be continued to the 250-foot station cut, when two laterals will be started for the ore body.

OREGON.

Baker County.

J. K. Romig, manager of the Virtue mine, near Baker City, has leased the property to W. L. Vinson, manager of the Emma mine. Vinson says he will put a large force at work to operate the mine, but has not indicated whether he will continue the deep sinking begun with the new triple-compartment shaft or continue work from the lower levels of the old shaft. The tailings dump on the mine has been leased by J. H. Davey & Son of Baker City, who have a cyanide plant on it.——Manager F. T. Kelly of the I. X. L. mine at Greenhorn says he has ordered a large amount of sinking machinery and proposes to resume work with a larger force. The main shaft is down to the 300 level.

Manager Pierre Humbert, of the Cornucopia mine at Cornucopia, has started shipping to the Sumpter smelter.

At the Eureka & Excelsior mine at Bourne, Superintendent Jas. E. Wyatt has put a Jeanesville duplex pump with a capacity of 400 gallons per minute on the 550 level which will enable sinking to the 900 level. The water power plant is being increased, to furnish power for an Ingersoll-Sergeant 8-drill compressor, and 1200 feet of 14-inch pipe has been laid to make a new high-pressure line with a fall of 460 feet, giving at the highest stage of water flow 590 H. P. During the lowest stage a minimum capacity of 155 H. P. is had from the low-pressure flume, which is 700 feet long, 3 feet wide and 2½ feet deep, carrying 150 inches of water with a fall of 260 feet. In addition to this, 525 feet of 20-inch pipe has been laid to utilize an extra flow of water in the early spring, which will give approximately 200 H. P. By these improvements sufficient power will be generated at all times of the year to furnish mine and mill with power for operation and air for ventilation, and will eliminate the burning of wood from March to August. Crosscutting to the vein on the 550 level is in progress and is expected to be reached in the next 60 feet, after which drifting will begin and the shaft extended to the 700 level, later to be extended to the 900 level. Drifting is in progress on the 400 level.

It is reported that the Curby copper claims on Snake river, near Homestead, has been sold to the same syndicate which purchased the McDougal property. —— At the Mayflower mine of this district the cyanide plant being put up is arranged to separate the slimes and sands and treat them in distinct tanks.

Jackson County.

A controlling interest in the Opp mine, near Jacksonville, has been sold to Albany, N. Y., parties through Foster & Gunnell of Grants Pass, represented by R. Murphy.

Josephine County.

Operation this summer at the Takilma smelter, 45 miles from Grants Pass, has been constant since the plant was blown in. The output of matte is twenty to twenty-three tons daily, the product carrying 30% copper and about $10 gold.

The Argo M. Co. of Bellingham, Wash., has started its new 5-stamp mill in the Galice district.

Because of the success of the pump at the power dam of the Golden Drift M. Co., operating hydraulic giants in the Dry Diggings, the company has begun enlarging the penstock and placing eight more turbines of 400 H. P. each. This will supply power for two more pumps the size of the one now operated, or will give water and pressure to a battery of six giants instead of two. The company is operating its giants continually.

The Greenback Co. has begun placing thirty additional stamps in its lower mill on Grave creek, near Greenback. The addition of these thirty stamps, together with the forty already at work and other equipment that will be placed, will give the Greenback a daily capacity of 200 tons.

The Oregon Belle's new 10-stamp mill has been started. ——A 5-stamp mill has just been placed on the Rogue River mine of Merlin district and a 5-stamp mill and equipment is being put up at the Gold Pick mine of Sucker creek, having been hauled by wagon to Holland.

Consolidation of the Almeda and Rand mining properties on lower Rogue river at Galice has been perfected, the new company to be known as the Almeda Consolidated Mines Co. There is 1300 feet of work on the Almeda. Arrangements have been made to put up a smelter of 100 tons capacity. O. M. Crouch, formerly president of the Almeda Co., has been named president of the consolidated company, J. F. Wickham vice-president and manager, R. C. Kinney secretary and treasurer and L. B. N. Simonds financial superintendent.—— The Homestake mine, near Woodville, is to be opened up. There is a 5-stamp mill at the mine, run by a gasoline engine, which is being replaced by electric motors for power from the Condor Water & Power Co. The concrete foundation for the transformer and two dynamos have been put in, and it is expected to have the transformers and motors in place within the next two weeks. Water for milling has been secured from a gulch near the mine, but in dry seasons this supply fails, and to overcome this difficulty a pump will be put in to take the water from Rogue river, a distance of 1600 feet.

SOUTH DAKOTA.

Custer County

Superintendent J. N. Wright intends enlarging the Extreme mill and adding a cyanide plant. The mine is 2 miles northwest of Custer.

Lawrence County

At Galena, J. D. Hardin is putting in a 180-stamp mill, a 3-mile railroad and a large hoisting plant. —— President R. L. Bailie of the Golden Crest M. Co. has made arrangements for resuming work at the company's mines, 3 miles from Galena. —— The shaft of the Dizzie mine, near Maitland, is being sunk by H. H. Francis. A new pump is to be put in.

Pennington County.

At the Gertie tin mine, near Hill City, Manager E. C. Johnson has secured the necessary brick, cement, etc., for a small reverberatory for smelting the tin concentrates he is getting from the 35-ton experimental mill. The ore, which is a granite of exceptionably coarse grains and containing considerable mica, is crushed by jaw crusher and steam stamp to 20 mesh. It is then run over 15-foot copper plates to recover the free gold. No trouble has been caused by the mica scaling. The pulp is then concentrated on Wilfley tables.——The Canton M. Co. will continue their shaft, northwest of Hill City, from the 135-foot to the 200-foot level.——A 5-stamp mill is being put up by the Gopher M. Co., near Hill City. A hoist is being put in and an aerial tram between mine and mill is expected to be running by fall.——At the Clara Belle mine, near Oreville, Frank Herbert has put in an air compressor and two machine drills. A new vertical shaft is to be sunk and a 10-stamp mill and cyanide plant to be put up.——A working shaft is to be sunk on the Mercedes mine, west of Rochford, by Superintendent James Cusick.

UTAH.

Beaver County.

In the Star district, near Milford, ore is being shipped from the Moscow mine by D. Ferguson and from the Marionette mine by J. Favey.

Juab County.

At the Carisa mine at Eureka, Manager H. S. Joseph reports three new stopes, two being within Spy ground, between the 600 and 700-foot levels, another on the 200. In addition to these the stope on the 150-foot level in the Carisa vein is giving good ore.——Work has been started on a raise for air connection with the 400-foot level of the Victor Con.

Salt Lake County.

Superintendent and Acting Manager A. O. Jacobson of the Columbus Consolidated mine of Alta reports that his company has twenty-two teams hauling ore from the mine to the reduction works.

The Bingham–New Haven aerial tramway is expected to be in operation by October 1. The survey has been completed and Contractor Joseph Dederichs has men framing timbers and excavating for towers. The company has finished a new assay office and equipped it with new apparatus. The water system has been enlarged and gives protection from fire. C. H. Doolittle of Salt Lake City is manager.——The Conger mine, near Bingham, is being opened up by G. G. Hall.

Summit County.

Sinking has been resumed at the Silver King Consolidated mine at Park City. The mine is now equipped to take care of the water, which prevented the work being carried on earlier in the year.

Utah County.

At the Wyoming mine in American Fork canyon fifty men and twenty-five ore teams are being worked by George and F. C. Tyng, the operators.

Wayne County.

A deposit of uranium is reported to have been found 2 miles from Fruita. The deposit is said to lay flat and to be 2 feet in thickness. The ore carries copper and some gold. T. E. Nixon is the owner.

WASHINGTON.

Ferry County.

A. Sharp, mine manager for P. Burns & Co., has taken a bond on the Comstock-Treadwell group, 6 miles north of Orient, from J. F. Mears, J. A. Connolly, H. M. Vantine, Metz, J. H. Clarke and A. Abrahamson, and will start sinking at once.

Pierce County.

It is reported that an arsenic mine, near Elbe, is producing twenty-five tons daily. The plant is said to be the only one in this country where arsenic is taken directly from the ore. It is usually collected from fumes, as in Anaconda and other smelters. The present product is white arsenic.

Snohomish County.

It is reported that the shaft of the Wayside mine on the Stillaquamish, near Granite Falls, is to be unwatered and sunk from the 500-foot to the 1000-foot level. K. A. A. Stahlgren has instructed President Haebecker to resume work.

FOREIGN.

AFRICA.

Transvaal.

The production of gold at the Rand in July is officially announced at 419,505 ounces, the largest on record. The production in June amounted to 412,317 ounces, and the outturn of July last year was 307,840 ounces.

AUSTRALIA.

New South Wales.

The Mining Journal reports that at Barraga the Lloyd Copper Co. have put in a new reverberatory furnace, said to be the largest in the Commonwealth. The State Mines Department has decided that the cost of carriage of trial parcels of ores from the mines to the ore reduction works be guaranteed by the Department, on the explicit understanding that the carriage shall be the first charge upon the proceeds after treatment charges have been met. In the event of the value of the ore being too low to cover the expenses of carriage and treatment, the Department will pay any deficiency out of the prospecting vote. In order that the Department may be assured that assistance to forward any parcel of ore is fully warranted, inquiry will be made into the merits of each application by an inspector of mines, as is

done in respect to ordinary applications for aid from the prospecting vote. The Prospecting Board will have to be satisfied that the ore is worthy of a test, and that reasonable facilities for testing the same do not exist in the district. The board will also determine the quantity which may be forwarded. The Sulphide Corporation, Ltd., Cockle Creek, has agreed to assist the Department by making what concessions are possible in respect of all parcels of ore forwarded with the approval of the Prospecting Board. An important discovery of a silver-lead lode has been made in the Fumberumba district, where a 50-acre lease has been taken up by a Melbourne syndicate. An official report speaks favorably of the find, which is in good auriferous country. The specimens of the ore, with the fluorite forwarded by the Warden, have been assayed by the Department of Mines with the following average results: Gold traces, silver 13 ozs. 15 dwts. 20 grs. per ton; lead 59.3%. Also a very small amount of antimony is present, but no copper. At Cwira creek, 37 miles from Goulburn, a promising copper lode has been discovered, a sample assay giving 50% copper, 12 ozs. silver and 20 dwts. gold. Copper has also been found near Blayney. The proposal of the London syndicate to provide working capital to provide Broken Hill South Blocks with necessary plant, etc., is generally approved, and the work of reconstructing the company, subject to the approval of the shareholders, will be proceeded with. The new company is to consist of 200,000 shares, each £1, fully paid up; 100,000 of these shares to go to shareholders in the present company, and 100,000 shares to go to the syndicate, who, in exchange, are to place £50,000 in cash to the credit of the new concern. Of the 100,000 shares received for the sale it is proposed to give 75,000 to paid-up shareholders of the company. At a recent meeting in Melbourne of the North Broken Hill, an agreement was signed between Rutter Clark, acting on behalf of Messrs. Clark & Robinson of London and the directors of the North Broken Hill Co., by which the directors sold to that firm 10,600 shares for 30s each, cash, and 10,000 shares at the same price, with delivery at or within three months' time. This means that the present company will, if the transaction is ratified by the shareholders, sell its mine and plant to a new company of 140,000 shares of £1 each. Of these shares 10,000 will be held in reserve. Shareholders in the existing company will be allotted share for share, the difference of 20,600 shares going to Messrs. Clark & Robinson at 30s. The capital derived from the sale of the 20,600 shares will be ear-marked for the purpose of sinking a new shaft and developing the mine, and out of the profits in hand, an amount over £12,000, a dividend of 2s per share will go exclusively to the holders of the 109,400 shares in the present company.

CANADA.

BRITISH COLUMBIA.

Boundary District.

The Granby Co. has shut down its smelter at Grand Forks to put in two additional copper furnaces which will be of larger capacity than those at present in use. It will give eight furnaces all told and increase the present capacity of the smelter 50%. The present Dominion C. Co. (the old Montreal & Boston) expects to start a few men at work on the Brooklyn and Stemwinder mines in the Phœnix camp to get the mine in shape for shipping. The new compressor plant and machine drills of the Providence mine have been started.

The Granby Con. Co. has bought the Gold Drop claims in Phœnix camp for $250,000 from the Gold Drop M. Co., of Montreal. The company has purchased from Vaughan & McInnis, prospectors of Phœnix, the No. 13 claim, between the Granby and Gold Drop groups. The diamond drill prospecting by the Granby Co. demonstrated the existence of large ore bodies of similar quality and value to the ore in the Knob Hill and Old Ironsides. The group will be operated in conjunction with the main Granby mines. Specifications are being prepared for the headworks for the new three-compartment shaft to be sunk at the Granby property this fall. The hoist will be electrically driven, and probably of 200 H. P., capable of lifting a five-ton skip from a depth of 1000 feet.

Rossland District

John Harryman of Baltimore, the owner of the O. K. M. Co.'s interest in the O. K. mine, mill and water rights on Sheep creek, near Rossland, contemplates working the base ore in connection with the milling ore. The mine is equipped with a 10-stamp mill and concentration plant.

Superintendent Eugene Choteau is shipping to the Trail smelter from the Cascade Bonanza at Rossland. ——At the White Bear drifting is being done on the 700-foot level to connect with the upraise to the 600-foot level. No shipments will be made from the White Bear until the new 400 H. P. motor is put in.

Slocan District.

It is reported from the Payne mine, near Sandon, that 12-ounce silver ore has been struck in three tunnels. G. F. Ransom is manager.

Vancouver Island.

T. S. Lippy and Grant of Tacoma are to receive a half interest in the June group of the Copper Mountain M. & D. Co., at Quatsino sound, provided that within three years they have completed 1800 feet of underground work, built a railroad and smelter and put in mine equipment.

ENGLAND.

Consul Stephens of Plymouth, England, reports on mining operations in Cornwall and Devon. Last year was not a prosperous one for metalliferous mines in Cornwall and Devon. There was, however, slight increase in the number of persons employed. Cornwall in 1904, with 54 mines at work, employed 3503 persons below ground and 2717 above ground, a total of 6220. Devon, with 24 mines at work, employed 285 persons under ground and 144 above, a total of 429. These figures show an increase of 79 in Cornwall and 60 in Devon. No females are employed in Devonshire mines, but 228 found employment in Cornish mines, all above ground. With regard to the output of minerals, the production in Cornwall last year was: Arsenic, 827 tons; arsenical pyrites, 43; copper ore, 4433; silver ore, 35; tin, dressed, 5986; tin, undressed, 646, and wolfram, 156, making a total of 12,126 tons. Devonshire produced of arsenic, 149 tons; clays, 71,646; copper, 210; manganese, 177; slimes ore, 322; stone, 3187, and tin, dressed, 9; a total of 75,700 tons. Last year Cornwall had 419 quarries at work, employing 5814 persons, and Devon 449 quarries, giving employment to 2299 persons. Of the employes, 4 were females, and these were all employed in Cornwall. Devon during the year produced 921,274 tons of minerals from its quarries, the details being: Chert and flint, 18,504 tons; china clay and china stone, 68,533; potters' clay, 198,897; gravel and sand, 13,755; igneous rock, 87,592; limestone, 471,501; ocher and umber, 600; sandstone, 54,420; slate, 6772, and other minerals, 700. In Cornwall the production was 924,489 tons, comprising: Chert and flint, 3615; china clay and china stone, 582,445; clay, unwrought, 38,616; gravel, 1032; igneous rock, 242,936; limestone, 16,237; sandstone, 11,594; slate, 20,758, and other minerals, 7166.

MEXICO.

Chihuahua.

At the Grenadena mine, near Santa Barbara, the 60-ton concentrating plant will be in operation about September 1. The Grenadena will be mined for zinc principally, as will the San Diego mine near there, belonging to the Torreon smelter people. A concentrating plant, said to be of 200 tons daily capacity, is being put up on this latter property.

Jalisco.

H. M. Sunde is developing the San Jose de las Agujas mine at Navidad. A double-compartment shaft is down 170 feet.——Ore is being shipped from the San Antonio y Anexas silver mines in the Tapalpa district, which were recently purchased by the Chatterton M. Co. from Silviano Camberos of Guadalajara.

Sonora.

(Special Correspondence).—At the Cananea mine the concentrator is being enlarged on each end of the table and vanner room, to double the capacity of the mill, which now treats 1440 tons daily, using eight tons of water to each ton of ore. There is also being built a large steel sampling mill with steel ore bins and belt conveyors, also an immense ore bedding plant of steel, 450x206 feet.

Cananea, Aug. 12.

It is reported that the Babicanora mine, near Baviacora, is again in operation.——Near Huepac, on the Sonora river, Robt. Graham and associates are developing the Anita mine. — The mining camps, El Tiro, La Yaqui and San Francisco de los Llanos, in the Altar district, have been consolidated and named El Tiro. The total population is 1319.——Work of sinking the shaft of the Santo Domingo mine at Aduana is progressing satisfactorily.

NORWAY.

Of iron ore, 39,000 tons was exported from the Fehn mines, near the Nordsjo, where about 230 men were employed during 1904.——At Melo, in Bjarko, in the Tromso district, the presence of iron ore was proved in 1903 by magnetometric tests. In 1904, 4878 tons of iron ore were produced here, containing 57% iron and .02% phosphorus; 2954 tons of this were exported.——Other mines exported smaller quantities, and the total export of iron ore from Norway in 1904 amounted to 45,000 tons, compared with 41,575 tons in 1903.——The briquette works at the port of Guldsmedvik in Moi Ranen have been commenced, and the removal of the surface layer and other preparatory work on the ore fields at Urtvand has been taken in hand, so that 5000 tons per day can be quarried in the summer of 1905. The whole works, which are the finest industrial works in Norway, will be ready by the summer of 1905, and the exportation will then commence; an annual export of 750,000 tons of ore per year is planned for the next few years.

SOUTH AMERICA.

Argentine Republic.

It is reported that a number of companies have been formed in Buenos Ayres to dredge for gold in various rivers in the Argentine Republic and in Bolivia, Brazil and Chile. The mining law of the Argentine Republic does not provide the security of title conferred by the laws and codes of the neighboring countries, especially by Bolivian mining law, but this is largely due to the discretionary powers vested in her administrators. The present Minister of Agriculture, however, has included in his budget for the current financial year a large sum of money, which is destined to effect improvements in the prevailing methods. A large number of dredgers are to be ordered. The severity of the climate will be an obstacle to dredging during the winter months in Tierra del Fuego and Patagonia.

Colombia.

The emerald mines of Muzo are owned by the Government and are among its most valuable assets. Colombia is seeking a loan in foreign markets with which to carry on operations in the mines. Lloyd-Owen was employed by the Government and made a report, from which the following is taken: The Muzo mines are in the State of Boyaca, near Muzo, three days' riding on mule back from Zipaquira, the terminus of the Northern Railway. Under great heat and pressure, due no doubt to further and subsequent volcanic action, these various minerals in the fissures or veins have crystallized in different shapes and forms, according to the various minerals contained in any particular vein or fissure. Under favorable circumstances the most beautiful deep green emeralds have been formed in these small veins, the green color being undoubtedly due to the presence of chrome in sufficient quantity. In other veins the emeralds are found of a light green color, due, no doubt, to the fact that there was not chrome enough present to give the deep green color. In other veins no chrome was present, and as a result the crystals are pure white or colored red or yellow by oxide of iron. Many of the crystals are pure silica and others have various minerals combined with the silica. The general tendency in these emerald-bearing rocks is to form crystals of emerald of green color, and the quality of the emerald, if it is clear and free from flaws, depends upon its size and color, the darker green being the most valuable. The thickness of the emerald-bearing strata at the present workings of the Muzo mines varies from 100 to 200 feet. Although some emeralds are found in the upper strata, the amount is inconsiderable and practically all the emeralds are found in the lower strata. Large quantities of barren rock and strata have to be removed in order to get at emerald-bearing ground by open workings, and as it would not pay to remove this overburden by hand labor water is employed. A small stream coming down the mountain side above the workings is intercepted and caught in a tank. When this tank is full the water is released, and, rushing down and through a long, winding ditch, finally comes to some of the debris and washes it down the valley, where it accumulates until washed away by the stream from the cross hills. It is necessary that after the present accumulation of debris has been removed work should at once be commenced to remove the overburden from the next portion of emerald-bearing ground proposed to be worked, and this should be pushed on as fast as possible during the wet season, when water is available. There should never be less than twelve months' work of emerald-bearing strata exposed and clear of debris. It is stated that the production of the mines for the period included between May 1, 1904, and January 31, 1905, was as follows, stated in carats: First-class emeralds, 262,548; second-class, 467,690; third-class, 22,700; fourth-class, 16,000. These figures give a total of 768,938 carats sent to Bogota in the period named.

Peru.

A. W. McCune, in an interview at Salt Lake City, Utah, said that the Cerro de Pasco mines, 210 miles from the city of Lima, are being connected to the coal mines, 17 miles distant, where the Cerro de Pasco Co. will have its coke ovens. The copper smelter will go into commission about Nov. 1. The plant was originally designed to handle 1000 tons of ore per day, and equipment has been provided accordingly. To begin with, only the first unit of 500 tons will go into commission, but the capacity will be gradually brought up to the maximum. The labor question in South American countries is not a serious one, and Mr. McCune finds that the natives give very good satisfaction after a little training.

Commercial Paragraphs.

THE Hercules Gas Engine Works, 215 Bay street, San Francisco, Cal., were totally destroyed by fire on the 13th inst.; loss $100,000, insurance $25,000. The works will be immediately rebuilt.

H. P. GILLETTE AND G. H. GIBSON have formed a partnership as "advertising engineers," under the name of the Geo. H. Gibson Co., with offices in the Park Row Bldg., New York City.

THE Compressed Air Machinery Co. of San Francisco, Cal., has recently shipped four of the Word Bros. improved drill makers and sharpeners to the Oliver Iron M. Co. of Duluth, Minn., making a total of seven machines placed with this company.

THE Wellman-Seaver-Morgan Co., Cleveland, Ohio, have established a branch office at No. 216 Dooly Block, Salt Lake City, Utah. H. V. Croll, M. E., has been appointed manager thereof, and inquiries addressed to the Salt Lake City office will have his personal attention.

THE S. H. Supply Co., Denver, Colo., report the following recent shipments of machinery: Two No. 1 Wild mills, suitable for mule-back transportation to Mexico; No. 3 Wild mill to California; fifty-ton cyanide plant complete with No. 2 Wild mill to New Mexico; complete fifty-ton concentrating plant with No. 2 Wild mill to Arizona; 75 H. P. Lidgerwood double-drum hoist to Mexico.

THE Colorado Iron Works Co., manufacturers of ore milling and smelting equipments, state that their New York sales agency, formerly in charge of the Traylor Engineering Works Co., 114 Liberty St., New York City, has been discontinued, and for the present the company is not represented there, all inquiries, requests for specifications, estimates, etc., being handled direct from the main office at Denver, Colo., until further notice.

THE Pelton Water Wheel Co. report orders from the Homestake M. Co., Lead, South Dakota, for one 800 H. P. Pelton water wheel unit direct connected to an electric generator; the Nevada Power M. & M. Co. for an additional Pelton wheel, 3000 H. P. maximum capacity, direct connected to an electric generator and operating under a head of 990 feet. This company is installing two Pelton wheels for direct connection to 750 K. W. generators and proposes to transmit power to Tonopah and Goldfield, Nev. Through Mitsui & Co., San Francisco, was placed an order for 500 H. P. wheel for use in electric light station in Japan.

Trade Treatises.

A neatly illustrated booklet from the Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York City, describes the construction and operation of the "Radialax" coal cutter.

A finely executed folder from the De La Vergne Machine Co., Foot of East 138th St., New York City, N. Y., exemplifies the construction of the Koerting gas engines, suction and pressure producers.

The Powell "White Star" valve is described in detail with sectional illustrations in a little book issued by the Wm. Powell Co., 2525-2531 Spring Grove avenue, Cincinnati, Ohio, showing the value and economy of their use.

Personal.

J. H. CURLE has returned to London, Eng., from South America.

H. K. WHEELER has returned to Los Angeles from San Francisco, Cal.

CHARLES A. MOLSON of Salt Lake City, Utah, is on a visit to New York.

W. A. FARISH is examining mines in the Clifton-Morenci district of Arizona.

RICHARD A. PARKER of Denver, Colo., has returned from Salt Lake City, Utah.

JOHN C. DALY of Salt Lake City, Utah, has been visiting in San Francisco, Cal.

J. C. GOODWIN of Tempe, Ariz., is visiting the Lewis & Clark Exposition, Portland, Or.

F. R. FIELDING, who has been dangerously ill in San Francisco, Cal., is reported convalescent.

J. PARK CHANNING of New York City is in Salt Lake City, Utah, after visiting San Francisco, Cal.

T. R. HENAHAN, manager Silverton M. Co., Silverton, Colo., has returned there from Chicago, Ill.

GEORGE E. WEBBER, manager Rand Mines, Ltd., is on a visit to California from Johannesburg, S. A.

ERNEST GAYFORD'S temporary address is "The Southern Manufacturers' Club, Charlotte, N. C."

W. L. HONNOLD is taking a holiday in Wisconsin. He will return to Johannesburg, S. A., in October.

C. GARDNER has been appointed manager Garden Wall M. Co., working lead mines near Wiota, Wis.

T. J. LUDLOW of Berkeley, Cal., has taken a position with the Alaska Central Railway, at Seward, Alaska.

J. W. CONNER, manager Veta Colorado M. & S. Co. of Parral, Chihuahua, Mexico, has been in New York City.

T. A. RICKARD is in Nova Scotia, as advisor to the Provincial Government in its effort to stimulate gold mining.

JOHN ROSS JR. has returned to the Wildman mine, at Sutter Creek, Cal., from professional business in Nova Scotia.

G. G. VIVIAN, manager Hidalgo mines and smelter at Sultepec, State of Mexico, Mexico, has been at Georgetown, Colo.

H. E. WILSON, manager Eureka Nest Egg and Erie mines, White Pine, Colorado, has returned there from St. Louis, Mo.

CHAS. M. GUNN, general manager Columbia Engineering Works, Portland, Or., has returned from a brief California visit.

C. T. DURELL, manager Gold Reef mine, Gilt Edge, Mont., has resigned to become manager Spotted Horse mine, Maiden, Mont.

EDWARD HOOPER will leave London, England, in September to examine the Great Boulder Perseverance mine in Western Australia.

N. W. HAIRE of Ironwood, Mich., succeeds W. E. Parnall as manager of the Bigelow Syndicate's interests in the Lake Superior country.

R. GILMAN BROWN of San Francisco, Cal., is supervising experiments with the Moore process at the mill of the Standard Con. Co., at Bodie, Cal.

A. F. ROGERS of Columbia University has been made assistant professor in the department of geology and mining at Stanford University, Cal.

NORRIS ENGLISH, superintendent Darien G. M. Co., at Cana, Panama, has returned to San Francisco, Cal., and will probably remain until spring.

W. GILLETTE SCOTT, general manager and superintendent of mines for the Great Western Gold Co. at Ingot, Shasta county, Cal., has resigned.

F. MORGUES, general superintendent Quintera M. Co., at Alamos, Sonora, Mexico, has resigned and will leave for Paris. George La Brun is his successor.

CHARLES M. BECKER, manager Stratton's Independence, Cripple Creek, Colo., has gone to New York to meet F. W. Baker of the Venture Corporation.

W. F. COCHRANE has been chosen president and manager Great Northern Mines Co., operating in Trout Lake division, N. W. Kootenay district, B. C.

S. B. CHRISTY, professor of mining at the University of California at Berkeley, Cal., has returned from a visit to the mining camps of Colorado and Nevada.

E. H. WEBSTER, formerly superintendent Grand Central mine, at La Colorada, Sonora, Mexico, is assistant manager Dolores mine, Minaca, Chihuahua, Mexico.

Books Received.

Each trade and profession has a language of its own, and the expression and interpretation thereof is often puzzling to the uninitiated. The vocabulary of the machinist is admirably presented in "Machine Shop Tools and Methods" by W. S. Leonard. This has been written for the instruction of students in the machine shop, and is particularly useful in that it not only defines the tools, but tells how they should be used to get certain results. The book is written so as to be easily understood by students who know very little of practical machine shop work, and is consequently exhaustive in its description of even the commonest machine tools. The book tells the why and wherefore of many methods of doing certain work that machinists may have been doing for years, but, having been taught how to do it when apprentices, they have not learned the reason for so doing. It will prove valuable for every student in an engineering college, and a fine reference book for anybody interested in machine shop tools, as it treats of the most modern machines. For reference in a commercial machine shop the description of the construction and use of portable pneumatic tools would be much appreciated, because these tools are constantly used in large shops, but their construction and inner workings are only understood by the tool keeper and his assistants. The treatment is logical and comprehensive, yet eminently practical. It is published by John Wiley & Sons of New York City and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $4.

Folio 124, "The Mount Mitchel Quadrangle," of the U. S. Geological Survey, describes the geography and geology of a part of North Carolina and Tennessee. Soapstone, talc, mica, precious gems, corundum, marble, serpentine, building stone, graphite, magnetite, brown hematite, chromite, lime and brick clay are the economic minerals.

"New or Imperfectly Known Rodents and Ungulates from the John Day Series," by W. J. Sinclair, a bulletin of the Department of Geology at the University of California, Berkeley; price, 25 cents.

Latest Market Reports.

SAN FRANCISCO, August 18, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27⅜d (standard ounce, 925 fine); New York, bar silver, 60½c, refined (1000 fine); San Francisco, 60½c; Mexican dollars, 46c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, $15.62½; Lake, 1 to 3 casks, $15.62½@15.77½; Electrolytic, 1 to 3 casks, $16.00; Casting, 1 to 3 casks, $15.25 @ 15.50. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £69 5s spot per ton.

LEAD.—New York, $4.70; Salt Lake City, $3.50; St. Louis, $4.52½; San Francisco, $3.70, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £13 18s 9d ℔ long ton.

SPELTER.—New York, $5.80; St. Louis, $5.18; London, £24 12s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $32.55@32.85; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 35½c; less, 35½c; bar tin, ℔ lb., 35@37½c. London, £149 15s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.00c; San Francisco, Plumbers', 100-lb. lots, 19.00c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.85; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$21.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 12½c; Hallett's, 13c; San Francisco, 1000-lb. lots, 11c; 300@500-lbc. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12½c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10½c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

OILS.—Linseed, boiled, bbl., 64c; cs., 69c; raw, bbl., 62c; cs., 67c; Lucol oil, boiled, bbl., 56c; cs., 61c; raw-bbl., 54c; cs., 59c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

DETORSION TIMBER SQUARE.—No. 796,645. Aug. 8, 1905. James Herche, San Francisco, Cal. The object of this invention is to provide for such corrections in the timber as will enable the operator to correctly effect the desired results. The device comprises a rectangular block with intersecting guides parallel with its sides, blades and means for adjustably holding them in said guides, a level fixed parallel with two of the sides of the block, and standards adjustable upon the horizontal blade. There are other details of construction adapted to bring about the desired result.

PROTECTIVE CAPS FOR TUNING PINS.—No. 796,677. Aug. 8, 1905. Isidor B. Rosencrantz, Alameda, Cal. This invention relates to a removable covering for the tuning pins of pianos. It is well known that the strings of pianos and other instruments are more liable to get out of tune where they and their tuning pins are subjected to any considerable or sudden changes in temperature. This is due particularly to the tendency of the pins to expand or contract, and so put the strings out of tune. The object of this invention is to provide a simple, inexpensive, practical, protective cap or covering for the tuning pins which may be quickly and easily applied to the pins of any piano, and which will grip all the pins alike to hold it in place, and at the same time will allow of the proper circulation of air about all the pins and not allow one pin to be affected by temperature more or less than any other pin. It consists of a protective cap for piano tuning pins, composed of flexible material and of greater length than width, and having interior longitudinal integral portions to engage the opposite sides of all the pins alike and to retain the cap in place, at the same time permitting the free circulation of the air between the several pins.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR WEEK ENDING AUGUST 1, 1905.

796,172.—ORE DRESSER—Anderson & Bennie, Clifton, Ariz.
796,390.—ORE DRESSER—Anderson & Bennie, Clifton, Ariz.
796,285.—BOTTLE—S. E. Bell, Represa, Cal.
796,186.—ROAD ROLLER—A. E. Burns, Los Angeles, Cal.
796,114.—THERAPEUTIC APPARATUS—H. E. Currey, Baker City, Or.
796,197.—UNDERREAMER—E. Double, Los Angeles, Cal.
796,118.—FISH TANK—J. B. Duryea, Tacoma, Wash.
796,305.—HOSE COUPLING—L. W. Epley, Colville, Wash.
796,204.—LIFTING JACK—E. H. Goodwin, Olympia, Wash.
795,972.—CURTAIN POLE—M. M. Harding, Monrovia, Cal.
795,837.—FLOWER STAND—Hyde & Buchanan, Wadsworth, Nev.
796,125.—LUBRICATOR—H. P. Josewski, S. F.
796,228.—ROCK DRILL—E. R. Langford, Los Angeles, Cal.
796,232.—ANIMAL DIPPING MACHINE—J. Manifold, Willows, Cal.
795,997.—SURFACE DRESSING MACHINE—D. Mathews, Los Angeles, Cal.
796,001.—PLANE—J. H. McGhan, Baker City, Or.
796,143.—LINE GRIP HOLDER—A. Nord, S. F.
796,253.—TREATING STONE—H. Ryan, Seattle, Wash.
796,150.—FRUIT SHEARS—T. A. Ryles, Pomona, Cal
796,156.—FRUIT PACKING MACHINE—S. H. Shelley, San Jose, Cal.
795,866.—INHALER—J. R. Spanogle, Athena, Or.
796,265.—STEAM BOILER—C. A. Sturm, Castlerock, Wash.
796,164.—DRILL HOLE ENLARGER—T. M. Topp, Raymond, Cal.
796,377.—PIPE FITTING—F. Walker, Los Angeles, Cal.
796,028.—HAME FASTENER—W. G. Youngs, Montesano, Wash.

MINING AND SCIENTIFIC PRESS.

Whole No. 2351.—VOLUME XCI. Number 9. SAN FRANCISCO, CAL., SATURDAY, AUGUST 26, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Situation a Factor in Mining.

In the development of a new mine or a new mining district the situation is often one of great importance in securing the necessary capital for development and equipment. Naturally it would seem that the situation might, to a great extent, dominate all other considerations; but such is not always the case, though often there is less difficulty in securing the needed capital for opening and equipping a new mine in a situation where the conditions are favorable than where they are difficult. There are, however, a sufficient number of exceptions to be interesting. In Colorado no situation seems impossible to the miner and capitalist. If the vein only shows up sufficient value to make it attractive, the necessary money is usually promptly forthcoming. No altitude seems too great. No difficulties of transportation, apparently, are insurmountable. If railway facilities are wanting, railroads are built. If expenses can be reduced by concentration, concentrating mills are hauled into the most rugged and highest mountain basins adjacent to the mines, and an aerial tramway forms the connecting link. Nature obtrudes many obstacles to success, but the ingenuity and enterprise of the miners surmount these as fast as they present themselves. Idaho has offered many difficult situations to the progress of mining enterprise, but where the mines justified it, as in Colorado and Idaho, these difficulties have been overcome. In earlier days in California—thirty years or more ago—there were numerous companies operating mines in the Sierra Nevada. A large amount of gold and silver was taken out, but at great cost. Hundreds of thousands of dollars were expended in the construction of roads alone. Mining and milling machinery were hauled in and an active campaign was carried on. These enterprises, for most part, are now idle and abandoned. The mechanical difficulties were overcome, but there were other troubles as great or greater. The ores were, for the most part, base, and the extraction was both low and expensive. Supplies and wages were higher than now, and results were not always satisfactory. Now things are different. Most of the ores can be reduced successfully, supplies and wages are lower than at that time, and the mechanical appliances and methods are both superior to those in use in the former years. Notwithstanding these facts the mines of the high Sierra are mostly idle. The California miner, as a class, has found mining in the foothill region, surrounded by gardens and orchards, with the railway station within easy reach, far more to his liking than a life among the towering, snow-clad peaks of the Sierra. He loves to look upon them from a distance, and in the sweltering heat of a midsummer day wishes himself somewhere amid the snow fields, on a pleasure trip, but he seldom thinks of the mining possibilities awaiting a more energetic fellow.

The accompanying illustrations, and those on page 137, are of the equipment of the Nickel Plate mine, near Hedley, B. C. Here is an instance where difficulties of situation did not count for much. When this property first came to the attention of the manager, it was many miles off the main lines of travel surrounded by high and snow-capped mountains. There was little inducement to even visit such a desolate wilderness, other than the story of a good-sized vein of rich gold rock. This sort of thing tempts many engineers to make what proves to be "wild-goose chases," but in this instance, the "story" seemed well founded. Development was commenced in midwinter and continued uninterruptedly. Gradually the property was equipped, and is now going steadily, increasing in magnitude of operations, equipment and value. The difficulties of situation have largely been overcome. Propositions of this character demand something more than money. They require that the engineer understand his business and that he be able to judge fully andwith an approximation to exactness what is required, what will it cost, and what the probable result will be. If these problems can be satisfactorily solved then the investment may be safely made, or the project dismissed as too hazardous, or of no value at all.

Mill of the Nickel Plate Mine, Hedley, B. C. (See Page 137.)

THERE is a saying among geologists, especially those who devote their attention more particularly to the economic features, "Once mineral, always mineral." This refers to the probabilities of minerals of economic importance occurring through a succession of geological formations. Thus, in the Black Hills of South Dakota it is positively known that the Algonkian schists were gold-bearing in pre-Cambrian times. The overlying Cambrian, Silurian and Cretaceous rocks are also mineral-bearing. Whether still later rocks—the Cretaceous and Tertiary, which no doubt also at one time occurred there, but which have since been removed by erosion—were also mineral-bearing, it is impossible to say. In this Dakota instance, at least, the saying seems well founded.

IN view of the rate at which gold is being absorbed in dentistry at the present day, the "prehistoric burying ground" of the distant future is likely to prove a rather profitable gold mine.

MINING AND SCIENTIFIC PRESS.

ESTABLISHED 1860.

Published Every Saturday at 330 Market Street, San Francisco, Cal.
Telephone, Davis 771.

ANNUAL SUBSCRIPTION.

United States, Mexico and Canada.....$3 00

IT is said that D. G. Delprat, manager of the Broken Hill Proprietary mines, at Broken Hill, N. S. W., has conspicuously posted in the company's works a sign bearing in effect the following legend: "Look around and see where money can be saved. Any suggestions in this direction, together with the name of the writer, if placed in the box beneath, will receive the prompt attention of the manager." Mr. Delprat is a well-known and successful mine manager, and the above appears to indicate why he is successful. He evidently endeavors to surround himself with men who use their brains as well as their hands. Without doubt, the workman who makes a valuable suggestion receives substantial reward for his earnestness in behalf of his employer. The experienced manager may sometimes learn valuable lessons from the most humble man on the payroll. There are those whose success has carried them so far that they feel no longer the need of advice or suggestion from their peers, to say nothing of those in their ranks, but the wise manager never rises to this dangerous height. The ideas of the men who daily come in contact with the details and the drudgery are often well worthy of consideration.

A MINE bookkeeping system may be made more or less elaborate according to the needs of the business or the wishes of the manager. If itemized costs be desired, it is impossible to obtain them without a careful and complete segregation of accounts. Every department concerning which detailed information is wanted must of necessity have its separate account. The various charges should be made on exact information, and not by guess, or by an apportionment among several departments, as, for instance, the amount of powder used on each of the several levels of a mine. An accurate record must be kept of the powder going to each level, and if any be taken from that level to another place, the level from which it was taken should be credited on the books with it, and the amount charged against the place where it is actually used. A bookkeeper who was more noted for his love of leisure than for the energies devoted to his business undertook to apportion the powder used among the several levels and working places, gaging the several amounts by the number of men employed in each level. Against one level several hundred pounds of powder were charged, when during that particular month only retimbering and repairs had been going on, a knowledge of which fact by the manager at once exposed the fallacy of a scheme so foolishly devised and applied.

"Tricks of the Trade."

That there are "tricks in all trades," has come to be accepted as an axiom. There are probably more "tricks" in cyaniding than in any other branch of metallurgy. By "tricks" in this instance are not meant deceptive or crafty performances, but a certain adroitness in manipulation, or a keen understanding of the requirements in perplexing situations. The field of experimentation in cyaniding is broad, and if followed intelligently and faithfully, it will bring out the latent powers of the operator in a manner that few other callings can equal. In cyaniding, "rule of thumb" and precedent must be abolished if the highest success is sought. Because a successful operator has accomplished what was acknowledged to be a difficult task at one place, is not proof positive that he can do the same thing elsewhere in exactly the same manner. He may have to modify his treatment or method considerably. He must be flexible. The only way in which he can afford to be stubborn is to persistently refuse to accept defeat, but if failure is succeeded by failure, try again along somewhat different lines, but always be rational.

A difficult ore problem presented itself to several cyanide operators. Filter-pressing was found out of the question. The slimes flowed like water through every grade of filter cloth. When the fabric was fine enough to act as a filter the meshes clogged with the slime and soon filtration either ceased altogether or the slimes were forced through with the solution. Another operator tried to treat this same material by agitation and flocculation with lime. The pulp would not flocculate. More lime was tried, but without success. Another operator, more willing to try extremes in an emergency, undertook the same plan, starting with very little lime. It did not do as well as was required, but was an improvement. The caustic lime was then pulverized, screened and scattered over the tank with a shovel—an ordinary 2½-gallon bucket of lime to a 30-foot tank of slimes, so fine that a high power microscope was required to see the individual particles in the sludge when spread on a slip of glass. In an hour the pulp was clear. The usual filter bottom with canvas was used and filtration was discouragingly slow, particularly the last 18 inches of sludge. An experiment was tried. Cocoanut matting overlaid by jute bagging was tried, and the filtration after decantation was rapid and complete.

These instances merely illustrate the need of adaptation of the methods to conditions. The latter usually cannot be materially changed, the methods can be, and it is up to the cyanide operator to be fully acquainted with all the "tricks of his trade," and to practice them whenever it is required of him to devise a new method or to improve an old one.

Equity in Mine Taxation.

Several of the mining States of the West are struggling with the problem of mine taxation. All who have ever had experience with this aggravating proposition know that it is a matter not easily dealt with to the satisfaction of all concerned. The owner of the operating, paying mine thinks himself entitled to favorable consideration, for upon the industry under his direction depends, to a proportional extent, the prosperity of the town, district or county in which he operates. If he and the other mine operators of the county were to close down their mines, all other industries in the district would probably cease to exist with them, for all are built up by and depend directly upon the mining industry. Let the mines shut down and deserted villages would quickly result. The district would soon be depopulated and the region revert to a wilderness. The owner of the unprofitable mine declares he is already placed at a great disadvantage and an exception should be made in his favor, as he is spending money in an effort to develop a mine which some day may become profitable, and he will then be able to contribute to the support of the county and State Government. The owner of the idle mine says he cannot afford to pay taxes on a property which brings him in nothing, and protests vigorously against taxation. In Arizona there is serious talk at the Territorial capital of raising the assessment of all mining property in the Territory—each county to have its assessment raised from 100% to 15,000%, according to the existing assessment and conditions in the respective counties. That this proposition is meeting with vigorous resistance, it is needless to say. In South Dakota the Mining Men's Association, which is the representative body in that section, is earnestly protesting against a threatened increase in assessment. The proposition is by no means a new one, and many schemes have been tried by means of which to raise the money necessary to meet the expenses of county and State Government. Direct taxation on valuation of the mines, taxation of improvements, bullion, or output tax—each of these and others have been tried, but from the miner's standpoint none of them are popular.

The Cheapest Mining.

South Dakota still continues to attract attention, as one of the regions of cheap mining in the West. The Black Hills is a section of the mining country favored above some others in many ways—there usually being abundance of timber and water—but, on the other hand, it labors under some disadvantages. The extremes of temperature are its greatest drawback, but, notwithstanding the fact that the thermometer ranges from 110° in midsummer to 40° or more below zero in midwinter, little time is lost in mining operations due to the weather. The Wasp No. 2 mine, situated in the Black Hills, on Yellow creek, about 2 miles south of Lead, and which has become somewhat noted for the heavy blasting operations carried on there, has recently fired another "big shot," in which it is said 7000 tons of ore was broken down in the open cut. The ore shoot lies flat, and affords excellent opportunity for such feats in mining. Unfortunately, the cost of mining and milling at the Wasp is not available, but it is known that by cyaniding a profit is made on ore assaying under $5 a ton.

Elsewhere herein is the description of mining practiced at the Benedict mine, in Pennington county, in the southern Black Hills, where gold ore is being mined and milled at present for about 35 cents per ton, which is about as cheap as the cost of mining and milling is done any place. At one time, about 1890, mining and milling were accomplished for (it was stated at the time) less than 50 cents per ton, at the Dalmatia mine, in El Dorado county, Cal., but as soon as the open cut method was no longer available costs went up, as the workings went deeper.

Two miners picked down and sent to mill 115 tons of ore daily, or at the rate of 7½ cents per ton. The mill equipment consisted of three Huntington mills and ten stamps. The ore contained $2 per ton. It seems likely that if the cost of power on capital account be added to the Golden West statement it would bring the expense to about 40 cents per ton, which is still less by about 10 cents per ton than the cost at the Dalmatia.

At the Big Indian mine, near Helena, Mont., mining and milling were being done in the summer of 1903 for $46\frac{7}{10}$ cents per ton. This mine was worked by the open cut and mill hole method, 310 tons of rock going to the 60-stamp mill daily. In this instance two expert miners did all the drilling. Besides these there were employed the foreman, a carman, blacksmith and twelve laborers. Miners received $3.50 per day and laborers $3. The mill capacity was high—over five tons per stamp. In these charges were included power, insurance and general expenses.

It does not appear that the managers of any of the above mentioned properties have any cause to blush for their record as expert and careful miners. This sort of work cannot fail to stimulate others to emulate the very good example these several performances afford.

CONCENTRATES.

THE mineral lands on the Uintah, Utah, reservation will not be open for entry till October 27, 1905.

NEARLY 50% of the zinc product of the United States is absorbed in making galvanized iron and large amounts are used in the manufacture of brass.

WOLFRAMITE AND SCHEELITE may occur associated in the same vein or deposit—one being tungstate of iron and manganese and the other tungstate of calcium.

SOME mill men consider graphite an excellent lubricant for cams in stamp mills; others prefer the old-fashioned "dope." The graphite eliminates the danger of grease.

DURING the fiscal year ending June 30, 1905, the British Columbian Government bounty of 50 cents per 100 pounds, in lead produced therein, aggregated $332,418, which includes the bounty paid on exported lead.

PENSTOCKS, sluices, mill races and other places where ice forms may be quickly cleared of the obstruction by the use of water under pressure, as in hydraulicking. The ice melts or breaks up under the continued force of the stream.

A ROUGH pine board, placed below the lip of the mortar and at the head of the apron plates of a stamp mill, affords an excellent indication of the condition of amalgam within the battery, and is a guide to the feed of quicksilver.

THE element columbium (Cb) is the same as niobium. It is a metal of steel gray color, having a brilliant luster, and has an atomic weight, as referred to oxygen, of 94. Niobium is the name more commonly used in the United States, though in England it is still often called columbium.

UP to the present time all efforts to reduce cinnabar by wet processes have proved commercially unsuccessful. The distillation of the mercury by fire applied directly to the ore, or to the concentrated ore in retorts, has thus far been the only successful method of treatment.

MARBLE is usually intended to include those rocks composed of carbonate of lime or of lime and magnesia—limestones and dolomites—but the term has been extended to embrace some other varieties of stone, such as some altered varieties of serpentine, and called verde antique marble.

BITTERN is the liquid remaining after sodium chloride and some other salts have been crystallized from sea water by evaporation. Bittern contains bromine in the form of bromide of magnesium and bromide of sodium. Bromine also exists in certain mineral springs. Bromine is the only element beside mercury which is liquid at ordinary temperatures.

THE true onyx is silica and occurs in nodular masses having various colored bands—black and white or shades of red and white, yellowish red, brown and white, etc. In recent years some banded aragonites (calcium carbonate) deposited by calcareous springs have also been called onyx. The Mexican onyx and that from Big Bug, Yavapai county, Arizona, is of this kind.

SO FAR as known to "Concentrates," the largest mass of native copper ever found was taken from the Phœnix mine, in Keweenaw county, Mich., and weighed 500 tons. Its extraction is said to have necessitated the calling of a $20,000 assessment. This large mass was cut in place with long-handled chisels, to sizes that could be hoisted, by men who make a specialty of that work.

AIR COMPRESSORS may be fitted with automatic devices which regulate the pressure within fixed limits, as, for instance, 90 to 100 pounds. When the pressure falls to 90 pounds the machine starts up automatically. When the pressure has been raised to 100 pounds the machine automatically cuts off and the compressor stops, only to start up again when the pressure is down to 90 pounds.

MICA SCHIST, hornblende schist and some other metamorphic rocks are often found mineralized, more or less silicified, and gold-bearing along a certain strike, with rather indefinite walls, sometimes none at all, the commercial result being the only definite limitation when working the deposit. Although such deposits cannot be defined as veins, this need not render them less valuable, as many such deposits have been worked with good profit.

IN some instances concentration can be accomplished by rather coarse work, resulting in large capacity per crushing unit. A well-appointed modern mill, with hydraulic classifiers, etc., would do much closer work, but where the product is low grade the less scientific method produces the best economic results. Where the concentrate is high grade the proposition assumes a different phase and close sizing, and classifying before concentration are justifiable.

POWER has been successfully and economically transmitted by wire rope for considerable distances—upward of a mile—the rope running on idlers attached to low towers. This line was employed in running a pump to supply a quartz mill with water, the power being transmitted by the mill engine. In another instance power was transmitted from a mill run by water power half a mile up hill to a hoist. This also was run by wire rope and proved satisfactory and economical.

THE quantity of water discharged through the nozzle of pipe under known head may be approximately determined as follows: Extract the square root of the head in feet and multiply this by 8.03. The product will equal the spouting velocity in feet per second. Multiply the area of the nozzle at the mouth by this velocity and the result equals the cubic feet of water discharged per second. Thus a 6-inch pipe under a 400-foot head will discharge $\sqrt{400} = 20 \times 8.03 = 160.6 \times 28.27 = 4523.8$ cubic feet per second.

THERE should be no difficulty in concentrating scheelite from its matrix. Quartz, feldspar and the other ordinary rock-forming minerals have a specific gravity of about 2.6, that of scheelite being 5.9 to 6.1, or more than twice as heavy as minerals of the gangue. Pyrite, which usually concentrates readily, has a gravity of 4.9 to 5, being considerably below that of the tungsten ores. If the proper machinery is used in crushing and concentrating, the scheelite should give no trouble whatever. Tungsten ores are successfully concentrated in Boulder county, Colo., and elsewhere.

THE single-phase commutator-type alternating current hoisting motor is essentially a series wound motor and may be controlled by any method which changes the impressed voltage. With alternating current there are several ways of doing this, but the simplest method is by means of a rheostat such as is used in controlling direct current series motors. Recently automatic hoist controllers have been placed on the market which produce an even and proper acceleration without regard to personal characteristics of the operator and without danger to the motor or operating mechanism.

A GRAVITY TRAM is better suited to a fairly uniform gradient than an aerial wire tram, where the distance between terminals is not too great; but where there are many inequalities of surface, such as intervening canyons and gulches, ridges, etc., the aerial tram is far superior, both in first cost and in operating expense. The gravity tram is not well adapted to numerous and decided changes of grade. The latter can usually be satisfactorily constructed with three rails, with a turnout at the center. The curve at either end of the turnout must not be sharp, or cars may frequently be derailed.

IT is estimated that for good ventilation in mines at least 100 cubic feet of fresh air should be supplied for each man employed underground. Some mines have ventilating plants which actually supply this amount, but the system of air distribution is so poorly arranged that in some places the fresh air is in excess of requirements, while in others it is deficient. It is evident that a single machine drill exhausting 180 cubic feet of air per minute when in actual operation supplies no more air to two men working there than they actually need, and that it falls below the theoretical requirement.

DAMPERS in ventilating pipes in mines, employed to deflect air currents, should be made of heavy plate, similar to that used in turn sheets, for the heavy Russia iron usually used will not stand the shock incident to blasting, but double up around the damper rod. The pipes must also be made of material heavy enough to resist collapse, due to the momentary semi-vacuum produced within the pipe by the explosion. Where it is necessary to carry the pipe close to the blasting face, it is well to either use old pipes or three or four lengths of extra heavy pipe to withstand the damage of flying rocks.

USUALLY the effect of explosions is most noticeable where there has been the most resistance. The explosive force exerted on the air is not noticeable, but the effect on the ground or on rock where powder has exploded is clearly evident. This has led many to think that the explosive force of powder is downward only. If a stick of powder be placed in a horizontal crevice in the rock, or in a hole drilled horizontally into rock, and the burden given it not too great, the overlying portion of the rock will be shattered and blown off. If the explosive force were downward only, the overlying rock would not be materially affected.

FEW of the surface equipments in the Missouri-Arkansas zinc-lead field are extensive or expensive for the reason that the individual ore shoots or deposits are comparatively small though numerous. This condition renders a surface plant of only transitory value, and it has usually soon outlived its usefulness, and may be transferred to a new place. For this reason head frames are made of light timber—2x6 and 2x8 pine, and the hoisting engines are mostly small, not being required generally to hoist from a greater depth than 200 feet. It is generally cheaper to sink a new shaft than to continue to tram ore 700 to 1000 feet underground only a few feet below the surface.

THE first hydraulic mining of which there is an authentic record was at Yankee Jims, a placer camp in Placer county, Cal., about 3 miles west of Forest Hill. A ditch was dug along the hillside and from this a flume was built outward toward a small ravine, where the mine had been opened. This flume was carried out until it had reached a point 40 feet above the ground. Here the water poured into a barrel, to the bottom of which was attached a hose or pipe of rawhide. The nozzle was a tin pipe about 4 feet long and shaped like an ordinary horn, having an opening 1 inch in diameter at the end. With this small and simple apparatus E. E. Mattison, the inventor, soon proved the superiority of his device over shoveling, and the idea was at once adopted and quickly improved and enlarged upon.

BLASTS have been successfully discharged by means of the electric spark for many years. The spark is generated in a device made for the purpose, the spark being created by friction. If all the holes loaded and primed are connected to the electric wires, all of the holes are discharged simultaneously, which frequently results in greater or less damage to timbers. If it is the intention to shoot the entire round at once by means of the electric spark, the holes should be given a lighter load than where they are fired miscellaneously or after a prearranged succession, by cutting the several fuses of different lengths. Efforts have been made to produce a fuse which would make it possible to fire holes previously loaded and connected up at one time, so that they might be discharged in series, but this attempt has as yet only met with partial success.

A BUCKET from a vertical shaft may be easily dumped by means of what is known as a "trip rope." This rope is secured at some point above the shaft, usually 12 to 15 feet, and at a place which will cause the bucket to dump at the desired spot, either in front of or behind the shaft, into a bin or car, or on the ground, as desired. The rope is provided with a hook, which is caught by the bucket tender into the ring beneath the bucket. When the engineer slacks the hoisting rope the bucket is drawn either backward or forward by the trip rope, and at the same time inverted and the contents fall wherever desired. At some shafts two ropes are used, one in front of the shaft, the other behind it. By this means ore is dumped at one place and waste at another. Where the trip rope is used the shaft should be provided with doors, which may be closed before the bucket is dumped. This gives greater security to the men below, and without such precaution the use of the trip rope is extremely dangerous.

IT is dangerous to store large quantities of high explosives in the mine, as frequent disaster from the practice shows. A magazine built of stone is considered by many the best place in which to keep dynamite and other high explosives. Others think light frame structures covered by corrugated iron better than heavy stone magazines, as in the event of an explosion, there is less flying debris to increase the danger. Still others believe the underground magazine better than either of the former. Without doubt a more even temperature can be had in an underground magazine, and such a storage place is superior to all others if it be dry, but this fact does not warrant the placing of powder in mine workings that are in use or which are connected with the main exits, and in a situation between these and the working faces. If there are abandoned workings in the mine, at some point distant from the main tunnels or shafts, and in a place where no great damage would result to the permanent improvements, nor to the workmen employed should an explosion occur, in such old workings a good storage place for powder may be found. Not more than a day's supply should be kept at the loading bench on any level, in the mine, and the caps should be kept in a separate place.

WHERE gold ores contain copper it is often difficult to secure satisfactory results by the cyanide process. Metallic copper is slightly soluble in cyanide solutions, but, like gold, is not acted upon sensibly if in large grains or sheets, but many of the ores of copper decompose cyanide solutions, some of them, such as the carbonates and oxides, so rapidly as to render the direct application of the cyanide process, for the extraction of gold, commercially a failure. In such cases some success has been attained by first leaching out the copper with a weak solution of sulphuric acid; washing the ore to displace the acid, and when necessary neutralizing the remaining acid by the addition of lime, and the subsequent treatment of the ore by the cyanide process for recovery of the gold. This process is said to have been introduced with considerable success at Barstow, Cal., on ores from Camp Rochester in San Bernardino county. Ores containing as high as 3% copper can sometimes be treated by cyaniding better than by any other process, but it as often occurs that an ore containing less than 1% copper will give much trouble, the copper accumulating in the circulating solution until it can no longer be used. Where copper becomes thus troublesome it is often better to use the electrical process for precipitation. There is considerable literature available on the subject of electrical precipitation of gold and silver from cyanide solutions.

The Nickel Plate Mine of British Columbia.

Written for the MINING AND SCIENTIFIC PRESS.

Within the past few years there has been developed, near the little mining village of Hedley, B. C., one of the richest gold mines in the world—the Nickel Plate of the Hedley Reduction Co, Ltd. Hedley is an obscure little place in the valley of the Similkameen river, at present off the line of railroad travel and up to the present time but little has reached the outside world concerning the Nickel Plate mines. In 1900 the mine came to the attention of M. K. Rodgers, who is the general manager, while he was in Victoria, B. C. For five years before finding the Nickel Plate, Mr. Rodgers had been in search of a large and profitable mining property for Marcus Daly, of Butte, Montana. In the furtherance of this desire to find a good mining property, he traveled many thousands of miles, examined over 500 mines and prospects, scattered over a good part of the world, and finally met the owner of the Nickel Plate at Victoria, when the mine was still in the prospective stage. The mine was visited with difficulty, for at that time there were no such conveniences of travel as at present. It "stood up" to critical superficial examination, there being little development, and eventually it passed to the present owners. The property comprises about twenty claims of fifty acres each.

The Nickel plate mill and office buildings are in the valley of the Similkameen, the mine being upon the mountain. The mine and the mill are connected by gravity tramway and electric railroad, the former 9000 feet long with a difference of 4300 feet altitude between terminals. The mill buildings and tramway are well illustrated by the accompanying engravings.

At the head of the gravity tram is an electric road, on which cars run between the ore bin and the mine—the cars running directly into the stopes. The cars descend by gravity to the upper loading terminal of the gravity road, and are hauled back to the mine by electric motor. On this line are twenty-two cars of two tons each.

The gravity tram has not got a uniform gradient, but varies between 10% and 66 8%. When first built this tramway was all in one section, but, owing to the frequent changes in grade, it was decided to operate it in two sections, which was found to be far more satisfactory. At the head of the upper section is a hoist driven by compressed air, which is connected with the winding drums of the rope. The function of this hoist is to hold the cars under constant control, and to equalize the uneven tension on the ropes, due to variable gradient. At the middle station the cars are detached and connected to the ropes of the lower section, thus dispensing with the necessity of reloading. At the lower end of the lower section, the cars run upon a tipple and dump automatically into a bin. Here the ore is reloaded into cars of five tons capacity, which deliver it to the breakers at the top of the mill.

The great difference in altitude between the mill and mine in that latitude makes a marked difference in the climatic conditions, there being about three months more summer at the mill than at the mine.

The ore, for most part, contains an auriferous mispickel, showing more or less free gold. The formation is greenstone, and in places this rock is sufficiently mineralized to constitute good pay ore, these mineralizations constituting the veins and ore shoots. Up to the present time the greater part of the ore is mined by open-cut and mill-hole method.

The reduction equipment comprises a complete stamp mill and cyanide plant, though all of the ore is not amenable to this treatment, some of it being smelting ore.

The mill is equipped with forty stamps, sixteen vanners and the usual rock-breaking machinery.

All power for the mine is generated by water, supplied by Twenty-mile creek. A flume 14,200 feet long was built to carry 1000 inches of water. A head of 406 feet is obtained at the lower power house. A 20-inch steel pipe carries the water to the wheels. A second pipe line, 16 inches in diameter, runs to wheels at the mill, operating under a head of 207 feet. At the main power house are the large compressors, electric dynamos, etc.

The mill is built on benches graded into the solid rock of the hillside. It is a gravity mill throughout. It covers a floor space of 43,500 square feet. The ore is delivered to a large bin at the upper part of the mill, 150 feet above the lowest floor. From this bin it passes through a chute to a grizzly, with bars spaced 1 inch apart. The oversize goes to a jaw crusher set to break to 1½ inch. The ore passes another grizzly, the oversize going to a smaller breaker, from which it drops onto a belt conveyor, which delivers to a second conveyor running longitudinally with the mill bins and at right angles to the first. By means of the second belt the ore is distributed wherever required in the bins below, keeping the ore supply evenly distributed. These bins have a storage capacity of 2000 tons, which is sufficient to supply the stamps for twelve or more days. There are three water wheels attached to the mill—one for the breakers, one for the stamps and the third for concentrators. The mill has at present forty stamps, but sixty more are to be added. The stamps weigh 1050 pounds and drop 7 inches ninety-two times per minute. The discharge is 6 inches above the die, through a 20-mesh brass wire screen. About four tons per stamp are crushed each twenty-four hours. The free gold is caught by amalgamation inside the batteries and on the outside plates. It has been found advisable to increase the number of concentrating machines, there being at present two vanners to each battery of five stamps. This will be increased by the addition of eight more machines, and the new addition of sixty stamps will be similarly equipped. The concentrates are almost wholly mispickel, to the extent of 10% of the ore. The concentrates are at present being stored, until experiment demonstrates the best means of treatment—an important matter not yet determined.

The tailings are treated by the cyanide process, the plant covering a floor 220x50 feet. There are twenty-four tanks, 34 feet diameter and 6 feet deep. They are arranged in two series, one above the other, for double treatment. The mill force, including those in the power department, requires the services of thirty men.

*See illustrations on front page.

Gravity Tramway, Nickel Plate Mine, Hedley, B. C., 9000 Feet Long, 4300 Feet Fall.

The Nickel Plate Mine, Hedley, B. C.

THE veins of scheelite (calcium tungstate) recently discovered about 5 miles east of Randsburg, San Bernardino county, Cal., is said to be from 6 to 18 inches wide, and to carry about 30% tungstic acid throughout. The pure ore runs about 80% tungstic acid.

Cheap Gold Mining and Milling in the Black Hills.

Written for the MINING AND SCIENTIFIC PRESS by E. J. KENNEDY.

California and Montana have each furnished examples of remarkably cheap mining and milling in the years gone by, and some excellent records have been made in these and other Western States. It seems almost needless to state that these low costs have always been made where the mining was done by the open cut method. In California some of the deep mines operate at a cost not exceeding $2 per ton, but when the cost drops below $1 the open cut method may at once be surmised to be a factor in the case, even when the conditions are unknown to those at a distance from the mine.

In the Black Hills of South Dakota are the largest gold mines in the world, and the most extensive operations in the world under one company are those of the Homestake at Lead, in Lawrence county. There are other large mines in the Hills, particularly in Pennington county, and some of these latter are now making good records for low mining and milling costs, after years of idleness resulting from various causes. Among these is the Benedict mine, owned by the Golden West Mining Co. The property is situated in Hornblende district, at the head of White Weasel gulch, and the mill 2700 feet distant, at the forks of North Castle creek and the main Castle creek, in a heavily timbered region, and in the heart

of the southern gold belt of the Black Hills.

The writer undertook the development of this property three years ago, following the ore in development. Shafts, cuts, drifts and crosscuts were driven, mostly in ore, and the ore thus mined in the course of prospecting and development was hauled in wagons to a 10-ton Chile mill run by water power. This was an inexpensive prospecting outfit, costing about $900—mill, flume, water wheel, and everything connected with the plant, ready to run. The cost of hauling and milling in this somewhat primitive manner was about $1.25 per ton, the mining cost not being included, as it was charged to development work. The ore sent to mill ranged in value from $1.25 to $5 per ton, the average for the first summer season being $3.15 per ton. During that season—1902—about 100,000 tons of ore were blocked out, which was considered sufficient to warrant the extension of our plant.

A flume and pipe line were built, 2½ miles long, having a capacity sufficient to carry all the water of Castle creek. The head at the mill was 123 feet. This gives us 300 H. P., which is more than is at present required.

The cut at the mine is 270 feet higher than the mill, with which it is connected by aerial tram, which operates without the least trouble. Only one man—the loader—is employed on this line. During the present season (1905) five men mine 100 tons of ore daily from an open cut. Cars are run close to the face of the cut, where rough, portable plank chutes are set up, and the ore is caved into the cars, which run on a level with the top of the ore bin at the upper terminal of the tram.

We also have a belt conveyor for certain places. This is quickly adjusted at any desired place and the ore is shoveled onto the belt, and this is also delivered into the upper terminal bin. The belt conveyor takes its power from the upper terminal wheel, the tram being connected to the power at the mill—everything being operated by water power owned by the company. The buckets are dumped automatically into a large gyratory crusher at the mill, which is situated above an ore bin of 500 tons capacity. The mill crew consists of two men on day shift and one at night, the mill crushing 100 tons every twenty-four hours. No night crew is worked at the mine, the day shift easily keeping the mill supplied for the full period of twenty-four hours. In the event of any stoppage in mining the mill bin, containing 500 tons, and the bin at the upper terminal may be drawn upon, and are capable of keeping us going nearly a week.

Ordinarily our expenses for a day's operations at mine and mill are about as follows:

Five miners at $3 per day	$15 00
One loader at $3 per day	3 00
Two millmen at $4 per day	8 00
Superintendent at $5 per day	5 00
Total	$31 00

We have a large Chile mill, in which the wear on steel is very light. The cost of the mill steel, oil, repairs, etc., will not exceed $4 per day. This makes the cost of mining, transportation and milling 100 tons of ore daily but $35, or a cost per ton of 35 cents. This is a very low cost, and is, I believe, a record breaker for a $3 camp. Of course, the surrounding natural conditions are all in our favor. We have abundance of timber, free water power—more than is required; the ore is decomposed and soft and free milling, the tailings only being worth about 20 cents; no drill steel is required, as no drilling is necessary; little powder is used, the blasting being in crevices and in bulldozing larger masses. Altogether, we are at present fortunately situated. Later, as depth is attained, the expenses must increase somewhat, but then the glory hole system will be put into practice, and as gravity can still be utilized the additional cost is not expected to be prohibitive.

The formation here is hornblende and micaceous schist, with small lenses and veins of quartz, and broad silicified zones impregnated with auriferous pyrite and gold. This ore at the surface is oxidized and free milling. In depth the oxidation will gradually disappear, and we will then have a less simple and more expensive metallurgical problem to contend with than at present.

The Hornblende district, in which this property is situated, extends in a belt about 3 miles in width from the property of the Black Hills Copper Co., in the canyon of the main Rapid creek, at the northwest corner, to the Golden West property on the southeast. The postoffice for this district is Rochford, near which are the Stand-by, Montezuma, Alta-Lodi and a number of other mines.

A 260,000,000-GALLON WATER SUPPLY through a 240-mile conduit at a cost of $23,000,000 is the large project announced by the city officials of Los Angeles, Cal., says the Engineering News. The officials report that options on water rights and on conduit right-of-way have been secured and that the people will soon be asked to vote on the necessary bond issue. The source of the proposed supply is the headwaters of Owens river, on the eastern slope of the Sierras, in Inyo county, Cal. It is said that a concrete conduit, 15 feet wide and 9 feet high, is proposed, and that there will be about 17 miles of tunnel. It is expected that the provision of an abundant water supply will lead to the consolidation of outlying municipalities with Los Angeles, and in any event contribute materially to the growth of Los Angeles and vicinity. Wm. Mulholland is superintendent of the water works of Los Angeles and Owen McAleer is Mayor. In development of this water supply scheme an important part has been taken by Fred Eaton, M. Am. Soc. C. E., who has served as both city engineer and Mayor of Los Angeles.

The Ventilation of Mines.

NUMBER II.

USE OF COMPRESSED AIR FOR VENTILATING PURPOSES.—The air set free from the rock drills is without doubt a most useful addition to the stock of air in the mine, and is liberated where it is most wanted, at the place where the men are working. This portion of the compressed air, too, has done its mechanical work in actuating the drill, and has repaid as far as is possible the cost expended in compressing it. With air set free from the mains to blow out smoke the case is different, for the air which has been compressed at considerable expense is used without doing any mechanical work, and the quantity so liberated gives a very poor return for the cost expended on it. The commission questioned a great many witnesses as to what was the cost of the compressed air used for ventilation, and what proportion of the whole of the compressed air sent into the mine was used for this purpose as compared with that used through the rock drills, but only very vague replies were received, very few of the users of compressed air having apparently troubled to go into the matter. One witness said plainly he was afraid to go into the cost of ventilating in this manner, knowing that it must seem out of all proportion to the result obtained. The reason for using the compressed air, in spite of its admitted high cost, is that it is so convenient, the pipes having necessarily to be led through all the workings close to the "faces" and the hose pipes for the drills being available at any time for blowing out smoke.

To use any other system of ventilating requires the employment of a separate pipe system, or brattices, air sollars, or other means of dividing the air currents, and the very heavy blasting usual in our mines, where from thirty to fifty pounds of blasting gelatine are frequently fired in one round of holes, making it impracticable to carry any of these devices close up to the working points.

One Kalgoorlie mine superintendent, well known for able and economical management, held that notwithstanding the high cost of the compressed air it was cheaper to use it than to employ any of the other suggested methods, loss of time in fixing ventilating appliances and the cost of maintaining them in good order being, in his opinion, so great as quite to equal or even surpass the cost of the compressed air. It must be admitted that there is great force in this contention, and that the destruction of ventilating pipes and other appliances by the unavoidable heavy blasting is a very serious difficulty in their practical application. At the same time we must point out that the quantity of compressed air put into the working places is often very inadequate for their proper ventilation, and that, owing to its cost, there is a strong inducement to cut down the amount allowed to be used to the minimum that will permit the men to work. This is especially the case where the compressor is rather small for the needs of the mine and there is a pressing demand for air for the drills, a condition liable to recur from time to time as the mine extends and reaches nearer and nearer to the capacity of the compressor. While there is a general agreement of opinion among most of our witnesses that the air in the immediate vicinity of the machines is fairly good while rock drills are actually working, it takes very little calculation to show that the quantity of air put into the mine through the compressed air mains is altogether insufficient of itself for proper ventilation. Let us take the case of the Associated Mines at Kalgoorlie, which have a very fine large air compressor, designed for sixty drills, and stated to be able, with an expenditure of 1000 H. P., to compress 5000 cubic feet of free air per minute. According to the returns made to the commission by the manager, the amount of air ordinarily put into the underground workings is 1700 cubic feet of free air per minute, which supplies twenty drills and two air-winches, while about 100 cubic feet per minute are used in driving pumps. Taking the winches as using 300 cubic feet per minute, and neglecting leakages, the amount supplied to each drill would average 65 cubic feet per minute. The number of men underground is returned at 292, or, say, 100 men in one shift. The total amount of air per man put into the mine by the compressor, therefore, only averages 17 cubic feet per minute. Taking the men on the drills only, each drill having two men, the quantity per man averages 32½ cubic feet per minute. As each drill, when actually working, liberates probably over 100 cubic feet of air per minute, the average of 65 cubic feet must be much higher than the amount set free while the drill is not working, and the amount supplied to the men while setting up the machine must be very small. Usually the air is used for blowing out the smoke, and then is cut off, or almost so, while the men rig the drill. During this period the ventilation is often very deficient. The analyses made by Mr. Mann show that in point of fact, even when the drills are running, there are places where the ventilation is very far from perfect.

We do not wish to be understood to mean that in the instance quoted, and similar cases, the only ventilation in the mine is that from the compressed air, for as a matter of fact the principal air supply to these mines is obtained from natural ventilation. The figures quoted were meant to show that the compressed air by itself is a quite insufficient supply, and would not alone be able to maintain the air in a pure state. Usually there is a certain amount of air from the main airways slowly finding its way into even such places as are some distance from the main air currents, and gradually removing the vitiated air.

Many working miners hold the belief that air from the compressed air mains is inferior for breathing purposes to air sent in by other means, there being a common impression that the air has been in some way injured by compression.

The analyses made by Mr. Mann of samples of compressed air from the mines' ordinary supply show that this opinion is mostly a prejudice, the air being practically pure. The air in passing through the rock drill often receives a charge of atomized oil, as oil has to be used very freely in the drill to keep it in good running order. Besides the oil in the air there is also, however, at times a very offensive odor, probably due to organic matter in the pipes when they are laid, the composition used in making the joints, the finely divided oil from the compressor, and dust in the air compressed. The moisture in the air compressed is often incompletely condensed before the air enters the pipe system, and therefore condenses in the pipes, and lying in low parts of the pipe line it may become very foul and offensive. It is a not uncommon occurrence for such water to be blown out of the pipes through the drills. Occasional traps on the pipe line, automatically blowing themselves off when full of water, are therefore advisable.

(TO BE CONTINUED.)

Scientific Blasting.

Written for the MINING AND SCIENTIFIC PRESS.

Occasionally miners are required to perform difficult blasting operations, where buildings, flumes or other structures in the vicinity are endangered and must be protected. Experienced workmen can usually overcome these difficulties by the judicious pointing of holes and in careful use of powder. Not long since, in a city which it is needless to name here, it became necessary to remove a number of concrete piers which had been constructed in the basement of a large brick building. These piers were foundations of large size made from the best material by competent engineers, and had been placed in position as foundations for heavy machinery and had been in use for more than ten years. It became necessary to remove these foundations, and it goes without saying that it had to be done without injury to the building. The foundations were built on a concrete floor and extended upward to about the level of the main floor of the building—the street level. For a day or two men were engaged in the attempt to remove these concrete piers with picks, hammers and gads, but they made most discouraging headway. One of those interested made inquiry of an expert miner, H. P. Gordon, and asked if the foundations could be mined or blasted out. Mr. Gordon examined the proposition, felt satisfied the job could be done and accepted the contract. After drilling two holes and firing them, there seemed to be no longer an experiment in the proposition and the contract was undertaken. For a period of thirty-five days from four to seven miners were employed under direction, drilling and blasting these concrete piers. In addition to these miners, a crew was employed sledging the larger pieces of concrete and in shoveling the debris into wagons. During this time a total of 470 holes were drilled in the concrete, the most of them being 30 inches deep, a few of them being short block holes. Sixteen hundred feet of fuse, 170 pounds of No. 2 dynamite and 470 detonators were used. The result of these municipal mining operations was 740 wagon-loads of broken concrete, about 2220 tons. The work was continued to a successful conclusion, no damage whatever was done, and these unusual operations did not even attract the notice of passersby nor of those occupying the neighboring buildings. All work was done during the day, the blasting being accomplished whenever the round of holes was ready. As no permit was obtainable for work of this character, it had to be done secretly; but no unusual precautions were observed. The holes were well tamped with moist clay and each hole was loaded with nearly one and a half sticks of powder, the block holes requiring less.

The success of this operation shows that blasting may be successfully accomplished without damage within the limits of a metropolitan city if the necessary care is exercised in the work.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

NUMBER V.

Written by T. H. OXNAM.

GENERAL REMARKS.—The total quantity of solution passing through the zinc boxes during 1904, divided by the quantity of sands for the same period, shows that, for each ton of sand treated, 3.27 tons of solution left the leaching vats, of which 2.63 tons were weak solution and 0.64 ton strong solution.

It is found in the treatment, that large quantities of the weaker solution give more satisfactory results than small quantities of the strong solution, and it is always made an important point to pass as much weak solution through a charge as possible. Experience has demonstrated that in a given length of treatment a rapid leaching rate and a large quantity of solution is more efficient than a slower leaching rate and a consequently lesser quantity of solution. The solution pipe lines and launders occasionally become quite choked in places with scale deposited from the solution. This scale, taken from lines carrying precipitated solution, contained from a trace of $1 of gold and from 1 to 7 or 8 ounces of silver per ton. The scale deposited from the unprecipitated solution usually runs higher, several assays taken having averaged about $5 of gold and 18 ounces of silver per ton.

Ordinarily the solutions do not become excessively fouled. They usually contain small percentages of iron and manganese in addition to the zinc compounds present. Alkaline sulphides are very rarely or never noticed in solution. Sulphocyanides and ferrocyanides appear to be constantly present, however, in fair quantities. The average of a number of determinations made at various times gives about 0.41% of ferrocyanides and 0.048% of sulphocyanides.

The sands charged averaged about 0.09% of latent acidity, and, as a rule, they contain no free acid.

The concentrates produced are sold to the same company that buys the cyanide precipitates. When making the original cyanide experiments on this ore, a good deal of time was devoted to an attempt to treat the concentrates by cyanide, but without success. Experiments on both raw and dead-roasted concentrates reduced to various degrees of fineness, by leaching and agitation, for varying periods of time, up to 34 days, and using solutions varying from 0.2% to 2% of KCN, proved entirely unsatisfactory.

Table VI gives the working costs for milling and cyaniding during 1904. It should be remembered that the cost of all supplies is considerably increased by the very heavy freight transportation expenses, as well as by the duties placed by the Mexican Government on most of the supplies used. The freighting facilities have not improved any since the change in the milling operations—the difficulties of transportation remaining as described earlier in this paper, and being, therefore, the source of an unusually heavy portion of the expenses for the supplies.

TABLE VI.—WORKING COSTS PER TON.

Milling—	
Supplies	$0.640
Labor	0.357
Lubricating	0.023
Assay office (labor and supplies)	0.035
Concentrating	0.092
Power (ditch, maintenance and supplies)	0.234
Salaries	0.264
Miscellaneous (lighting, etc.)	0.018
Management and general expenses	0.336
Total	$1.999

NOTE.—$1.999 Mexican currency during this period was equivalent to $0.95 gold.

Cyaniding—	
Cyanide (2.95 lb. @ $0.63)	$1.859
Zinc (0.96 lb. @ $0.30)	0.288
Lime (4.33 lb @ $0.0118)	0.051
Other supplies	0.050
Labor	0.329
Salaries	0.371
Assay office (labor and supplies)	0.036
Power (ditch, maintenance and supplies)	0.017
Miscellaneous (lighting, etc.)	0.004
Management and general expenses	0.186
Total	$3.191

NOTE.—$3.191 Mexican currency during this period was equivalent to $1.52 gold.

The cost of realization on cyanide precipitates has not been included in above cyanide working costs. This cost is naturally very high, the quantity of precipitates produced being much greater in proportion than that produced when treating gold ore only, while the treatment charges per ton of ore are no less. Transportation expenses on the precipitates are also very heavy. In addition to this comes the heavy item of Government bullion taxes.

The average cost of realization on cyanide precipitates per ton of ore cyanided is as follows: Government taxes, $0.84; treatment charges (including transportation expenses), $1.06. Total, $1 90.

The cost of realization on the concentrates produced is also unusually high on account of the heavy transportation expenses and Government bullion taxes. The average cost of realization per ton of ore crushed is as follows: Government taxes, $0.35; treatment charges (including transportation expenses), $1.08. Total, $1.43.

TREATMENT OF SLIMES.—As before mentioned, the accumulated and currently produced slimes are now being treated in a separate plant by a system of agitation and decantation, centrifugal pumps being used as the means of agitation. The slime plant consists essentially of the following parts and accessories:

Four agitation and four decantation vats, all provided with conical bottoms and each being connected with its own separate centrifugal pump; two solution tanks placed at the head of the zinc boxes, which receive the solution from the decantation vats; four sets of zinc boxes and three solution sumps, which receive the solution leaving the zinc boxes; one special solution tank placed at a higher level than the rest of the plant and used principally to supply solution to the pump bearings under pressure; two ordinary 3-inch centrifugal pumps, used only for pumping solution from the sumps to any desired vat or to the upper solution tank just mentioned, they being so connected up that either pump can be used should the other get out of order. Each pump is run by a friction clutch pulley, which enables it to be started or stopped in a moment, independently of the other pumps. A small 14x15-inch friction-geared hoist is used to convey the slimes from the slime pits to the agitation vats. The entire plant is run by a 5-foot Pelton wheel, making about 115 revolutions per minute and operating under a head of 81 feet, using a 4-inch nozzle. Water power is obtained by means of a 14-inch riveted steel pipe, tapping the main pipe line supplying power to the mill. This 14-inch pipe line was brought in by mule back, riveted in 10-foot lengths, although some difficulty was experienced in its transportation.

Figs. 4 and 5 give plan and section of the slime plant.

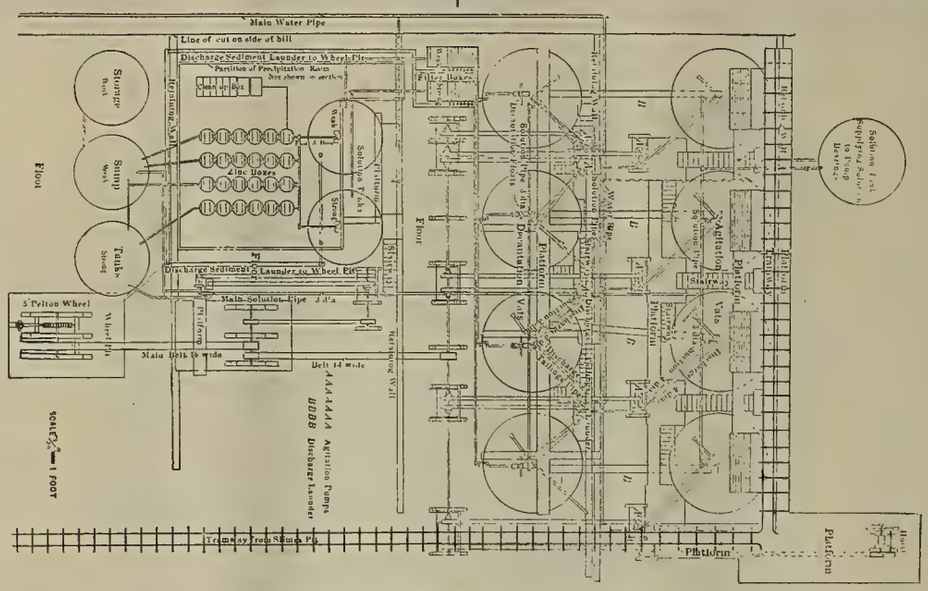

Fig. 4.—Plan of the Slime Plant, Palmarejo, Mexico.

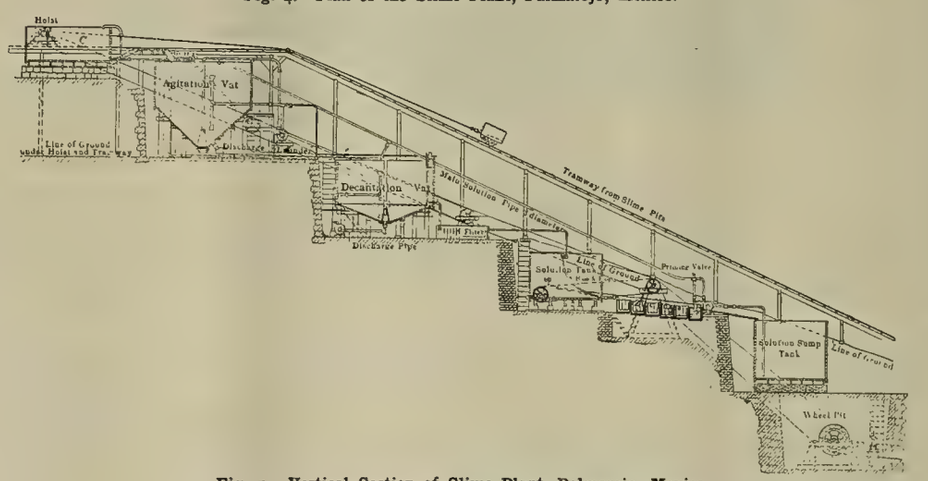

Fig. 5.—Vertical Section of Slime Plant, Palmarejo, Mexico.

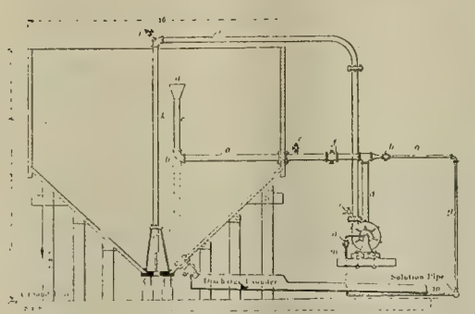

Fig. 6.—Agitation Vat and Pump Connections.

The method of treating the slimes is quite similar to that ordinarily practiced by agitation and decantation and consists briefly in giving the slimes about a two days' agitation in the agitation vats, with from two to three times their weight of cyanide solution, followed by another two or sometimes three days' treatment in the decantation vats, during which latter portion of the treatment the charge, after having been sufficiently agitated with the addition of slaked lime, is allowed to settle as much as practicable, and the supernatant clear liquor is deposited and passed through the zinc boxes. This operation of agitation, settling and decantation of clear solution is repeated as many times as permissible within the time limit of the treatment, ordinarily being but three or four decantations.

The material being treated, when dried to from 20% to 25% of moisture, is quite tough and of the consistency of soft putty. It contains, however, a certain percentage of very fine sands, and, when viewed in vertical section, presents a somewhat stratified appearance. As previously mentioned, it cracks on long drying into layers almost absolutely impervious to leaching.

DESCRIPTION OF THE PLANT.—The four agitation vats, made of 3-inch redwood throughout, are provided with conical bottoms, slanting at 45°. As shown in Fig. 6, each vat has an inside diameter of 15 feet 7 inches, and their vertical depth from top of side staves to the iron casting at point of conical bottom is 15 feet, the inside depth of vertical side staves being 7 feet 3 inches. Each agitation vat is connected with a special manganese-steel lined, 4-inch centrifugal pump, which runs at a speed of 900 revolutions per minute. The pump is connected with the vat by the 4-inch suction pipe, a, which enters the vat through the side staves about 6 inches above their juncture with the bottom staves and extends nearly to the center of the vat, where it is connected by means of a movable elbow, b, with a short piece of 4-inch pipe, c, provided at the free end with a good-sized screen or strainer, d, made of ¼-inch sheet iron, punched with a number of 1-inch holes; this short piece of pipe, together with the screen, is of such a

*Trans. Amer. Inst. Min. Engrs.

length that when being lowered the screen will just clear the bottom staves. The screen is provided with a small iron ring, to which is fastened a piece of rope, by means of which it can be raised and lowered.

Just outside of the vat, the suction pipe is provided with an air cock, e, which admits air to the material going through the pump. This air cock, however, is very rarely used at the present time. The service cock, f, permits the shutting off of the material from the pump at any time it may become necessary—as, for instance, to repack the stuffing-box or to examine the interior of the pump. The 2-inch pipe line, g, provided with the valve, h, connects with the upper solution tank.

When it becomes necessary to shut the pump down for any length of time, either at the conclusion of the agitation of the charge or at any time during the treatment, the 2-inch valve, h, is opened and the service cock, f, is closed, thus allowing clear solution only to pass through the pump. The friction clutch pulley running the pump is now thrown out of clutch, and after the pump has stopped the valve, h, is closed. By this means is avoided the accumulation in the pump interior of solid matter that would naturally be deposited, when the pump is stopped for any length of time, from the slimy material ordinarily passing through it.

The 4-inch discharge pipe, i, of the pump is provided with a small bibb-nosed pet-cock, j, a few inches from the body of the pump, by means of which samples can readily be taken of the material passing through the pump. The discharge-pipe passes over the top of the vat, and at a point vertically over the center of bottom casting is provided with an elbow and drop pipe, k, which reaches to within about 15 inches of the bottom casting. This pipe is held firmly in position by means of an iron clamp and four legs made of 0.75-inch bolts fastened to the bottom casting and which serve as a tripod. The distance of the lower end of this discharge pipe from the bottom of vat is a matter of some importance in the agitation, and a number of experiments made along this line have indicated that the best satisfaction is obtained at a distance of 15 inches from the bottom casting.

Different shapes of discharge ends, or nozzles, have been tried at the lower end of the drop pipe, but experience so far has shown that the plain 4-inch pipe end gives as satisfactory results as any other shape. The discharge pipe of the pump tends to act as a siphon when the pump is stopped at any time during the agitation, and would therefore cause inconvenience when repacking the stuffing-box or making any necessary repairs. To prevent this, air is admitted to the pipe by opening the small air cock, l, tapped into the elbow at the upper end of the drop pipe. This air-cock, l, is also frequently used to allow the entrance of air into the charge being agitated, it being found more preferable for this purpose than the air-cock on the suction pipe. (It might be supposed that when this air cock is open during the agitation, a steady stream of the material passing through the discharge pipe would be ejected through it; and with regard to the air cocks similarly situated on the pump connections of the decantation vats, such is the case. As regards the pumps connected with the agitation vats, however, the effect is found to be quite the reverse, and rather a strong air suction usually occurs when this air cock is open.)

The pump bearing nearest the pump shell is tapped with a small pipe line, m, provided with the valve, n, which connects with the upper solution tank previously mentioned. By this means, the bearing is supplied with clear solution under pressure and the wear on the shaft and bearing is greatly reduced. At the commencement of operations, clear water was supplied to the pump bearings and was also used for cleaning out the pumps and for priming, when necessary. It was soon found, however, that the quantity of water added in this way increased the volume of stock solution very appreciably, and, of course, an equal quantity of weak cyanide solution had ultimately to be run to waste. Not only did this cause an unnecessary, mechanical consumption of cyanide, but the quantity of water added through the pump bearings naturally reduced the strength of the working solution in the vat under operation, with a consequent deleterious effect on the percentage of extraction. The quantity of solution that will be added to a vat during the usual period of agitation (from 40 to 44 hours), when the shaft and bearing is a little worn, is surprising, amounting in some cases to 15 tons, even when the greatest care is exercised. The amount of solution added in this way is naturally the least just after the pump has been equipped with a new shaft and new liners, and the bearing re-babbitted. On an average, however, the quantity of solution added to each charge through the pump bearings is from five to six tons. The agitation pumps in use, while in most respects proving very satisfactory, have nevertheless certain defects in their design, which contribute largely to the rapid wearing of the shaft and the bearing next to the pump shell, and also to the wearing of the interior, renewable manganese-steel wearing parts. The life of these parts naturally varies somewhat, but ordinarily it becomes necessary to equip a pump with a new shaft and certain portions of the manganese-steel wearing-parts and to re-babbit the bearing, about every six weeks. The pumps are equipped with a pulley having a 6-inch face, but it is found preferable to use a 4-inch belt, since this reduces the weight on the pump shaft with a consequent decrease in its wear, while a 4-inch belt runs the pump equally as well as a 6-inch one. Wire lacing is used on all the belts.

The results of the sizing test in Table VII represent an average of those obtained from the material treated up to the present time.

TABLE VII. SIZING TEST ON SLIMES

Size of Material.	Weight	Assay Value.		Percentage of Total Values Contained	
		Gold.	Silver	Gold	Silver.
	%.	Value	Ozs.	%.	%.
Retained on 80-mesh	1 1	$2 38	14 22	0 63	0 77
Retained on 100-mesh	2 7	2 06	13 60	1.35	1.81
Retained on 120-mesh	5 6	1 96	13 02	2 66	3 59
Retained on 150-mesh	3 1	2 27	14.14	1.70	2.16
Retained on 200-mesh	2 7	2 16	13.10	1.41	1.74
Passed 200-mesh	84 8	4 54	21 68	93.22	90 52
Totals	100 0			100.97	100 59

Assay value of material was $4.13 of gold and 20.30 ounces of silver per ton.

(TO BE CONTINUED.)

THE PROSPECTOR.

The rocks from A. J. T., Yerington, Nev., are: No. 1, a very much altered and indeterminable rock containing copper carbonate; the white mineral is calcium sulphate (gypsum). No. 2 is a much altered diorite, also showing a little copper carbonate; gypsum is also associated with this rock. No. 3 is an oxidized ore from near the surface; it consists principally of iron oxide; the iridescent colors are due to copper; there is gypsum in this ore also. No. 4 is a much altered eruptive rock carrying a large percentage of iron sulphide (pyrite). No. 5 consists chiefly of epidote (light yellowish-green mineral), specular iron (the brilliant metallic mineral), and calcium carbonate (the white mineral); the general appearance of the rock suggests a greatly altered diorite, in which there has been a secondary formation of several foreign minerals.

The silver ore from P. F. G., Mascota, Mexico, contains several complex combinations of silver with sulphur, antimony, etc. The larger piece contains principally the ore known as freieslebenite, a complex combination of silver, antimony, lead and sulphur. In this there is also a very little black sulphide of silver. The smaller and darker piece contains considerable argentite (silver glance) or black silver sulphide, and also combinations of silver, sulphur, antimony, etc., occurring so intermixed as to render their determination individually almost an impossibility.

The three mineral specimens from Roosevelt, Idaho, have been determined as follows: No. 1. Quartz-porphyry. No. 2 is an acid eruptive in which stratification seems to have been induced by pressure. The rock presents many of the characteristics of aplite, though stratification is unusual in that rock. The determination of small specimens is often difficult. No. 3 is vitrophyre, a variety of volcanic glass.

The rock samples from Havilah, Cal., are: No. 1 is a micaceous schist, heavily stained with iron oxide. No. 2 is a very siliceous mica schist which evidently at one time contained pyrite, the oxidation of which has rendered the rock porous, giving it a honeycombed appearance; the rock may be gold bearing. No. 3 is a silicified dike rock (probably pegmatite), the greater part of the quartz having a flint-like appearance. No. 4 is also a siliceous dike rock, through which are scattered numerous feldspar crystals; this rock may also be gold bearing.

The minerals from Forest Hill, California, are: No. 1, steatite. No. 2 is a basic rock altering to a talc schist. No. 1 evidently represents a further state of alteration of the same rock. These rocks may be, as stated, gold bearing, as similar auriferous rocks occur elsewhere in California.

The white crystallized rock samples from Gisborn, Utah, are calcite (calcium carbonate). The specimens are only translucent. When perfectly transparent this mineral is known as Iceland spar and possesses the remarkable property of double refraction. That is, two images are seen in looking through it. This property is taken advantage of in microscopic petrography by the use of what are known as nicol prisms, which are made from clear, transparent, flawless Iceland spar.

An End-Dumping Wheelbarrow.

Written for the MINING AND SCIENTIFIC PRESS by MATT. W. ALDERSON.

A number of articles illustrating self-dumping arrangements for the hoisting bucket have been published. Recognizing the value of self-dumping skips, under certain conditions, the writer has, nevertheless, been unable to see where they can be made of practical value to the prospector. In hoisting it does not seem possible to arrange to dispense with at least one man on the surface and, as a general rule, this man is the man who has time to spare. After receiving one bucket and sending an empty one down, he has time to empty several buckets while the one below is being filled. A self-dumping arrangement only gives him more time, which he has no use for. This would not be true, of course, if the bucket below was loaded from an ore pocket or bin, but prospectors generally would not put in such, till developments warrant. What seems to be needed is arrangements to save work below.

Where hoisting is done, after the shaft is sunk, by windlass, whip or whim, it is not often that the ground is hoisted as broken. Generally a man will work several days breaking, throwing the dirt behind him, till there is accumulation to justify a day's hoisting. It is of advantage to have the dirt to be hoisted as near the shaft as possible and when one gets his level in over 20 feet he cannot throw the material behind him and near the shaft without great waste of time in walking back and forth. And he can not pile it close behind him very long and leave room to get out. As a remedy for this condition of affairs the writer has used a wheelbarrow so arranged as to dump conveniently on the end instead of at the side. This contrivance, illustrated here-

End Dumping Wheelbarrow.
